ing is continued too long, a yellow color develops in the concd. soln. which is due to volatilizable AsI_3. To avoid loss of AsI_3, the usual custom is to pay no attention to the final color of the *concd. soln.* and to stop boiling when, as Gooch recommended, a certain vol. is reached. It is pointed out here that the color can also be avoided by limiting the amt. of KI added for the reduction of the As. S. L. B. Etherton

Ceric salts for quantitative analysis: determination of antimony in the presence of arsenic. Hans Rathsburg. *Ber.* **61B**, 1663–5(1928).—Tervalent Sb solns. can be titrated with 0.01–0.05 *N* $Ce(SO_4)_2$ solns. and the end point detd. electrometrically or by the decolorization of methylene blue, Congo red, methyl orange or methyl red. Then, if tervalent As is also present, further titration will give indication of a second electrometric end point or the As can be titrated with $KBrO_3$ soln. W. T. H.

The oxalate method for separating calcium and magnesium. William T. Hall. Mass. Inst. Tech. *J. Am. Chem. Soc.* **50**, 2630–3(1928).—The presence of Mg makes it necessary to add more $C_2O_4^{--}$ than would be necessary otherwise to ppt. CaC_2O_4 completely, but if this excess is made too large the subsequent pptn. of $MgNH_4PO_4$ will be incomplete unless NH_4 salts are first removed by ignition. W. T. H.

The use of gelatin oleate mixtures for the demonstration of small amounts of calcium. Samuel Amberg, John Landsbury and Frances Sawyer. The Mayo Foundation. *J. Am. Chem. Soc.* **50**, 2630–3(1928).—Na oleate in glycerol at p_H 7.2–7.8 can be used to detect 0.0005 mg. of Ca in 1 cc. but the reaction is not sp. for Ca. W. T. H.

Determination and separation of chromium, iron, aluminum and phosphorus. K. K. Järvinen. *Z. anal. Chem.* **75**, 1–27(1928).—Various methods were tested for the oxidation of Cr and it was found that the oxidation by Br_2 in cold alk. soln. was most satisfactory. To accomplish this add Br_2 to the acid soln. and then make alk gradually and finally heat to complete the oxidation. For the sepn. of Fe and Al it is convenient to ppt. the Fe by NH_4OH and Na_2S, filter and ignite the ppt. to Fe_2O_3. An iodometric method for the detn. of Fe is based upon treatment of the ferric soln with KI, boiling off the liberated I_2 and absorbing it in NaOH: after adding acid, the I_2 in the distillate can be titrated with thiosulfate. For the analysis of a mixt. contg about 0.1 g. of Cr and corresponding quantities of Fe, Al and some P_2O_5 the following procedure is recommended: To 100–200 cc. of the soln. add 1–2 cc. of Br_2 and add NaOH slowly until about 10 cc. is present in excess. After about 15 mins. dissolve the ppt. in the least possible quantity of HCl and again make alk. Then make acid once more, heat on the water bath, add 50–100 cc. of water and boil off the excess Br_2, using moist iodo-starch paper to test the vapors. To the hot soln. add 10–20 cc. of 2 *N* $(NH_4)_2HPO_4$ (at least 1 mol. for each atom of Fe and Al) and ppt. $FePO_4$ and $AlPO_4$ by adding NH_4OH dropwise. Cool, dil. to exactly 250 cc., mix and filter. Make half of the filtrate strongly acid with H_2SO_4, using about 5 cc. concd. acid for each 100 cc. of soln. Add KI and titrate the I_2 liberated by the $Cr_2O_7^{--}$ with thiosulfate. Dissolve the phosphate ppt. in HCl, transfer the soln. to a non-tubulated retort, add 2 g. of KI and distil off one-half of the liquid (50–100 cc.) while keeping the neck of the retort immersed in 10 cc. of 2 *N* NaOH dild. with 50 cc. of water Cool, make acid and titrate with thiosulfate. In another portion det. the PO_4^{---} content and the Al by difference. W. T. H.

Gravimetric determination of fluorine as calcium fluoride using membrane filters. G. G. Kandilarow. *Ber.* **61B**, 1667–71(1928).—The gravimetric detn. of F^- has always proved a difficult problem and the customary procedure has been to ppt. $CaCO_3$ and CaF_2 together in order to get a filtrable ppt., subsequently dissolving out the $CaCO_3$ by treating the ignited ppt. with AcOH, after which another ignition and weighing is necessary. If a membrane filter is used it is unnecessary to ppt. $CaCO_3$ together with the CaF_2. To transfer the CaF_2 ppt. to a crucible, it is necessary first to dry the filter and ppt. in a suitable vacuum desiccator. Moreover, if the soln. contains some NO_3^- anions, the CaF_2 ppt. will coagulate more promptly. For the detn. of F, therefore, it is recommended to add to the original soln. of fluoride, 0.5–1.0 g. of $NaKCO_3$, neutralize with HNO_3 until methyl red begins to change color, boil off CO_2 and continue adding HNO_3 until, on heating, the yellow color of the indicator does not return. Then make distinctly acid with the 1–2 drops of dil. HNO_3, add a slight excess of $CaCl_2$, heat nearly to boiling and allow to stand overnight before filtering with the membrane filter. Dry the filter an hour in a vacuum desiccator, transfer the ppt. to a crucible and heat 30–40 min. in an elec. furnace at about 500°. W. T. H.

Colorimetric iron determination with potassium thiocyanate. L. S. van der Vlugt. Central Lab. Volksgezondheid, Utrecht. *Chem. Weekblad* **25**, 495–6(1928).—The presence of salts, particularly phosphates and sulfates, influences the color intensity

of $Fe(CNS)_3$. More thiocyanate ions and higher acidity counteract this effect. For practical purposes at the salt concn. of city water it was found that the following procedure gave dependable results. In a 300-cc. Erlenmeyer flask acidify 100 cc. water with 10 cc. dil. H_2SO_4 (1:5) and add 3 to 4 cc. 5% iron-free $K_2S_2O_8$. Boil for 5–10 min.; if the soln. is not then colorless, add more persulfate and boil again. Cool, filter, transfer to a 100-cc. colorimeter glass, fill up to 90 cc. and add 10 cc. 20% KCNS. Immediately compare the color with standards obtained by increasing quantities of ferric soln. + 4 cc. 5% $K_2S_2O_8$ and quantities of acid and KCNS equal to those of the treated soln. Mohr's salt is recommended as standard for iron. The limit of accuracy is 0.1 mg. Fe per l. B. J. C. VAN DER HOEVEN

Cupferron. Notes on its use in quantitative analysis. GRABER. *Ing. chim.* **16**, 87–93(1928).—A method is given for the detn. of Fe, Ti, Al and Cr and the use of cupferron for the sepn. of the rare earths is discussed. P. THOMASSET

Determination of iron in red lead. H. HEINRICHS. *Z. angew. Chem.* **41**, 450–3 (1928).—The usual method of detg. Fe in red lead by dissolving the sample in HNO_3, pptg. the Pb as $PbSO_4$, and weighing the Fe as oxide gives low results owing to the insoly. of part of the Fe in HNO_3 and to adsorption of $Fe_2(SO_4)_3$ by the $PbSO_4$ ppt. Correct results may be obtained by the following colorimetric method: 10 g. of the sample are mixed with 25 cc. of a cold satd. soln. of $NH_2OH.HCl$, and the mixt. is boiled for 10 min. with 50 cc. of HCl (d 1.19). The $PbCl_2$ is dissolved completely in 400 cc. of boiling water and the soln. set aside overnight. The liquid is decanted, evapd. to 100 cc., and again allowed to crystallize. The second filtrate is treated with NH_3, the $Fe(OH)_3$ ppt. collected and dissolved in HCl, and the Fe detd. colorimetrically with thiocyanate. A blank test should be carried out using the same quantities of reagents as in the analysis. A small, gray, spongy residue after dissolving the sample in the acid mixt. is metallic Pb, the presence of which is objectionable in red lead used for glass frits. B. C. A.

Determination of very small quantities of nitrogen. RUDOLPH EHRENBERG. Univ. Göttingen. *Z. ges. exptl. Med.* **56**, 466–9(1927).—The digestion is carried out in the usual manner. The distn. app. is of quartz with ground joints, the distg. flask having a capacity of 15 cc. making 25 cc. including the condenser. The receiver holds 10 cc. and before distn. 5 cc. 0.001 *N* $Pb(NO_3)_2$ is added, and 3 cc. 15% NaOH to the distg. flask contg. the digested mixt. The mixt. is distd. for 15 min. and the flame is adjusted so that 3.5 cc. distillate comes over. The pptd. $Pb(OH)_2$ is centrifuged down and 1 cc. of the clear liquid is pipetted into a centrifuge tube and 0.5 cc. radioactive 0.001 *N* $Pb(NO_3)_2$ and 0.5 cc. 0.001 *N* K chromate satd. with NaCl are added. Equal fractions of radioactive and inactive Pb are pptd. This is centrifuged and 1 cc. pipetted onto a watch crystal, and left on the water bath for at least 9 hrs., after which the radioactivity is detd. with the electrometer, and compared with a control. Samples contg. only a few thousandths of 1% N can be detd. by this method. F. L. DUNN

New method for quick mercury analysis that is simple and reliable. LETUS S. STRICKLER. *Eng. Mining J.* **126**, 539(1928).—The method described is a modification of the Holleway-Eschka method for detg. Hg in ores. By changing the flux, the presence of free S or of org. matter does no harm. This flux consists of 5–6 g. of CuO, 2–3 g. of powdered Ag and 2 g. of CaO. The precautions necessary to get proper amalgamation of the Ag sheet by the volatilized Hg are mentioned. W. T. H.

Micro-estimation of potassium as cobaltinitrite. ALBERT LEULIER, LÉON VELLUZ AND HENRI GRIFFON. *Bull. soc. chim. biol.* **10**, 891–904(1928).—The history of the K cobaltinitrite reaction is reviewed with 26 references to the literature. The author's technic fills about 3 pages and yields results with an error generally less than 3%. L. W. RIGGS

Micro-chemical determination of phosphorus. Notes on the modifications of Denigès method by V. V. Ciurea. IULIU VOICU. Univ. of Bucarest. *Bull. soc. chim. Roumania* **10**, 50–5(1928); cf. *C. A.* **22**, 3370.—Instead of the colorimetric comparison of standards, C. has recommended the use of Cl_2 water for the titration of Denigès compd., the amount of Cl_2 for complete discoloration being in ratio with the quantity of P present. V. cannot check C. and finds that a great excess of Cl_2 is necessary to cause only partial discoloration and concludes that this method cannot be used as given by C. P. THOMASSET

The predetermination of the sulfur content of cast iron from cupola-furnace practice. BERNHARD OSANN. Bergakademie Clausthal. *Giesserei Z.* **15**, 204–6(1928).—The S content of cast Fe may be detd. in advance by classification calcns. Hitherto unpublished results and examples of the calcns. are given. In the first method it is assumed that 30% of the S in the coke unites with the Fe and the rest is in the gases;

25% of the S in the charged Fe is slagged, while 75% remains behind. Calcns. using these assumptions are verified exptly., the differences between the 2 being 0.003% (av.). In a 2nd. method of representing the desulfurization process, it is assumed that the S content of the Fe is increased by the unvaporized S in the coke; of this increase 12% is slagged. The desulfurization process is shown in its true sequence by this method. However, the first is simpler. J. BALOZIAN

Studies on the exact determination of thorium after precipitation as hypophosphate. FRIEDRICH HECHT. *Z. anal. Chem.* **75,** 28–39(1928); cf. *C. A.* **22,** 3861.—Th is pptd. completely in a soln. contg. 10% HCl, or more, as $ThP_2O_6.11H_2O$ by means of $NaH_2P_2O_6$. The ppt. is practically insol. in water, acids and alkali hydroxide solns. The elements most likely to ppt. with the Th are Zr, Hf, Ce and Ti. It is shown here, however, that there is little danger with respect to Ce because hot HCl reduces Ce^{++++} to Ce^{+++}. It is not yet clear whether there is any interference by Zr or Hf. Upon strong ignition the ppt. of ThP_2O_6 is changed to ThP_2O_7 but it is very difficult, if indeed possible, to ignite to a const. wt. although it is now shown that the wt. of the ppt. is a little too high even after very prolonged ignition. It is best, therefore, to convert the ppt. to some other form for weighing. Rosenheim's method, as modified by Wirth (*C. A.* **6,** 3379), is suitable for decompg. the hypophosphate ppt This consists in digesting the ppt., together with the filter, with 50 cc. of hot concd. H_2SO_4 and gradually adding small portions of $NaNO_3$. Then, instead of expelling practically all of the H_2SO_4 as Rosenheim did (*C. A.* **7,** 38) enough acid is left so that a clear soln. is obtained on dilution, from which the Th can be pptd. as oxalate. Or, if there is objection to this, the H_2SO_4-H_3PO_4 soln can be neutralized with NH_4OH and the Th ppt. filtered off. Rosenheim assumed that this ppt. was $Th(OH)_4$ but this is not true. It contains considerable PO_4 and is more likely to be $Th_3(PO_4)_4$. This ppt. dissolved in dil. HCl and from the soln. $Th(C_2O_4)_2$ can be pptd. It is also possible to get an approx. value for the ThO_2 content by fusing the hypophosphate ppt. with $NaKCO_3$, leaching with water, filtering and igniting the insol residue. It is far better, however, to fuse this last residue with $K_2S_2O_7$, dissolve this melt in dil. HCl, ppt. the Th as $Th(C_2O_4)_2$ and ignite to ThO_2 This last method is fully as good as the procedure recommended by Rosenheim and by Wirth W. T. H.

The acid decomposition of iron carbide in the presence of ferrous ions. R. STENKHOFF. *Mitt. Versuchsanst. Deutsch. Luxemburg Bergwerks- u. Hütten A.-G. Dortmünder Union* **2,** 75–81; *Chem. Zentr.* **1927,** II, 1456.—As a supplement to the work of Schenk and Stenkhoff (*C. A.* **21,** 2091) the following may be said: For the *detn. of* Fe_3C by the isolation of the carbide from carbide-contg. iron correct values are obtained only when strongly dissociated acids are used as solvents, and when the proper care is taken frequently to renew the acid. Concg. the ferrous salts effects a sepn. of C from Fe_3C. It is well to use acids which do not have a tendency to form complexes and which are not of an org. nature. The C elimination may be increased by the formation of complexes and the adsorption of org. acids may give high results in the detn. of carbide C J. S. REICHERT

The determination of free lime. H. RATHKE. Tech. Hochschule Breslau. *Tonind. Ztg.* **52,** 1318–21(1928).—The defects of the Emley NH_4OAc method including the harmful effect of the water set free in the reaction and the inconvenience of titrating a boiling soln. have been largely overcome by using 0. 1 *N* tartaric acid in abs. alc. Add to 0.5 g. of cement or other finely ground solid 10 cc. of abs. glycerol, shake well and heat until white fumes appear. Dil. with 100 cc abs. alc., add a few drops phenolphthalein and titrate. The addn. of a little water does not have much effect on the detn. of free CaO in cement or in monocalcium-and dicalcium silicates, but has a bad effect when working with Thomas slag. F. O. ANDEREGG

Separation and titrimetric determination of lime and magnesia. R. SCHMIDT. Landesanst. f. Wasser-, Boden- u Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig* **3,** 21–3; *Chem. Zentr.* **1927,** II, 1879.—The well-known method of sepn. of CaO and MgO by means of Blacher's palmitate soln. is described in detail. C. C. DAVIS

New method of volumetric estimation of mercuric oxide. PRIYADARANJAN RÂY AND JYOTIRMOY DAS-GUPTA. *J. Indian Chem. Soc.* **5,** 483–5(1928).—When HgO is shaken with cold $Na_2S_2O_3$ soln. the following reaction takes place: $HgO + 2\,S_2O_3^{--} + H_2O \longrightarrow [Hg(S_2O_3)_2]^{--} + 2OH^-$. By titrating the liberated hydroxyl with standard acid, a measure of the HgO, is obtained. W. T. H.

Analysis of lead-zinc ores. FRANCESCO GAETA. *Rass. min. met. ital.* **68,** 71–2 (1928).—A procedure based on standard methods is given. C. C. DAVIS

Analysis of electrolytically deposited lead peroxide by the method of Lux. M. G.

MELLON, W. F. REED AND H. L. WILKINS. Purdue Univ. *Proc. Indiana Acad. Sci.* **37**, 255–8(1927).—The method of Lux consists in dissolving the PbO_2 in HNO_3 and a known quantity of oxalic acid, finally titrating the excess of the latter with $KMnO_4$. Difficulty was encountered by the fading of the first apparent end point. Better results were obtained when the oxalic acid was replaced by H_2O_2. S. L. B. E.

The analysis of chlorine bleaching solutions. H. SUNDER. *Chimie et industrie* **Special No.**, 467–70(April, 1928).—A description of the method of detg. NaOH, Na_2CO_3, $NaHCO_3$, Cl_2, NaOCl, HOCl, $NaClO_3$ and $NaClO_2$. The detn. of HOCl and NaOCl is based on the reactions: HOCl + 2KI = KCl + KOH + I_2 and NaOCl + 2KI + H_2O = NaCl + 2KOH + I_2, which were indicated by Lunge, but have apparently not been used to date. It is carried out by adding KI and then a measured excess of 0.2 *N* HCl, titrating the liberated I_2 with $Na_2S_2O_3$ and then the excess HCl with NaOH. If T = cc. 0.1 *N* $Na_2S_2O_3$, t = cc. 0.2 *N* HCl added, t_1 = cc. 0.2 *N* NaOH in the back titration, x = cc. 0.1 *N* HCl required to neutralize the KOH formed from HOCl and y = cc. 0.1 *N* HCl required to neutralize the KOH formed from NaOCl, then $x = T - 2(t - t_1)$ cc 0.1 *N* $Na_2S_2O_3$ for HOCl and $y = 4(t - t_1) - T$ cc. 0.1 *N* $Na_2S_2O_3$ for NaOCl. A. PAPINEAU-COUTURE

Colorimetric determination of carbon disulfide in gas. G. G. DÉSY. Koppers Co Lab., Pittsburgh. *Proc. Am. Gas Assoc.* **1927**, 1440–1.—The gas to be tested (100–1000 cc.) is passed through Bowen bulbs contg. 10% KOH soln., and through concd. H_2SO_4, into a gasometer or Tutweiler buret, where its vol. at atm. pressure is noted. The gas is then passed through a bent glass tube with capillary outlet, into 1 cc. of alc. KOH contained in a test tube. After a measured vol. of gas is passed, the soln. is washed into a Nessler tube, dild. to about 48 cc. with distd. H_2O, and made slightly acid with AcOH, using phenolphthalein as indicator. Four drops of 0.05 *N* $Cu(OAc)_2$ soln. are added and the contents mixed. The color so obtained is compared with the color from known amts. of the standard Et xanthate soln. which has had the same treatment. The method is accurate to about 10% of the amt. of CS_2 present. J. H. P.

Practical method for the analysis of chromite. BERTHET. *Chimie & industrie* **Special No.**, 133(April, 1928).—On the assumption that a sample of chromite may be contaminated with serpentine or other mineral, a scheme is given for the detn. of loss on ignition, SiO_2, S, Fe, Al, Mn, Ca and Mg as well as Cr. The original attack of the mineral is by Na_2O_2 in a Ni crucible, a sep sample being used for the detn. of Cr. The aq. ext. of the melt is used for the detn. of S in the other sample and the insol. residue used for the other detns. The details of the procedure are, for the most part, along conventional lines A. PAPINEAU-COUTURE

Determination of small amounts of carbonate in the presence of sulfide and chloride, with particular reference to the analysis of metallic corrosion products. W. H. J. VERNON AND L WHITBY. *J. Soc. Chem. Ind.* **47**, 255–8T(1928).—For decompg. the sample use a mixt. of H_3PO_4, d 1.75, and half as much water. H_2S is best absorbed by powd. Cu (not reduced by H_2) and HCl by *p*-nitrosodimethylamine. These 2 absorbents proved far better than those usually recommended. W. T. H.

Analytical application of iodine trichloride for oxidations and of sodium formate for reductions. ERWIN BIRK. *Z. angew. Chem.* **41**, 751(1928).—By satg. I with Cl_2 at −79° it is easy to prep. ICl_3 and this substance is a useful oxidizing agent. *E. g.*, it dissolves Au and U chlorides very easily. Na formate is easily oxidized to $Na_2C_2O_4$ at the fusion temp. so that it can be used to advantage as a reducing agent in many dry reactions. Thus by fusion with Li_2CO_3 and $NaCO_2H$ it is easy to detect W in the dry way, forming a Li-W bronze. W. T. H.

The electrometric titration of hypochlorite and hypochlorite-carbonate mixtures. A RIUS AND V. ARNAL. *Trans. Am. Eletrochem. Soc.* **54** (preprint), 7 pp.(1928).—An electrometric method was developed using 0.1 *N* NaOH soln. Results indicate that neutralization occurs in a 1-stage reaction. Since the potential of a Cl electrode varies with the p_H of the soln., hypochlorite, alkali carbonate and free hydroxide can be detd. by a single titration. In the presence of NaOH and Na_2CO_3 in soln, 3 distinct inflection points on the titration curve were obtained corresponding to NaOH + $^1/_2Na_2CO_3$; NaOH + Na_2CO_3; and NaClO, resp. C. G. F.

The determination of hydrogen iodide by the distillation method and the behavior of ferric chloride with silver iodide. ALEXANDER JÜRGENS. *Pharmacia* **1926**, No. 5, 3 pp.; *Chem. Zentr.* **1927**, II, 1494.—The property of a $FeCl_3$ soln. to liberate I from AgI on boiling was used as a method for the *detn. of I.* The app. consisted of a round-bottom flask with a constricted neck and a glass tube sealed on a Peligot tube with definite calibration, and cooling device of the same height as the tube. The I compd. is dissolved, treated with the $FeCl_3$ soln., the I is distd. over and collected in

a KI soln., and titrated with 0.1 to 0.02 *N* $Na_2S_2O_3$ soln. The results are not very accurate because the action of boiling water converts some of the I into HI which escapes titration. The $FeCl_3$ soln. must be free from Cl and HNO_3. The authors state that a complete conversion of AgI into AgCl and I is not effected with $FeCl_3$ soln. Only about 25% of the AgI is converted. J. S. REICHERT

The analysis of nitrates. P. RISCHBIETH. *Chem.-Ztg.* **52,** 691(1928).—Directions are given for detg. the nitrate content in 2 ways on one and the same sample. For a sample of nitrate weighing about 0.1 g., carefully weigh out a little less than 0.17 g. of Fe wire. Connect with a CO_2 generator, add 3 cc. of concd. HCl and sweep out all air from the app. Heat the flask till all of the Fe dissolves. Cool and add the weighed sample of nitrate. Heat till the dark color disappears from the Fe^{++} soln. and pass the evolved NO, with the aid of the CO_2 stream, into a gas pipet contg. KOH soln. Det. the quantity of nitrate by the vol. of NO obtained in the pipet and by the vol of $KMnO_4$ required to react with the excess Fe salt. The 2 values should agree. W. T. H.

Rapid method for the determination of phosphine in acetylene. R. GRANJON. *J. acétylène* No. **61,** 572-5(July-Aug., 1927); *Chimie & industrie* **20,** 258(1928).—C_2H_2 is passed through 10 cc. of a standard soln. contg. 10 g. $HgCl_2$ and 20 g. KCl per l. (which absorbs PH_3 with formation of a yellowish ppt. of Hg phospho-chloride) until the reagent has been exhausted (shown by the darkening of $AgNO_3$ paper suspended over the soln.). If *V* is the no. of l. of C_2H_2 required, $1.5 \times 100/V = PH_3\%$ by vol. A. PAPINEAU-COUTURE

Titrimetric determination of sulfuric acid in water. A. DOBROWSKY. *Allgem Z. Bierbrauerei Malzfab.* **55,** 277-8; *Chem. Zentr.* **1927,** II, 2701.—The $BaCrO_4$ method of Andrews in the form proposed by Windisch and Lampe (*Analyst* **48,** 66(1923)) for the detn. of H_2SO_4 was investigated thoroughly. It was found that with very low concns of SO_4 the errors are great. The results are always too low, which may be explained by the fact that the $BaCrO_4$ used in the detn. contains other sol. Ba salts which also ppt. the sulfate. Since Ba salts are removed only with difficulty from the $BaCrO_4$ ppt., a method for the prepn. of pure $BaCrO_4$ is given. The chief value of the prepn lies in the fact that not more than $^1/_3$ of the quantity of Ba salt necessary for the pptn is taken and the K_2CrO_4 soln. contg. pure NH_3 is used. C. C. DAVIS

Gravimetric determination of sulfuric acid in the presence of antimony. S. VON FINÁLY. *Z. anal. Chem.* **75,** 17-27(1928).—The purpose was to find a more convenient, and possibly more accurate, method for detg. S than by fusion in the dry way. The results of numerous expts. indicate that in the presence of Sb^{+++} the following directions give good results. Evap. the soln. to dryness on the water bath, if, as is often the case, a sulfide ore has been decompd. by Cl_2. To the residue add 0.5 g. of NH_4Cl 4 g. of tartaric acid, 70 cc of *N* HCl and 30 cc. of water. Heat to boiling and add dropwise 10 cc of 10% $BaCl_2$. After allowing the soln. to stand for 24 hrs., filter on a cotton mat, wash with 25 cc. of cold water, then with 25 cc. of hot water and finally with 10 cc. of pure acetone. Drain off the acetone with the suction pump, dry 2 hrs. at 130° and weigh the $BaSO_4$. According to the wt. of the ppt. apply a correction which varies quite uniformly from +0.9 mg. with 20 mg. of $BaSO_4$ to −4.5 mg. with 0.4 g. of $BaSO_4$. W. T. H

A contribution to the determination of water by distillation with hydrocarbons. W. BOLLER. *Chem.-Ztg.* **52,** 721(1928).—To prevent drops of H_2O adhering to the sides of the measuring tube, the condenser tube is drawn to a fine point which reaches nearly to the bottom of the measuring tube. J. H. MOORE

Methods and newer electrodes for p_H determinations. TH. FASOL. *Collegium* **1928,** 435-40.—A review. I. D. C.

The p_H of distilled water. C. VAN DER HOEVEN. *Collegium* **1928,** 440 3. The H electrode cannot be used to measure the p_H of distd. H_2O because of low cond. Quinhydrone itself gives an acid reaction and so gives "acid errors" which are smaller the greater the buffer action of the soln. The quinhydrone electrode did not give p_H values above 5.4 for boiled distd. H_2O. The colorimetric method may give appreciable errors but good results can be obtained with low concns. of neutralized indicator solns. (*e. g.*, with the Na salt of methyl red). I. D. C.

Quantitative organic microanalysis. RALPH T. K. CORNWELL. *J. Chem. Education* **5,** 1099-1108(1928).—A popular account of the work of Pregl and others on the analysis by combustion of a few mg. of material. W. T. H

Partial decomposition of alkaline chlorides in the course of incineration, in particular of nitrogenized organic materials. P. FLEURY AND P. AMBERT. *Bull. soc. chim. biol.* **10,** 869-79(1928); cf. *C. A.* **22,** 2182.—Ten cc. of a 3% soln. of NaCl was

mixed with 0.4 g. of org. material and was evapd. to dryness on the water bath. The residue was heated slowly in a muffle furnace to dull redness until the ash was white. When necessary, the ash was taken up with water, evapd. and reheated. To the cooled ash was added 10 cc. of 0.1 *N* H_2SO_4 and phenolphthalein and the mixt. was allowed to stand on the water bath for several min. when the excess of H_2SO_4 was titrated back with standard $Ba(OH)_2$ soln. In this way 22 common org. substances were tested, of which 18 showed an alky. equiv. ranging from 0.18 for benzoic acid to 4.56 cc. 0.1 *N* NaOH for xanthine. There was a loss of Cl. The alky. of the residue appeared to be due to a mixt. in variable proportions of Na_2CO_3 and NaOH. The results account for the alky. of the ash of the gastric juice and of other org. substances contg. Cl.
L. W. RIGGS

Destruction of organic matter in toxicological investigations. P. E. HEEDERIK. Univ. Leiden. *Pharm. Weekblad* **65**, 861–79(1928).—A comparison was made of As and Hg detns. in horse meat, using various methods for destroying org. matter. In the Fresenius and von Babo method the destruction is incomplete, but if the As is distd. as $AsCl_3$ the recovery is practically quant., whereas detn. as $Mg_2As_2O_7$ gives too low results Hg is recovered quant. The Kerbosch method gives good results for As if the app. is slightly modified, but low results for Hg. Addn. of $KMnO_4$ as catalyst is not advantageous. The Wagenaar method is more rapid, but the large amt. of H_2SO_4 used is objectionable; const. attention is required and recovery of Hg is incomplete. In the Magnin and Stettbacher methods the destruction is incomplete and only small quantities of material can be used. Recovery of Hg is good. The Fresenius and von Babo method gave the most satisfactory results. A. W. DOX

Determination of carbon and of hydrogen without a catalyzer. IVAN MAREK. *Bull. soc. chim.* **43**, 910–2(1928).—A simple and effective *elec. furnace* is described for combustion of org. substances and suitable absorbing vessels are shown. W. T. H.

The determination of free carbon in tars, pitches and the like. E. BERL AND H. SCHILDWÄCHTER. *Brennstoff-Chem* **9**, 137–8(1928).—A 5-g. sample is heated in an autoclave with 200 cm. tetralin at 240–250° under 12–13 atm. for 2 hrs. The soln. is now filtered on a 3/5–7 Schott glass filter crucible, washed with 50 cm. hot tetralin and 100 cm. C_6H_6, dried at 150° in CO_2 and weighed. Insol. matter found is free C.
J. D. DAVIS

Note on the detection of carbon dioxide. G. ELTESTE. *Z. angew. Chem.* **41**, 1858(1928).—One difficulty concerning the detection of CO_2 from a leaky bomb or from a small quantity of carbonate is that the air always contains some CO_2. If filter paper is wet with 0.1 *N* $Ba(OH)_2$ contg. 1 cc. of 1% phenolphthalein per 10 cc., it will, while moist, be bleached by contact with more CO_2 than the air contains. Then if the paper is allowed to stand in the air, the color will slowly return. In the first case $Ba(HCO_3)_2$ is probably formed but on standing $BaCO_3$ results. W. T. H.

Remarks on my method of carbon dioxide analysis. H. LUNDEGÅRDH. *Z. Pflanzenernähr. Düngung. B.* **12A**, 1–4(1928).—Polemic between L. and Hasse and Kirchmeyer (*C. A.* **22**, 4698) over the method of detg. the CO_2 content of air.
R. M. BARNETTE

Answer to H. Lundegårdh's remarks on his method of carbon dioxide analysis. P. HASSE. *Z. Pflanzenernähr. Düngung. B.* **12A**, 4–7(1928).—Cf. preceding abstr.
R. M. BARNETTE

Analysis of gaseous mixtures containing carbon dioxide, carbon monoxide, hydrogen and methane. WILLIAM E. J. BROOM. *J. Soc. Chem. Ind.* **47**, 276–8T(1928).—With the aid of a Toepler pump and two gas-pipets, which are described, a mixt. of CO_2, CO and CH_4 can be analyzed accurately with small quantities of reagents. First the CO_2 is removed by 60% KOH soln. and then the gas is passed over CuO heated to 200–300° which, in the course of 90 min., oxidizes the H_2 to water and the CO to CO_2 without affecting the CH_4. The diminution in vol. thus gives the H_2 and after another absorption by KOH only CH_4 remains. W. T. H.

Determination of small quantities of acetic acid in air in presence of carbon dioxide. V. KUNI AND S. NIKOLSKI. *Gigiena truda* **1927**, 41–3.—The air is drawn through 0.1 *N* NaOH soln., the change in alky. is detd. and the carbonate pptd. as $BaCO_3$; the latter is detd. titrimetrically or as $BaSO_4$ B. C. A.

Differentiation between citric, tartaric and oxalic acids. D. I. PERIETZEANU. *Bull. soc. chim. Roumania* **10**, 49(1928).—Copper acetate gives with tartaric acid a ppt. of Cu tartrate difficultly sol. in dil. HCl and in 30% NaOH. Eight mg. of tartaric acid will give a ppt.; citric acid gives no ppt.; oxalic acid gives a ppt. of Cu oxalate insol. in 30% NaOH but sol. in an excess of concd. HCl. P. THOMASSET

new **process for estimating citric and tartaric acids.** F. PIRRONE. *Riv. ital.*

essenze e profumi. **1928,** 101-2.—Heat slowly to boiling in a 300–400-cc. flask 0.0500 g. tartaric acid or 0.0388 g. citric acid with 50 cc. 0.1 *N* KIO_3 and 25 cc. concd. H_2SO_4, evap. to 30 cc., cool, add 100 cc. distd. H_2O and evap. again to 30 cc. Cool again, add 100 cc. distd. H_2O and 10 cc. 30% KI, and titrate free I with 0.1 *N* $Na_2S_2O_3$. If *n* cc. $Na_2S_2O_3$ soln. is used, (50-*n*)0.00125 and (50-*n*)0.0009722, resp., are the quantities of tartaric acid or citric acid by wt. in the sample. R. SANSONE

The influence of the extract content on the determination of alcohol. ERICH WALTER. *Getränke-Ind.* **1927,** 285-6; *Chem. Zentr.* **1927,** II, 2428.—The quantities of ext. present influence the hydrometric detn. of small quantities of EtOH to such an extent that the results are inaccurate and misleading. Therefore it is advisable to det. the EtOH only after distn. C. C. DAVIS

Report on (the determination of) ether. G. C. SPENCER. Bur. of Chemistry and Soils. *J. Assoc. Official Agr. Chem.* **11,** 360-2(1928).—The Somogyi method (*C. A.* **20,** 1577) has been modified by passing the vapors through jacketed tubes, the 1st one (in which the alc. is absorbed) being maintained at 50° and the 2nd (in which the Et_2O is absorbed and oxidized) at 0°. The method was not found to be dependable for such mixts. as may be obtained by distn. from medicinal prepns., but it may give satisfactory results for known mixts. of anhyd. alc. and Et_2O. A. PAPINEAU-COUTURE

Critical remarks on the determination of glycerol by the acetin method and the sources of error. P. FUCHS. *Chem.-Ztg.* **52,** 737. O. BERTH. *Ibid;* cf. *C. A.* **21,** 2391; **22,** 3863.—The error sometimes attributed to acetylizable matter in the NaOH used is probably due, for the most part, to CO_2 absorbed by the NaOH; this influences the end point with phenolphthalein in the cold. F. shows at considerable length how proper allowance for this error can be made. B.'s method is to make an empirical correction. W. T. H.

Determination of the ortho position in certain phenolic compounds by color test. FRITZ WISCHO. Univ Graz. *Pharm Monatshefte* **9,** 169-71(1928).—Color reactions have been studied and results tabulated when solns. of pyrocatechol, adrenaline, pyrocatechuic acid, gallic acid, pyrogallol, tannin, apomorphine, guaiacol, salicylic acid, saligenin and anthrarobin are treated with $FeCl_3$, Jorrison's reagent, aq NH_4 vanadate, and V_2O_5 in dil. HCl, H_3PO_4 and $H_2C_2O_4$, resp While positive results with the V reagents may be obtained on unknowns, they should be considered only as aids in detecting *o*-phenolic compds. Resorcinol, quinol, orcinol and phloroglucinol do not respond to the V reagent. W. O. E

Color tests for simple sugars. SAN-YIN WONG. Univ. Hongkong. *Chinese J Physiol* **2,** 255-8(1928).—The α-naphthol, resorcinol, phloroglucinol and orcinol tests for sugars gave more delicate results if the reagent was dissolved in glacial AcOH and the test was made in an AcOH medium. Moreover, the resultant color remained clear and could be used for spectroscopic examn. or color comparison L. W. RIGGS

Color reactions of the carbohydrates. LAD. EKKERT. Univ. Budapest. *Pharm. Zentralhalle* **69,** 597-600(1928); cf. *C. A.* **21,** 875, 4018.—A study of the colors produced by the interaction of the carbohydrate (arabinose, xylose, rhamnose, glucose, mannose, galactose, fructose, sucrose, lactose, maltose, dextrin, glycogen and amylum soluble) 0.005 to 0.01 g. with an equal amt. of phenol (resorcinol, α-naphthol, β-naphthol, morphine, codeine, phenacetin, α-naphthylamine), and 1 cc. concd. H_2SO_4. The colors develop slowly at room temp. but more rapidly on careful warming. W. O. E

Rapid method of glucose determination. W. D. HORNE. *Planter Sugar Mfr* **81,** 1(1928).—A modification of the well-known cyanide method using Rice's expended Meissl-Hiller table. The alk. Cu soln. after boiling is made immediately to vol. without cooling and an aliquot pipetted for titration with standard KCN soln. The pipet used is graduated especially to facilitate correction and compensation for temp. J. F. BREWSTER

Estimation of reducing sugars. WM. L. O. WHALEY. *Planter Sugar Mfr.* **80,** 41-4(1928).—With either Fehling, Violette or Soxhlet alk. Cu soln., carefully standardized, the method offers the novel feature of titration without the use of outside or added indicator, the flocculated appearance and color of the pptd. Cu_2O serving to indicate the end point. A table is included giving buret readings corresponding to wts. of reducing sugars. J. F. BREWSTER

Determination of atropine in the presence of morphine. L. E. WARREN. U. S. Food, Drug and Insecticide Administration. Washington, D. C. *J. Assoc. Official Agr. Chem.* **11,** 377-81(1928).—In the U. S. P. method for detg. codeine sulfate in morphine sulfate, the morphine is fixed with excess NaOH and the liberated codeine is shaken out with $CHCl_3$. This method is inapplicable as such for detg. atropine, scopolamine, or other solanaceous alkaloids, in the presence of morphine, because most com. mor-

phine salts contain notable proportions of codeine salts as impurities which would contaminate the extd. solanaceous alkaloid. W. suggests a method (technic described in detail) consisting in sepg. the total alkaloids into 2 fractions, one contg. morphine only and the other the total alkaloids not morphine, by the U. S. P. method for detg. codeine in morphine sulfate, then destroying the atropine in the total alkaloids not morphine by the Fuller method, detg. the total remaining alkaloids, and estimating the atropine by difference. Use of the method showed that experienced analysts familiar with the technic can obtain results within about 10% of the truth, while inexperienced analysts are apt to fail. Moreover the method is long and time-consuming.

Detecting carbon monoxide. EDGAR W. HULTMAN. U. S. 1,684,587, Sept. 18. Test papers are employed contg. $PdCl_2$ and a hygroscopic salt such as $CaCl_2$ to keep the papers moist.

Determination of moisture in powders. T. S. BONVECH. Russ. 3747, Oct. 31, 1927. The finely powdered material is weighed and mixed with an equal wt. of CaC_2. The temperature increase indicates the amt. of water. Tables must be calcd. beforehand for each material showing the increase in temp. for a given amt. of moisture.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

The atomic volume relations in certain isomorphous series. II. A. F. HALLIMOND. *Mineralog. Mag.* **21**, 480–4(1928); cf. *C. A.* **22**, 189.—The isomorphous replacement of one element by another in a pair of cryst. salts is generally accompanied by a change in the mol. vol. The present contribution deals with the vol. relations of salts of Ca, Sr and Ba with O, S, Se and Te, and it is shown that these relations correspond with those for K, Rb and Cs with the halogens. The effect of substitution in the NaCl lattice varies with the size of the cell but the variation does not attain the proportion required for a law of const. radii. The results obtained might be expressed as showing minor deviations from the law of Retgers where mol. vol. is additive in a series of isomorphous mixts.
W. F. HUNT

Mineralogical communications. K. JOHANSSON. Reichmuseum, Stockholm. *Z. Krist.* **68**, 87–118(1928).—*Gudmundite* is a new mineral belonging to the marcasite group. It resembles arsenopyrite in phys. properties and crystn. Analysis gave: Fe 26.79, Ni trace, Sb 57.31, S 15.47, Sn 99.57%, corresponding to FeSbS. The axial ratio is 0.6729:1:1.1868. *Haematophanite* is a new mineral with the following compn.: PbO 73.26, FeO 0.22, MnO 0.29, CaO 0.26, MgO 0.06, K_2O 0.17, Na_2O 0.38, Fe_2O_3 22.01, $FeTiO_3$ 0.20, Cl_2 2.17, H_2O 0.73, insol. 0.42, sum 100.17, corresponding to the formula $Pb(Cl,OH)_2{\cdot}4PbO{\cdot}2Fe_2O_3$. It occurs singly or in aggregates of platy crystals, with a mica-like cleavage, color dark red-brown, streak yellowish red, hardness 2–3; sp. gr. 7.70, uniaxial—. Analyses and crystallographic descriptions are also given for *plumboferrite* ($PbO{\cdot}2Fe_2O_3$) and *jacobsite* $(Mg,Mn)Fe_2O_4$. X-ray data are included, with the following conclusions [for which insufficient data are given. ABSTRACTOR]: 42 (?) mols. of plumboferrite in a hexagonal cell with a = 11.86 and c = 47.14 A. U., 3 (?) mols. of haematophanite in a tetragonal cell with a = 7.801 and c = 15.23 A. U. Jacobsite is cubic, with a = 8.42 A. U., and has a spinel type of structure, with the lower symmetry O_4 because of the partial replacement of Mn by Mg. Descriptions

and analyses are also given for a *manganomagnetite* and an *andradite garnet*.

Spectral analysis of minerals. F. LÖWE. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55**, 291–8(1926–7); cf. *C. A.* **22**, 44.—The use of the quartz spectrograph in mineralogical studies is described. J. F. SCHAIRER

The spectroscopic detection of minute amounts of impurities in minerals. G. O. WILD. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55**, 488–508(1926–7). J. F. S.

The minerals of the Chibina and Lujavr tundras on the Kola peninsula. A. E. FERSMAN. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55**, 36–46(1926–7); *Am. Min.* **11**, 289–99(1926).—Analyses of calcio-ancylite, cerapatite, ussingite, pectolite, eudialyte, eucolite, yuksporite, lamprophyllite, aenigmatite, mangan-neptunite, ramsayite, murmanite, rinkolite, lovtschorrite, loparite, astrophyllite, ranite and titanite are given with data on their origin and occurrence (cf. *C. A.* **19**, 2011). J. F. SCHAIRER

Supplement to the knowledge of the minerals of Jugoslavia. FRAN TUĆAN. *Ann. Géol. Pénins. Balkan* **9**, 77–83(1927); *Mineralog. Abstracts* **3**, 541.—Descriptions with chem. analyses are given of: asphalt (sp. gr. 1.890) from Prugova, Dalmatia; quartz sand from Perna, Croatia; ocher from Rudine, Croatia; and tetrahedrite from Mracaj, Bosnia. J. F. SCHAIRER

New Saxony mineral occurrences. A. TETZNER AND F. EDELMANN. *Jahrb. Berg und Hüttenw. Sachsen* **100A**, 49–72(1926); **101A**, 70–122(1927); *Mineralog. Abstracts* **3**, 539.—Notes to supplement Frenzel's book on the minerals of Saxony (1874). *Normannite* is a name left in manuscript in the Freiburg collection by A. Weisbach for a basic bismuth carbonate, $3Bi_2O_3.CO_2$, occurring as brown globular aggregates in the Wolfgang Maassen mine at Neustädtel near Schneeberg.
J. F. SCHAIRER

Appendix to the "Mineralogical Tables" of P. Groth and K. Mieleitner for the years 1921–7. New mineral names. WALTHER FISCHER. *Sitzungsber. Abhandl. Naturwiss. Gesell. Isis, Dresden*, **1928**, Festschrift Richard Baldauf, pp. 1–19; *Mineralog. Abstracts* **3**, 469.—An alphabetical list giving each mineral, its chem. formula, crystal system and bibliographical reference. J. F. SCHAIRER

The question of monoclinic diaspore. I. I. TANATAR. *Bull. Geol.-Min. Circle, Dnepropetrovsk Mining Inst.* p. 9, **1927**; *Mineralog. Abstracts* **3**, 473.—Errors in the optical description of the "monoclinic diaspore" (to which the name *tantarite* has been given) are pointed out. The monoclinic symmetry of the mineral has been confirmed.
J. F. SCHAIRER

Allochromism, morphotropism and structure of a mineral, especially precious stones. R. KLEMM. *Fortschritte Mineral. Kryst. Petrog.* **12**, 47–8(1927).—A brief discussion of the structure and coloring materials of minerals and gem stones. J. F. S.

The so-called emerald triplets from Muzo and their optical anomalies. F. BERNAUER. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **54**, 205–42(1926).—Emeralds from Muzo, Columbia, show a hexagonal core surrounded by 6 sections with fibrous structure. The sectors are sometimes separated by carbonaceous inclusions. Approx. chem. analyses are given. D. = 2.648–2.709. Optical properties are given. Some tiny artificial crystals show a similar structure. J. F. SCHAIRER

Chemistry of garnets. FRANZ HERITSCH. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55**, 60–91(1926–7).—Ninety-five published analyses of garnet are recalcd. to mol. % of the individual garnet mols. and arranged in groups according to compn. The compns. are plotted on triangular diagrams showing the degree of miscibility of the several mols. The relation of the garnets to rock types is discussed. J. F. S.

Mineralogical synthetic studies of sapphires (sapphirin). E. DITTLER. Univ. Wien. *Z. anorg. allgem. Chem.* **174**, 342–54(1928); cf. *C. A.* **22**, 3363.—The H_2O content varies from 0.31 to 1.60%. The analysis of sapphirin from Vol Codera (on a hygroscopic H_2O-free basis, ex. 100°) is: SiO_2 15.21, TiO_2 0.25, Al_2O_3 61.76, FeO 4.32, MnO 0.12, CaO 0.49, MgO 16.25, H_2O + 1.60%. No B was found. The mineral decomposes before fusion occurs. The mineral fuses at 1580 ± 5° to a greenish mass. A phase-rule diagram, showing the regions of occurrence of cordierite, sillimanite, spinel, corundum and periclase, is given. The compn. of 6 minerals is included.
J. H. P.

The crystal structure of topaz. LINUS PAULING. Calif. Inst. Tech. *Proc. Nat. Acad. Sci.* **14**, 603–6(1928); cf. Leonhardt, *C. A.* **18**, 648.—By making use of the coördination theory of ionic crystals, a structure for topaz was derived which agreed satisfactorily with the exptl. data. The fundamental polyhedra for topaz were assumed to be an octahedron of anions (O and F) about each Al ion and a tetrahedron of O ions about each Si ion. The anion-anion distance detg. the length of a polyhedron edge

was taken to be 2.72 A. U. throughout. By piling these polyhedra together one struture was found, the unit of which approximated that observed for topaz.

L. W. RIGGS

Synthetic turquois. M. K. HOFFMANN. *Fortschritte Mineral. Kryst. Petrog.* **12,** 45(1927).—Synthetic *turquois* was made by heating to 100° a very finely powdered mixture of malachite ($^1/_2$ mol.), $Al(OH)_3$ (6 mols.) and concd. phosphoric acid (2 mols.). Turquois decomposes into CuO and other products above 200°. J. F. SCHAIRER

Alumohydrocalcite—a new species. G. A. BILIBIN. *Mém. Soc. Russe Min.* [2], **55,** 243–8(1926)(English Summary); *Mineralog. Abstracts* **3,** 472.—A mineral called *alumohydrocalcite* was found in the Khakassky district, Siberia. It has the appearance of chalk, is brittle, sp. gr. 2.231. Analyses give the formula $CaO.Al_2O_3.2CO_2.5H_2O$. It is readily sol. in acids. Boiling H_2O causes sepn. of $CaCO_3$ and $Al(OH)_3$. It consists of microscopic radially-fibrous spherulites. $\alpha = 1.485$, $\beta = 1.553$, $\gamma = 1.570$, $2V = 50–55°$, optically negative. The dehydration curve shows breaks at 180–190°, 350° and less distinctly at 740–800°. The formula is written $CaH_2(CO_3)_2.2Al(OH)_3.H_2O$ analogous to that of dundasite. The mineral is related to dawsonite and hovite. It appears to have been formed by the action of $CaH_2(CO_3)_2$ on allophane. Attempts to prepare it artificially were unsuccessful. J. F. SCHAIRER

Bodenbenderite, a new mineral from Argentina. E. RIMANN. *Sitzungsber. Abhandl. Naturwiss. Gesell. Isis, Dresden,* **1928,** Festschrift Richard Baldauf, 42–51; *Mineralog. Abstracts* **3,** 472.—Albite-fluorite veins in the Sierra Chica, Sierra de Cordoba contain penninite, mica, helvite, garnet, vesuvianite and a new garnet-like mineral called *bodenbenderite.* The new mineral occurs as flesh-red dodecahedra. It is optically isotropic with an index of refraction greater than 1.77; sp. gr. 3.3–3.5; H = 6–6.5; fuses to a black slaggy glass. A complete analysis is given. After deducting 16.7% of impurities the analysis gives the formula $4RO.R_2O_3.3RO_2$ or $(Mn, Ca)_4Al[(Al,Yt)O][(Si,Ti)O_4]_3$ which is compared with that of beckelite. The compn. is also expressed as a mixt. of plazolite and vesuvianite. J. F. SCHAIRER

Kolbeckite, a new mineral from Saxony. F. EDELMANN. *Jahrb. Berg und Hüttenw. Sachsen* **100A,** 74–5(1926); *Mineralog. Abstracts* **3,** 472.—In a quartz-wolframite vein in the Sadisdorf Cu mine near Schmiedeberg were found a few cyan-blue to blue gray crystals with a pearly luster. Sp. gr. 2.39; H 3.5–4; monoclinic twinned on (100) with an orthorhombic habit, cleavage (010), strong pleochroism. The mineral, called *kolbeckite,* is difficultly sol. in acids and contains much Be with P_2O_5, SiO_2, little Al and Mg, traces of Cu, Fe and SO_3. It appears to be a phosphate or silico-phosphate of Be. J. F. SCHAIRER

A new platinum mineral in the Rustenburg norites. R. A. COOPER. *J. Chem. Met. Mining Soc. S. Africa* **28,** 281–3(1928).—The compd. secured from platiniferous norites was almost completely insol. in aqua regia and assayed: Pt 64.2, Pd 9.4, S 17.7, As 7.7%. The presence of Pd is probably due to the difficulty of making a clean sepn. The insol. Pt in the output from the Onverwacht dunite deposit is a sulfarsenide of the following compn.: Pt 59.3, S 3.7, As 36.9%. The new sulfarsenide possesses a more grayish steely color than sperrylite ($Pt\ As_2$) and is usually in irregular fragments or very complex cryst. forms with occasional elongated rectangular rods.

W. H. BOYNTON

Andorite from Felsobanya. S. KOCH. *Ann. Hist. Nat. Musei Nationalis Hungarici* **23,** 263–71, 271–2(1926); *Mineralog. Abstracts* **3,** 506; cf. *C. A.* **22,** 2903.

J. F. SCHAIRER

Barite deposits in the vicinity of Gado siding, Givelo district. F. E. KEEP. *S. Rhodesia Geol. Surv. Short Report* No. **22,** 7 pp.(1927); *Mineralog. Abstracts* **3,** 490.—Very pure deposits of $BaSO_4$ occur in felsitic schists in lenses parallel to the foliation. At least 100,000 tons of high-grade barite exist within a depth of 15 ft. from the outcrops. J. F. SCHAIRER

Anchi-stoichiometric types of biotite granite arranged according to their theoretical feldspar mixtures. PETER CHIRVINSKII. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **53,** 209–28(1926); cf. *C. A.* **20,** 1045.—C. has calcd. the chem. compn. of feldspars from available analyses of biotite granite and arranged a classification of these granites according to the compn. of their feldspars. J. F. SCHAIRER

The fine structure and physical behavior of brookite, and the change of state of the three natural forms of titania. ALFRED SCHRÖDER. *Z. Krist.* **67,** 485–542(1928).—A detailed discussion of data previously presented in brief form (cf. *C. A.* **22,** 2341). Additional data concerning variations in *n,* expansion and d. with change in temp. are included. Twenty-nine references are given. L. S. RAMSDELL

New investigations on the system: aluminum oxide–silicon oxide. WILHELM

EITEL. *Ber. deut. keram. Gesell.* **7,** 348–50(1926).—According to Bowen and Greig (*C. A.* **18,** 2587) mullite and sillimanite are similar in many properties but differed in compn. and thermal behavior. H. Mark (*C. A.* **21,** 3145) and P. Rosland, as a result of x-ray investigations, claim that mullite really consists of minute crystals of corundum in a fine threaded grating of sillimanite. From a mineralogical point of view the existence of mullite as an individual species could not be maintained. Just how the corundum and sillimanite are mixed is still a question but it is possible that the excess alumina is combined with the sillimanite in solid soln., or alumina in colloidal form may be entangled in the crystal structure of sillimanite. H. G. SCHURECHT

The brucite and hydromagnesite of a new deposit in the Urals. N. IGNATIEV. *Cr. Acad. Sciences de L'Urss* **1926,** 132–5; *Chem. Zentr.* **1927,** II, 797.—Brucite with hydromagnesite, calcite and serpentine were found in magnesite pieces at Satka in the Ural. The first mineral has the compn. 0.06 SiO_2, 0.21 Al_2O_3, 0.09 Fe_2O_3, 0.58 FeO, 66.71 MgO, 1.36 CaO, 2.95 CO_2 and 28.91 H_2O, and forms a compact aggregate with leafy texture, while the hydromagnesite covers the brucite in a crust-like form. The hardness of the brucite is 2.5 and d_{17} = 2.391. It forms uniaxial, optically positive platelets with ω = 1.5577 and ϵ = 1.5811. G. SCHWOCH

The structure of β-corundum. C. GOTTFRIED. *Fortschritte Mineral. Kryst Petrog.* **12,** 34–5(1928); cf. *C. A.* **22,** 2088.—A preliminary examn. by x-rays of β-corundum gave *n* 1.68, d. 3.30 and O at. vol. 17.25 cubic A. U. as against 1.768 and 14.05 for α-corundum, pointing to a closely packed arrangement for the latter and an open structure for the β-modification. The Laue diagram shows a hexagonal axis with 6 planes of symmetry. The unit cell has the dimensions a = 5.63, c = 22.63 A. U. (c/a = 4.02) and contains 12 mols. of Al_2O_3. J. F. SCHAIRER

Gem corundum. R. KLEMM AND G. O. WILD. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **53,** 266–70(1926).—A brief discussion of the coloring materials of the corundum gem stones. J. F. SCHAIRER

Etch and solution figures on corundum. M. SEEBACH. *Neues Jahrb. Min Abt. A, Beil.-Bd.* **54,** 420–43(1926).—Artificial corundum (polished spheres) was etched in fused $KHSO_4$ for different lengths of time. The indices of the solution forms are compared with those of the growth forms. J. F. SCHAIRER

Chemical analysis of the epsomite from the schists of the Zahořany horizon on the Letna. RUDOLF ZIRKOVSKÝ. *Časopis Narodniho Musea, Prague* **102,** 59–60(1928); *Mineralog. Abstracts* **3,** 546.—The schists near Prague are often coated with a white efflorescence, used for medicinal purposes in the 18th century. An analysis gave SO_3 28.10, MgO 13.63, CaO 0.52, insol. 15.58, H_2O [42.17] with traces of Fe, Al and alkalies. J. F. SCHAIRER

Some new curves for the determination of feldspars by the method of Fedorov. HENRI SIGG AND GEORGES FAVRE. *Bull. Soc. Vaud. Sci. Nat.* **51,** 341–80(1917); *Mineralog. Abstracts* **3,** 515.—From a revision of existing data on plagioclase twins the authors infer that the pericline law is not the only one in which the plane of association varies with the chem. compn. of the feldspar. This has been adversely criticized by Sabot (cf. following abstr.). J. F. SCHAIRER

The Fedorov method and its application to the determination of feldspars. R. SABOT. *Compt. rend. soc. phys. hist. nat. Genève* **35,** 72–6(1918); *Mineralog. Abstracts* **3,** 515.—The influence of a triclinic $KAlSi_3O_8$ on the optical consts. of the plagioclases was studied. The variation of the twin plane in Carlsbad and Esterel-Ala twins was detd. Fine twin-lamellae parallel to ($\bar{1}$10) and (110) were observed. In normal hemitropes no variation is found in the position of the twin plane. The explanation of these variations as due to vicinal faces (Sigg and Favre) is not accepted. J. F. SCHAIRER

Laue diagram of fluorite. HANS CLAUSEN. *Meddel. Dansk. geol. For.* **7,** 40 (1926); *Chem. Zentr.* **1927,** II, 1927.—The intensity relations of a Laue diagram of fluorite on (100) agreed with the structure found by Bragg. C. C. DAVIS

The identification of dumortierite as grains; dumortierite in Cornish granite. A. W. GROVES. *Mineralog. Mag.* **21,** 489–92(1928).—In the study of heavy mineral grains some confusion may arise between dumortierite and tourmaline, glaucophane, andalusite, sillimanite and lepidolite. The sign of elongation and character of pleochroism are important in making distinctions. Dumortierite was found in the sediments of southern England and in the granite of Land's End, Cornwall. W. F. H.

Glauconite from Lyssaja Gora at Saratov. P. PILIPENKO. *Wiss. Verhandl. Staatsuniv. Saratov* **5,** 255–65(1926); *Chem. Zentr.* **1927,** II, 1937.—The glauconite is obtained by elutriation of a chalk marl from Lyssaja Gora, of which it comprises about 45%. It contains 5.02–5.49% H_2O (above 110°). Treatment with concd

HCl forms quartz pseudomorphs. Analyses showed a compn. of $2.5R_2'O.R_2''O.2R_2'''.0.8SiO_2.4H_2O$, where R' = K, Na, H and Li, R'' = Ca and Mg and R''' = Al and Fe. C. C. DAVIS

A variety of gypsum from the island of Vulcano containing barium and strontium. G. CAROBBI. *Ann. R. Osservatorio Vesuviano* [3], **2**, 125–6(1925); *Mineralog. Abstracts* **3**, 551.—Among the abundant crusts in the "Grotta Piccola dell' Allume" on Vulcano, Lipari Islands are colorless crystals of gypsum which gave on analysis: SO_3 46.70, BaO 0.07, SrO trace, H_2O 20.68. C. suggests that $BaSO_4.2H_2O$ and $SrSO_4.2H_2O$ may exist in a very limited amt. in mixed crystals with $CaSO_4.2H_2O$. J. F. SCHAIRER

Hatchettine and valaite in the Silurian of Bohemia. JOSEF ŠPAČEK. *Sbornik prirodovedecky, Prague* **4**, 43–56(1927); *Mineralog. Abstracts* **3**, 547.—The hatchettine and valaite have been derived from naphtha which is still present in small amts. and is evidently of animal origin. Diabases near these beds often contain a kind of coal supposed to be "petroleum coke" and formed by the igneous intrusion into the Carbonaceous beds. J. F. SCHAIRER

Hypersthene-andesite from Nagyhegy. MARIA VENDL. *Ann. Hist.-Nat. Musei Nationalis Hungarici* **23**, 169–73, 173–7(1926); *Mineralog. Abstracts* **3**, 498.—The pyroxene-andesite contains porphyritic plagioclase and hypersthene. The latter is present as well formed crystals. In the groundmass of the rock consisting of plagioclase, apatite, magnetite, there are small cavities with minute tabular crystals of tridymite and prismatic crystals of amphibole. A chem. analysis of the rock is given. The SiO_2 (65.32%) is higher than in other Hungarian pyroxene-andesites and is near some of those from the Sierra Nevada in Calif. J. F. SCHAIRER

Two Bohemian minerals of the jarosite group. RUDOLF JIRKOVSKÝ. *Časopis Národního Musea, Prague* **101**, 151–5(1927); *Mineralog. Abstracts* **3**, 546.—An analysis of a yellow crust from Kopeč shows the highest degree of miscibility of the jarosite and alunite molecules (nearly 1:1) yet observed in this group. Natrojarosite occurs at Valdice near Kostalov. J. F. SCHAIRER

A new occurrence of kaolinite in Northumberland. S. J. TOMKEIEFF. *The Vasculum, Newcastle-upon-Tyne* **11**, 72–4(1925). **Occurrence and mode of origin of certain kaolinite-bearing nodules in the Coal Measures.** S. J. TOMKEIEFF. *Proc. Geol. Assoc. London* **38**, 518–47(1927); *Mineralog. Abstracts* **3**, 444.—Ironstone nodules in shale at Cow Gate have the cracks of the nodule filled with kaolinite and calcite. Chem. analysis after deduction of Fe_2O_3 and CO_2 gave SiO_2 46.89, Al_2O_3 39.30, H_2O 13.81. A detailed chem. and mineralog. study of the nodules and shale has been made and the author discusses the origin of the kaolinite and formation of concretions at length. J. F. SCHAIRER

Löllingite from the pegmatite of Dolni Bory. JOSEF VYSLOUŽIL. *Příroda, Brno* **21**, 81(1928); *Mineralog. Abstracts* **3**, 548.—An analysis of lollingite gave Fe 27.83, As 73.36, S 1.46, insol. 0.17, sum 100.82. J. F. SCHAIRER

Observations on magnetite, ilmenite, hematite and their relation to the system FeO-Fe_2O_3-TiO_2. PAUL RAMDOHR. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **54**, 320–79 (1926).—From a microscopic and chemical study of natural minerals some data were accumulated on the systems Fe_2O_3–Fe_3O_4, Fe_3O_4–$FeTiO_3$, $FeTiO_3$–Fe_2O_3, $FeTiO_3$–TiO_2, Fe_2O_3–TiO_2 and Fe_3O_4–TiO_2. Analyses of ilmenite are included. J. F. S.

Veins of magnetite in the Valle di Peio near Fucine, Trento. B. LOTTI. *Rass. min. met. ital.* **68**, 69–70(1928).—The cryst. schist which dominates the Peio valley is composed of gneiss, mica-schist, pegmatite, amphibolite, limestone and lime schist and is part of a granitic mass. In fracture cleavages of the limestone and schists are deposits of magnetite, pyrite and pyrrhotite in a matrix of quartz and ferrocalciferous silicates. C. C. DAVIS

Fluorite veins in the Black Forest. M. HENGLEIN. *Steinindustrie* **1927**, 54; *Chem. Zentr.* **1927**, II, 1938.—A description of fluorite veins in Kinzigtal, Ödsbachtal Hesselbachtal and near Grumbach. C. C. DAVIS

The structure of the phenacite–dioptase group. C. GOTTFRIED. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55**, 393–400(1926–7).—The elementary cell of phenacite has the dimensions a = 12.49, c = 8.26 A. U.; for willemite a = 14.14, c = 9.58 A. U.; for troostite a = 14.21, c = 9.62 A. U. An analysis of troostite is given. Dioptase gave the dimensions a = 14.66, c = 7.83 A. U., and is isomorphous with the other members of the phenacite group studied. J. F. SCHAIRER

The first occurrence of pisanite in Hungary. GABRIEL VAVRINECZ. *Magyar Chemiai Folyoirat* **32**, 88–95(1927); *Mineralog. Abstracts* **3**, 504; cf. *C. A.* **22**, 2126. J. F. SCHAIRER

Some properties of plagioclases. MARCEL GYSIN. *Compt. rend. soc. phys.*

hist. nat. Genève **39,** 70–3(1922); *Mineralog. Abstracts* **3,** 517.—G. has studied the variations in chem. compn. of plagioclase phenocrysts and microlites in different rocks. J. F. SCHAIRER

Pseudogaylussite. J. VAN BAREN. *Mededeelingen van het geologisch Instituut der Landbouwhoogeschool, Wageningen* No. **10,** 25 pp.(1926); *Mineralog. Abstracts* **3,** 485.—A detailed review of the literature on *pseudogaylussite* is given. Objects imbedded in clay from near Avenhorn consist of calcite rhombohedra with grains of glauconite, epidote, quartz and iron sulfide and diatoms. An analysis showed 93.25% $CaCO_3$. These objects are of concretionary origin. J. F. SCHAIRER

Analysis of pseudopite from Borostyankő. GABRIEL VAVRINECZ. *Magyar Chemiai Folyoirat* **33,** 185–7(1927); *Mineralog. Abstracts* **3,** 505.—Three analyses are given. J. F. SCHAIRER

Types of Hungarian rhyolite. ALADAR VENDL. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55,** 183–249(1926–7).—Analyses of rhyolites, rhyolite pitchstone, felsitic rhyolite, glassy rhyolite, perlite and obsidian are given. J. F. SCHAIRER

The optical properties of rinneite. C. W. CHENG. *Fortschritte Mineral. Kryst. Petrog.* **12,** 21(1927).—Optical data are recorded for rinneite. J. F. SCHAIRER

Sphalerite from Mantova near Chotěšov. FRANTIŠEK ULRICH AND VACLAV VESELY. *Věstnik Statniho Geol. Ustavu Československé Republiky* **3,** 32–5(1927); *Mineralog. Abstracts* **3,** 547.—An analysis of sphalerite from the Masaryk coal mine at Mantova yields the formula 9 ZnS.FeS, sp. gr. 4.03. J. F. SCHAIRER

New strontium mineral from the bauxite deposit in Tikhvin district, Russia. O. M. ANSHELES. *Mem. Soc. Russe Min.* [2], **56,** 53–60(1927)(English Summary); *Mineralog. Abstracts* **3,** 473.—A mineral named *tikhvinite* occurs as almond-shaped bodies, 5 mm. across, sp. gr. 3.32, n = 1.62, optically anisotropic, insol. in acids. Analysis gives formula $2SrO.3Al_2O_3.P_2O_5.SO_3.6$ or $7H_2O$. The mineral is near svanbergite and harttite in compn. J. F. SCHAIRER

Wiikite. LAURI LOKKA. *Bull. Comm. Geol. Finlande* No. **82,** 68 pp.(1928).—In 1895 Ramsay gave the name wiikite to the yellow variety of a "euxenit-like" mineral. L. has made a complete study of the occurrence, crystallography, chem. compn., phys. properties and radioactivity of *wiikite*. Complete analytical directions are given for the detn. of a mineral contg. Cb_2O_5, Ta_2O_5, TiO_2, SiO_2, ZrO_2, ThO_2, UO_2, Y_2O_3, Ce_2O_3, Al_2O_3, Fe_2O_3, FeO, MnO, PbO, MgO, CaO, S, H_2O. Complete analyses of wiikite from Hunttila, Lokansaari and Nuolainniemi are given. L. concludes that wiikite and samarskite are isomorphous. The age of the wiikite calcd. from the U, Th and Pb ratios varies from 401 to 2527 million years. The material from Nuolainniemi was found (microscopically) to consist of two different substances—much black opaque cryst. material and an isotropic colorless substance. To this mixt. L. gives the name *nuolaite*. Nuolaite is almost free from UO_2 but is rich in ThO_2. J. F. SCHAIRER

X-ray studies of zunyite. B. GOSSNER. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55,** 319–32(1926–7).—The elementary cell contains 6 molecules of $3SiO_2.3AlO(F,Cl).4AlO_2H.2AlO_3H_3$. a = 13.92 A. U. (mean value). Rotating crystal, powder and Laue methods were used. J. F. SCHAIRER

Study of feldspar twins by the Fedorov method. ELVIRA CARRASCO. *Bull. Soc. Vaud. Sci. Nat.* **52,** 483–564(1920); *Mineralog. Abstracts* **3,** 516.—Tabulated measurements made on 37 feldspars in rocks are given. Departures from Michel Levy's curve connecting the optic axial angle with the chem. compn. of plagioclase are found. J. F. SCHAIRER

Manebach, Ala and complex twins: study of extinction angles on oriented sections. HENRI SIGG AND ELVIRA CARRASCO. *Bull. Soc. Vaud. Sci. Nat.* **52,** 219–23(1919); *Mineralog. Abstracts* **3,** 516.—Data are given in four tables for the extinction in oriented sections of 7 plagioclases of known chem. compn. and of the corresponding individuals in various twins. J. F. SCHAIRER

Magmatic reactions. E. LEHMANN. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **54,** 165–294(1926).—A discussion of chem. reactions during differentiation, with many examples and equations showing the chem. changes. J. F. SCHAIRER

The structure of aluminum silicates of the type Al_2SiO_5 and of pseudobrookite. H. MARK AND P. ROSBAUD. *Neues Jahrb. Min. Abt. A, Beil-Bd.* **54,** 127–64(1926).—By the rotating crystal x-ray method the following data were obtained: cyanite a 7.18, b 8.00, c 5.55 A. U.; andalusite a = 7.90, b 7.90, c 5.5 A. U.; sillimanite a 7.25, b 7.65, c 5.88 A. U.; artificial fibrous mullite c = 2.94 A. U. (half that of sillimanite). From the data on mullite the compn. must be $2Al_2SiO_5$ or Al_2SiO_5 (not $3Al_2O_3.2SiO_2$). Pseudobrookite gave a 9.78, b 9.80, c 3.65 A. U. with 4 mols. of Fe_2TiO_5. It is isomorphous with andalusite. J. F. SCHAIRER

The necessity of a physicochemical study of the reaction: $2CaCO_3 + MgSO_4 \rightleftharpoons CaCO_3.MgCO_3 + CaSO_4$. B. P. Krotov. Univ. of Kassan. *Ann. inst. anal. phys.-chim.* (*Leningrad*) **3**, 662–82; *Chem. Zentr.* **1927**, II, 2659–60.—The Haidinger reaction: $2CaCO_3 + MgSO_4 \rightleftharpoons CaCO_3.MgCO_3 + CaSO_4$, is probably capable of explaining numerous geologic phenomena. Thus dolomites are probably formed by this reaction, the equil. being displaced toward the right because $CaSO_4$ is insol. in concd. $MgSO_4$ solns. On evapn. of sea water the high concn. of $MgSO_4$ is reached only when the soln. is already satd. with NaCl. It was therefore to be expected that dolomites would ordinarily contain NaCl as an impurity, a supposition that was verified by numerous tests. The insol. $CaSO_4$ formed at the same time as the dolomite likewise was found very frequently. This assocn. would make possible the reverse transformation to $CaCO_3$ and $MgSO_4$ under the influence of ground water contg. no $MgSO_4$. That dolomite and gypsum (or anhydrite) can nevertheless exist together is probably to be explained by the fact that ground water contains considerable NaCl, and NaCl inhibits, according to Haidinger, the course of the reaction from right to left. The Haidinger reaction also plays a part in the drying up of seas contg. $MgSO_4$, when the soil consists of limestone. In this way may also be explained the fact that the Stassfurt deposits contain less $MgSO_4$ than that which should correspond to their origin from sea water. C. C. Davis

Scientific expedition to Karabugaz in the years 1921–1923. N. I. Podkopaev. *Ann. inst. anal. phys.-chim.* (*Leningrad*) **3**, No. 2, 683–702(1927); cf. *C. A.* **21**, 3862.—In addn. to metereological observations in the Karabugaz Sound region, evidence is presented that the deposition of Glauber salt in Karabugaz is of periodic character. The salt is deposited during the 4 winter months (Nov. 20, 1922 to Feb. 15, 1923), while the temp. of the water is 5.5–6.0° and is dissolved during the remainder of the year. G. B. Kistiakowsky.

New theories of the formation of coal. W. Fuchs. *Brennstoff-Chem.* **9**, 153–6 (1928).—A review of recent work of Bergius (*C. A.* **22**, 1027) and that of McKenzie Taylor (*C. A.* **21**, 4049). According to Bergius all plant compds. contributed to the formation of coal since he was able to synthesize coal-like substances from all these substances by heating to 340° with H_2O under pressure. F. does not agree that Bergius' synthetic coals have been shown similar to natural coals. Taylor's work indicates that for a number of cases coalification could have resulted from anaerobic decay of plant materials, a cover impervious to gases being assumed formed by base exchange—Na of NaCl with Al of the clay cover. This may explain the first coalification stages in some cases, but not all coal overburdens are of such a nature as to favor the base exchange phenomenon. J. D. Davis

Investigation of the microbiology of coals as they occur in the coal beds. R. Lieske and E. Hofmann. *Brennstoff-Chem.* **9**, 174–8(1928). J. D. Davis

The chemical composition of peat. I. Chemical nature of organic complexes in peat and methods of analysis. Selman A. Waksman and Kenneth R. Stevens. N. J. Agr. Expt. Sta. *Soil Science* **26**, 113–37(1928).—A method of proximate analysis which accounts for about 90% of the peat is suggested. By the method given different kinds of peat can be differentiated. Low-moor and high-moor peats on the dry basis contained ether-sol. matter 0.43, 4.34; H_2O-sol. 1.71, 1.61; C_2H_5OH-sol. 1.94, 3.40; hemicellulose 11.03, 15.76; pentosan 2.52, 3.60; celluloses 0, 12.35; lignin 44.81, 44.19; crude protein 20.97, 4.94 and ash 13.02 and 1.82%, resp. Similar analyses of peat-forming materials are tabulated. These include results for *Carex, Cladium, Hypnum, Sphagnum, Pinus Strobus* needles and oak leaves. In low-moor peat true cellulose has completely decomposed. The protein content is higher than in the original plant materials because of the synthesizing activity of microörganisms. In high-moor peat much cellulose remains. Waxes have accumulated in high-moor but not in low-moor peat. Thirty-seven references are appended. A. L. Mehring

Notes on the theory of petroleum formation. Conclusions to be drawn from the composition of Cheremchovskii boghead coal. G. Stadnikov and E. Ivanovskii. *Brennstoff-Chem.* **9**, 245–8(1928). The theory most generally held is that the material from which petroleum was formed consisted mainly of oil algae. Boghead coals were most probably formed from the same sort of material; accordingly their primary tars ought to possess petroleum characteristics. The authors subjected such a tar to thorough examn., sepg. the main classes of compds. present. Compds. were mainly unsatd. and satd. hydrocarbons, the latter being paraffins. No cyclic compds. were found and only 1.88% bases and 1.67% tar acids. Low tar acids indicate little humic matter in the coal. One can conclude, therefore, that the cellulose and albumin of the algae from which the coal originated have entirely disappeared and that the coal consists

of polymerization products of the fats and waxes. The compds. in the tar are very similar to those found in petroleum. The result is in agreement with the Fischer-Schrader lignin theory of coal formation in that this involves complete elimination of cellulose and formation of coal humus from lignin. J. D. DAVIS

Notes on the theory of petroleum formation. Conclusions drawn from the composition of tar from Cheremchovskii boghead coal. G. STADNIKOV AND E. IVANOVSKII. *Brennstoff-Chem.* **9,** 261–4(1928); cf. preceding abstr.—The similarity of thermal decompn. products of fats to boghead coal tars has been noted. The authors decompose linoleic acid at 400° in H_2 using Fe supported on asbestos as a catalyst and examg. the products. The reaction proceeds in 2 directions: (1) formation of CO_2 and satd. hydrocarbons and (2) formation of CO, H_2O and unsatd. hydrocarbons. Oxidation of the unsatd. hydrocarbons of both the tar and products from linoleic acid with $KMnO_4$ yielded fatty acids and only a small amt. of succinic acid; glutaric and adipic acids were not formed. The hydrocarbons therefore belonged to the aliphatic and not the aromatic series. Paraffins and unsatd. hydrocarbons were purified by distn. with steam, fractionated and analyzed. In every respect compds. of the tar showed similarity to those obtained from the linoleic acid and to those obtained by Engler (*Ber.* **30,** 2367(1897)) by decompn. of fatty acids. In the first decompn stage of boghead coal fatty acids are probably formed and subsequently decompd. The coal itself is to be looked upon as a mixt. of polymerized fatty acids. J. D. DAVIS

Cholesterol as the mother substance of petroleum. II. N. D. ZELINSKII AND K. P. LAVROVSKII. Univ of Moscow. *Ber.* **61B,** 1291–3(1928); cf. *C. A.* **22,** 89.—From 655 g. cholesterol (I) treated with $AlCl_3$ were obtained 405 g. of a petroleum-like product, d_4^{20} 0.8539, of which about 190 g. distd. over with steam (in the distn. the liberation of dissolved gaseous hydrocarbons was observed). The light oil, treated with concd. H_2SO_4, washed well and dried, yielded 2 fractions: 120 g., b. 35–150° and 63 g., b. 150–250°. These were further fractionated and the individual fractions subjected to dehydrogenation catalysis to det. the chem. nature of their constituents. The results of this and the earlier work show that the artificial petroleum prepd. from I is a complex mixt. of hydrocarbons contg. only very small quantities of aromatic derivs. and consisting chiefly of paraffins and cycloparaffins; among the latter, the derivs. of cyclohexane predominate. They are easily dehydrogenated and after removal of the resulting aromatic hydrocarbons the residues consist either exclusively of compds. C_nH_{2n+2} or of mixts. of these with cycloparaffins (naphthenes) with no hexahydroaromatic character. **Addendum.** N. D. ZELINSKII. *Ibid* 1293–4.—Brief reply to Steinkopf (*C. A.* **22,** 1163). C. A R.

Indications of petroleum in Sundgau (Upper Alsace). JEAN JUNG. École nat. superieure petrole comb. liquides. *Ann. office nat. comb. liquides* **3,** 165–89(1928)—A study of the geology of the region (described in detail) and signs of petroleum at Sentheim and Hirtzbach indicate that the existence of petroleum is possible in Sundgau, which is a part of the basin west of Mulhouse between the Vosges and Jura mountains. R. E. SCHAAD

Mirabilite as a product of the activity of Vesuvius. F. ZAMBONINI. *Ann. R. Osservatorio Vesuviano* [3], **2,** 117–9(1925); *Mineralog. Abstracts* **3,** 550.—Small stalactites of a saline incrustation consist mainly of mirabilite with some aphthitalite. The existence of *exanthalite* is doubtful and $Na_2SO_4.2H_2O$ could not be obtained artificially. *Lecontite* is probably a mixt. of the double salts $NaKSO_4.2H_2O$ and $NaNH_4SO_4.2H_2O$ rather than $(Na,K,NH_4)_2SO_4.2H_2O$. The mirabilite has no doubt been produced by the secondary hydration of thenardite and "exanthalite" is probably a mixt. of the two. J. F. SCHAIRER

The presence of soluble compounds of selenium and tellurium as products of the activity of Vesuvius. F. ZAMBONINI AND L. CONIGLIO. *Ann. R. Osservatorio Vesuviano* [3], **2,** 3–6(1925); *Mineralog. Abstracts* **3,** 550.—A short review of the literature on occurrences of Se and Te in volcanic products. A yellow crust (1925) consisted of opal, S, chlorides and sulfates of alkali metals with Fe, Pb, Cu and Ca. The aqueous soln. contained Se 1.25% of the incrustation and Te 0.04%. J. F. SCHAIRER

New observations on the lavas of the islands of Marquesas and Tubuai, Southern Polynesia. A. LACROIX. *Compt. rend.* **187,** 365–9(1928).—Chem. analyses by Raoult of 21 samples of these lavas are reported. These include 6 trachytes, 9 basalts, 2 phonolites, 2 andesinic andesites, a latite and an ankramite. **New observations on the lavas of the leeward islands of the Society Archipelago.** *Ibid* 397–401.—These lavas are discussed on the basis of chem. analyses of 14 samples by Raoult, comprising 6 basalts, 3 gabbros, 2 pegmatoids and 1 each of latite, doreite and labradoric andesite. L. W. RIGGS

The pegmatoids of volcanic rocks with basaltic facies. A. LACROIX. *Compt. rend.* **187,** 321–6(1928).—Nine analyses by Raoult are reported for samples of andesinic basalt and pegmatoids from Beaulieu, France, Bora-Bora Tahitian Archipelago and Weit'chang, Hoa-mou-keow, North China. These analyses are discussed from the lithologic and genetic points of view. L. W. RIGGS

Note on the alkali lavas of Mount Nimrud, Armenia. G. T. PRIOR. *Mineralog. Mag.* **21,** 485–8(1928).—The alkali rocks of Mount Nimrud show strong similarities to those of the Rift Valley region in East Africa. They vary from riebeckite-rhyolite containing free quartz to more basic types with olivine. Anorthoclase is the prevailing feldspar. Other minerals present include aegirine, riebeckite and cossyrite. Chem. analyses are given of comendite, kenyte and trachyandesite. W. F. HUNT

Mannum granite. B. F. GOODE. *Trans. Proc. Roy. Soc. S. Australia* **51,** 126–8 (1927).—This granite from Section 156, Hundred of Younghusband, has the compn: SiO_2 70.77, Al_2O_3 13.69, Fe_2O_3 1.97, FeO 0.97, MgO 0.34, CaO 0.94, Na_2O 3.70, K_2O 5.68, TiO_2 0.72, MnO 0.28, P_2O_5 0.11, FeS_2 0.17, H_2O—0.45, H_2O + 0.36, sum 100.15%; sp. gr. 2.66. Microscopic measurements by the Rosiwal method gave the mineral compn.: quartz 25.99, orthoclase 34.09, plagioclase 30.75, biotite 3.13, Fe ores 3.33, sphene 1.86, apatite 0.62, sum 99.77%. L. W. RIGGS

Bismuth mines in Bolivia. FRIEDRICH AHLFELD. *Metall Erz* **24,** 353–6; *Chem. Zentr.* **1927,** II, 1559.—The primary Bi ores are Bi glance and pure Bi. Bi ocher is the most important of the secondary ores. The deposits are worked unsystematically, since the world requirements of Bi are so small. Ore contg. less than 2% Bi is of no value for working. The ore is not dressed, but only sepd. by hand. C. C. DAVIS

[From the gold mines of Jilové.] JINDŘICH L. BARVIR. Privately printed, Prague, **1927,** 120 pp.; *Mineralog. Abstracts* **3,** 491.—The petrogenetic and metallogenetic features of the ancient Au mining district of Jilové are described. Of special interest (p. 50) is the report on expts. on the pptn. of Au by interaction of solns. of $AuCl_3$ on pyrite associated with chlorite. More Au was deposited on the chlorite than on the pyrite. J. F. SCHAIRER

The copper deposits of Belgian Congo. ENRIQUE FALCAT. *Quim. ind.* **5,** 140–3 (1928). MARY JACOBSEN

Microscopic-mineralogical studies of the copper sulfide ores of the Sieglünd spathic iron deposits. RÜDIGER RÜCKERT. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **53,** 185–96 (1926).—Polished sections of Cu ores were studied. An analysis of *sychnodymite* is included. By means of the microscopic studies the chem. alteration of the ores by hydrothermal solns. is followed. J. F. SCHAIRER

Micrographs of the iron ore minerals of basalt. H. W. LINDLEY. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **53,** 323–60(1926).—A detailed description of the Fe ores occurring in basalt of Vogelsberg. From published analyses the course of chem. differentiation is traced. J. F. SCHAIRER

The iron ore deposits of the Oberharz diabase ranges and their relation to the Brocken-contact. PAUL RAMDOHR. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55,** 333–92 (1926–7).—Analyses of fayalite, cordierite, fayalite-spinel-cordierite hornfels and mica peridotite are given. J. F. SCHAIRER

The iron deposits of the Union of South Africa. PERCY A. WAGNER. *Mem. Geol. Surv. S. Africa* No. **26,** 264(1928); *Mineralog. Abstracts* **3,** 490.—This memoir includes the history, classification, discussion of origin and description of the iron ores and ore reserves of S. Africa. J. F. SCHAIRER

Formation relations of the iron ore deposits from the system ferric chloride–water. ERNST STIRNEMANN. *Neues Jahrb Min. Abt. A, Beil.-Bd.* **53,** 59–94(1926).—A brief summary is given of the literature on the occurrence of $FeCl_3$ as one of the volatile components of magmas. The equil. data on the system $FeCl_3$–water (cf. *C. A.* **21,** 3572) are applied to the Fe ore deposits. A description is given of the methods used in making artificial hematite and magnetite. The phys.-chem. data are applied to the Fe ore deposits of Braunfels, Elba, Oslo and Clifton-Morenci. J. F. SCHAIRER

The iron and manganese ore deposits near Oberrosbach, Oberhessen province. W. WITTE. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **53,** 271–322(1926).—Analyses of ore and rocks inclosing the ore are included. J. F. SCHAIRER

The occurrence of manganese in the state of Minas Geraes, Brazil. M. SCHWERBER. *Metall Erz* **24,** 329–31; *Chem. Zentr.* **1927,** II, 1461–2.—Manganese ores occur in the form of pyrolusite in veins and boulder deposits. The latter are at present of no significance. The Mn content of the former is quite const. at 48–50%. The veins

which are imbedded in Fe-contg. argillite are mined mostly in open works, some also in deeper mines. J. S. REICHERT

Manganese ore deposits in Tschiaturi (Caucasus). W. DE LA SAUCE. *Abh. prakt. geol. Bergwirtschaftslehre* **8**, 90(1926); *Neues Jahrb. Mineral., Geol., Paläont., Abt. B* **1927**, II, 207–8; *Chem. Zentr.* **1927**, II, 2541.—In 1913 the deposits yielded over 0.5 of the world requirements, and are adequate for the same needs for another 60 yrs. The ore is predominantly MnO_2 and is easily obtained. Its origin is attributed to weathering and soln. of the granite massiv of Suram. C. C. DAVIS

Nickel. N. A. SHADLUN. *Commission for the study of the natural products of Russia, Russ. Acad. Sci.* **4**, No. 5, 7(1923); *Mineralog. Abstracts* **3**, 492.—Special reference is made to the Novo-Cheremshansky mine. The clayey Ni ores occur in polianite, siderite, limonite and lignite. The last contains C 42% and ash 6–7%. The ash contains 3–15% Ni and 40% $CaSO_4$. This type of ore is named *kerzinite*. The Ni-bearing polianite ore (Ni 4–7%) has been derived from serpentine, which as dunite was intruded as veins in marble. The richer ore (Ni 12–15%) lies in contact with the marble. J. F. SCHAIRER

The optical properties, density and changes of state of zircon. WILHELM F. EPPLER. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55**, 401–87(1926–7).—See *C. A.* **22**, 3823. J. F. SCHAIRER

Iodine in nature. XII. Geochemistry of iodine (3). The atmophile character of iodine. TH. VON FELLENBERG. *Mitt. Lebensm. Hyg.* **19**, 43–8(1928); *Biochem. Z.* **193**, 384–9(1928); cf. *C. A.* **17**, 2717; **21**, 3034, 3586.—Gases from mofette, springs and rocky walls contained I. Gases from the mofette tested were 40 times richer in I than gas from springs. The geological origin of the I impregnation of volcanic gases is discussed. L. W. RIGGS

Iodine in phosphate deposits. ERNST WILKE-DÖRFURT, JULIUS BECK AND GASTON PLEPP. Stuttgart tech. Hochschule *Z. anorg. allgem. Chem.* **172**, 344–52(1928).—Apatite is known to contain F and Cl and I may be expected to be present. Artificial iodo-apatites were made by fusing tricalcum phosphate and KI at 1420° and the product gave 0.09%; in another case it gave 0.25%. As an iodopatite should contain about 20% I, these were not useful indications of its existence. Norwegian and Canadian (Renfrew Cities) apatite was analyzed and a very small I content was found. Fellenberg also records very low values for I in apatite. Conclusion: I cannot be combined with apatite in phosphate deposits. Differences in I content are explained by climatic conservation or aq. extn. and where the I content is high this is assumed to be org. in origin. The method used for the detn. of the I is given. A table of I content is given for 25 apatites from different sources; the highest appears from Limberg (280 mg./kg.). S. L. B. ETHERTON

Meteoric falls in France and her colonies preserved in the national natural history museum, with remarks on the classification of meteorites. ALBERT LACROIX. *Bull. Mus. Nat. Paris* **33**, 411–55(1927); *Mineralog. Abstracts* **3**, 534.—Regarding meteorites as igneous rocks, the following classification is proposed. I. Sporadosiderites (arolites). 1. Magnesio-calcic group (*a*) feldspathic; (*b*) non-feldspathic. 2. Magnesian group (*a*) peridotitic; (*b*) pyroxeno-peridotic; (*c*) pyroxenic. II. Syssiderites (lithosiderites). 1. Magnesian group (*a*) peridotitic; (*b*) pyroxeno-peridotic; (*c*) pyroxenic. 2. Magnesio-calcic group. III. Holosiderites. (*a*) Mionickeliferous; (*b*) Plionickeliferous; (*c*) Nickelic. J. F. SCHAIRER

Morphological and structural relations of meteoric irons in connection with their origin. J. LEONHARDT. *Fortschritte Mineral. Kryst. Petrog.* **12**, 52–5(1927).—*Kamacite* from various meteoric irons was examined by the powder and rotating-crystal x-ray methods. It shows a body-centered lattice with the edge a = 2.84 A. U. Laue photographs show that they fall into two groups: (1) with diffused spots representing paramorphs after α-iron; (2) showing normal spots representing single homogeneous crystals due to recrystallization and slower cooling. Formulas are given for calculating the orientation of sections from the angles of the Widmanstätten figures and for the orientation of Laue photographs. J. F. SCHAIRER

The structure of iron meteorites following the δ–γ-inversion of iron. RUDOLF VOGEL. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **53**, 134–48(1926); cf. *C. A.* **19**, 2009. J. F. SCHAIRER

The meteoric iron from Savik near Cape York, North-Greenland. O. B. BÖGGILD. *Meddel. om Grönland* **74**, 11–30(1927); *Mineralog. Abstracts* **3**, 535.—An analysis of a portion of the Cape York meteoric iron gave Ni 7.25, S 0.022, P 0.166, Cr trace, Si, C, Co, Cu nil., sp. gr. 7.91. Nodules and some streaks of troilite (0.65%) and small amts. of chromite and rhabdite are present. J. F. SCHAIRER

Mineral statistics. ANON. *Mineral Ind.* **36,** 688–748(1927).—Tables of production and trade for the principal countries of the world. A. B.

Outline of the history and present status of chemistry in the Institute of Mines. N. STEPANOV. *Ann. inst. anal. phys-chim.* (*Leningrad*) **3,** 510–24; *Chem. Zentr.* **1927,** II, 2641.—Deals with the Institute of Mines at Leningrad, founded in 1774. C. C. DAVIS

Annual report on the mineral resources of U. S. S. R. during the fiscal year 1925–6. *Leningrad* (*Geol. Committee*) Vol. **1,** 804(1927); *Mineralog. Abstracts* **3,** 492.—This volume with title-page, editorial note, contents, summary and index given in Russian and English is analogous to American publications such as "Mineral Resources of the U. S." All the metallic and non-metallic minerals of economic importance are reported. J. F. SCHAIRER

The geology and mineral industry of Western Australia. A. G. MAITLAND AND A. MONTGOMERY. *Bull. Geol. Survey W. Australia* No. **89,** 119(1924).—The principal mineral products of greatest importance in W. Australia are Au, Ag, coal, Sn, Cu, Pb and phosphates. Magnesite, salt, alunite, gypsum and mineral fertilizers are also produced. Data on production and occurrence of ores are given. Two analyses of glauconitic sandstone and marl mined at Gingin for the extraction of potash salts are given. A map showing the chief localities at which useful minerals are found is included. J. F. SCHAIRER

The mineralogy and petrography of the Rhön. F. HEIDE. Univ. Göttingen. *Chem. Erde* **3,** 91–7; *Chem. Zentr.* **1927,** II, 2659.—The montmorillonite of Rupsroth (Rhön) occurs in a very pure state in veins. The intense raspberry-red to white material which has a matted structure has a mean *n* value of 1.545 ± 0.006. X-ray examn. showed the same interferences as those of nakrite, with a diffuse blackening of probably amorphous substances which may consist of a mixt. of kaolin silicate with a gel. Analyses also indicate this compn. The investigation points to montmorillonite as possibly a very fine dispersion of Al_2O_3-SiO_2 gel particles in a kaolin network. Its occurrence in the Rhön region is attributed to deposition from aq. residues of phonolite magma. C. C. DAVIS

Geological and petrographic studies of the Kainuu region. HEIKKI VÄYRYNEN. *Bull. comm. géol. Finlande* No. **78,** 127(1928).—Analyses of leptite, sericite schist, gabbro-metabasite, amphibole from a metabasite, greenstone, amphibole from a greenstone, quartz keratophyre, phyllite-mica schist, carbonaceous phyllite and black schists are given. J. F. SCHAIRER

Petrography and geology of the Kaiserstuhl mountains in Breisgau. J. SOELLNER. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55,** 299–318(1926–7).—Analyses of essexite gabbro, theralite gabbro, monzonite, theralitic ijolite, dolerite and anamesite are given. J. F. SCHAIRER

Petrographic notes on tonalite from the Palmer District and biotite-norite from South Black Hill. A. R. ALDERMAN. *Trans. Proc. Roy. Soc. S. Australia* **51,** 20–3 (1927).—Tonalite from Section 380, Hundred of Finnis, Sturt Co., gave on analysis: SiO_2 63.88, Al_2O_3 16.37, Fe_2O_3 1.99, FeO 2.96, MgO 2.24, CaO 5.18, Na_2O 3.66, K_2O 1.61, TiO_2 0.86, P_2O_5 0.23, MnO 0.07, H_2O (combined) 0.45, H_2O (hygroscopic) 0.21, sum 99.71%; sp. gr. 2.792. Biotite-norite from Section 240, Hundred of Ridley, at South Black Hill gave: SiO_2 53.37, Al_2O_3 14.25, Fe_2O_3 2.55, FeO 7.44, MgO 5.04, CaO 8.87, Na_2O 2.50, K_2O 2.96, TiO_2 1.70, MnO 0.15, P_2O_5 1.24, H_2O (combined) 0.19, H_2O (hygroscopic) 0.22, sum 100.48%; sp. gr. 3.128. The results of the microscopical examn. of the rocks are reported. L. W. RIGGS

Plaffeiite, the fossil resin of the Flysch of Plaffeien. A. TSCHIRCH AND KATO. *Mitt Naturfor. Gesell. Bern* **1925,** 13–19; *Mineralog Abstracts* **3,** 475.—An amber-yellow resin occurs as fragments in nests and bands in the Flysch at Plaffeien, Switzerland. It is brittle, m. 211° and differs from all other fossil resins in chem. characters. Thirteen different resins (m. 60–284°) were extd. by solvents. Analyses of some of these resins are given. J. F. SCHAIRER

Unknown hydrosilicate-gel from the Rac quarry near Székes-Fejérvár. JÁNOS ERDÉLYI. *Magyar Chemiai Folyoirat* **33,** 133–5(1927); *Mineralog. Abstracts* **3,** 505.—A granite is coated with a soft pinguite-like decompn. product with a grass-green color. It was sol. in concd. HCl. An analysis is given. J. F. SCHAIRER

The auriferous lodes of the Gibraltar district, Coolgardie goldfield. F. R. FELDTMANN. *Bull. Geol. Survey W. Australia* No. **91,** 29(1925).—The lodes characteristic of the Gibraltar district consist of bands of schist with numerous quartz stringers and lenses of quartz. In the oxidized zone chloropal and halloysite occur and are accompanied by the richer ore. The ore bodies are low grade and the Au is erratic.

The Au came from the same magma as the pegmatities of the region but was deposited subsequent to their intrusion. J. F. SCHAIRER

The rock-making alkali hornblendes. W. KUNITZ. *Fortschritte Mineral. Kryst. Petrog.* **12,** 49–50(1927); cf. *C. A.* **22,** 2342.—A brief discussion of isomorphism in the alkali hornblende series. J. F. SCHAIRER

Crystallophyllitic rocks of Mayombe, French equatorial Africa. V. BABET. *Compt. rend.* **187,** 348–50(1928).—These rocks along the line of the "Congo-Ocean" railroad are classified as feldspathic with gneissic aspect, and nonfeldspathic. Analyses by Raoult are reported for albitic gneiss with sericite, albitic gneiss with 2 micas, chlorite-epidote-bearing mica schist, calciferous mica schist with epidote, epidotite and micaceous calciferous epidotite. L. W. RIGGS

The geological formation of clay. J. FISCHER. *Tonind.-Ztg.* **52,** 1231–3, 1272–3 (1928).—F. accepts the view that clay was formed by the action of CO_2-water on silicates which decomposed the rocks and dissolved the alkalies and alkali silicates. H. G. SCHURECHT

Augites from the rocks of the Euganean Hills. M. STARK. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **55,** 1–35(1926–7).—Optical data are given for various augites. J. F. SCHAIRER

Granodioritic mixed rocks of the Friedeberg intrusive mass. F. K. DRESCHEN. *Neues Jahrb. Min. Abt. A, Beil.-Bd.* **54,** 243–91(1926).—Analyses of aplite, granite gneiss, quartz-biotite gneiss, plagioclase-biotite gneiss, dioritic inclusions and granodiorite are included. Diagrams are given showing the relation of the chem. compn. of the different rocks. J. F. SCHAIRER

Rocks from Peter I Island, West Antarctic. OLAF A. BROCH. *Avhandl. Norske Vidensk.-Acad. Oslo, Mat.-Naturv. Kl.,* No. 9, 41(1927); *Mineralog. Abstracts* **3,** 500.—A detailed petrographic description is given of pebbles dredged from a depth of 6–7 fathoms close to the shore of Peter I Island. Four analyses of these rocks are included. J. F. SCHAIRER

Rocks of the Viborg-Rapakivi granite. WALTER WAHL. *Fennia (Bull. Soc. Geogr. Finland)* **45,** No. 20, 127(1925); *Mineralog. Abstracts* **3,** 499.—Petrographic. The mica of the Rapakivi-granite is a ferroferri-mica called *monrepite,* $KH_2Fe''Fe'''(SiO_4)_3$ J. F SCHAIRER

A custerite-bearing contact rock from California. C. E. TILLEY. *Geol. Mag.* **65,** 371–2(1928).—A rock from Crestmore, Calif., was found to contain vesuvianite, custerite, monticellite and calcite. New data on the optical properties of *custerite* $[Ca(F,OH)]_2SiO_3$, show that the mineral is monoclinic, optically +, Z being approx. normal to the twinning lamellas and the obtuse bisectrix emerges from sections cut normal to the lamellas. $\alpha = 1.588$, $\gamma = 1.600$. The occurrence of these rare minerals is a consequence of incomplete equil. during metamorphism. J. F. SCHAIRER

Fresh-water lime-manganese rocks and lime-magnesia fresh-waters. H. KLÄHN. *Chem. Erde* **3,** 453–587(1928); cf. *C. A.* **21,** 3864.—A detailed account of travertine deposits (fresh-water limestones and dolomites), with a discussion of the conditions for their formation and the compn. of the waters from which they are deposited. B. C. A.

Chemistry of the eruptive rocks of Gleichenberg, Steiermark. A. MARCHET. *Fortschritte Mineral. Kryst. Petrog.* **12,** 56–7(1927).—A brief summary of the chemical changes and rock types of the region. J. F. SCHAIRER

Chemical and petrographical investigations of the Kiev marl or spondylustone. Its homologs among recent marine formations. V. CHIRVINSKII. *Bull. sect. Ukraine Comité Geol.* **1926,** No. 8, 1–39; *Chem. Zentr.* **1927,** II, 1938.—The marl is very widely distributed, is of the lower Tertiary, and contains 48.76–100% clay, 0.–56.22% $CaCO_3$ and quartz, glauconite, pyrite, gypsum and other minerals. The marl is similar to blue ocean mud. C. C. DAVIS

"Cone-in-cone" marl. G. LINCK AND W. NOLL. *Chem. Erde* **3,** 699–721(1928).—A discussion of "cone-in-cone" structure in marls, including "nail limestone," with descriptions of material from Thuringia and Romania. Analyses show that $CaCO_3$ is the main constituent, with considerable and variable amts. of clayey matter and free SiO_2. The structure is attributed to the crystn. of a $CaCO_3$ gel in the presence of much foreign matter. Comparisons are made with a similar structure in fibrous celestite pseudomorphous after gypsum from Jena. B. C. A.

A biotite-scapolite schist from Petrov near Kunstat. J. ŠTĚPANEK. *Časopis Moravskeho Zemskeho Musea, Brno* **25,** 202–13(1927); *Mineralog. Abstracts* **3,** 548.—The scapolite occurs as porphyroblasts in a biotite schist. Approximate compn. 70% carbonate meionite with 30% chloride and oxide-marialite. J. F. SCHAIRER

Pipes in the coast sandstone of Syria. ALFRED ELY DAY. *Geol. Mag.* **65**, 412–5 (1928).—Analyses of sandstone, beach sand, dune sands and red sands are given. J. F. SCHAIRER

Comparative study of the weathering of rocks under different climatic conditions. E. BLANCK AND A. RIESER. *Chem. Erde* **3**, 437–52(1928).—Fragments of sandstone and of limestone were exposed to the weather during a period of 5 years at Göttingen and on the summit of the Brocken (1142 m.), where, owing to the difference in altitude, there are marked differences in the temp., rainfall and humidity. Detailed analyses of the rocks and of the portions extd. by HCl, both before and after the expt., showed no appreciable differences in compn. B. C. A.

Soils (and rock weathering) in Spitzbergen. E. BLANCK, A. RIESER AND H. MORTENSEN. *Chem. Erde* **3**, 588–698(1928).—A study of rock weathering under arctic conditions. Numerous detailed analyses are given of various rocks (sandstone, quartzite, clay-slate, phyllite, diabase and calcareous shale) and of their disintegration products, including soils and muds; analyses are also given of the portions extd. by HCl and by H_2SO_4 from the débris. Chem. action in weathering is here retarded owing to deficient water circulation, and the action of frost is of more importance in breaking down the rocks. B. C. A.

Chert deposits in Ecuador, South America. GEORGE SHEPPARD. *Geol. Mag.* **65**, 343–53(1928).—Analyses of shale and chert are included. Two classes of cherts are found in the region: primary chert, deposited from solution as a direct result of proximity to igneous intrusions and a secondary chert, derived from Tertiary shales which have become completely silicified. J. F. SCHAIRER

The miocene soils between the Senio and Sillaro valleys. P. PRINCIPI. *Atti accad. Lincei* [6], **7**, 579–86(1928).—The geology and mineralogy are described in detail. C. C. DAVIS

Red soils of Cochin China. V. AGAFONOV. *Compt. rend.* **187**, 428–31(1928).—The samples studied were from Anloc and Susannah. Analyses of the original basalt and of the red soils formed by the decompn. of basalt show a progressive and almost complete disappearance of Mg, a pronounced loss of Ca and alkalies and a large oxidation of FeO to Fe_2O_3. The water of constitution (H_2O+) was greatly increased; the Al and Ti contents were nearly doubled. The p_H of the soils ranged from 4.57 to 5.58. The quantities of CaO and MgO absorbed were insufficient to neutralize the acid products of decompn. These changes are discussed lithologically. L. W. RIGGS

The origin of the red earth in the most northern region of its occurrence. E. BLANCK, F. GIESECKE, A. RIESER AND F. SCHEFFER. *Chem. Erde* **3**, 44–90; *Chem. Zentr.* **1927**, II, 2778.—With ground profiles on hand, the authors try to explain the origin of the north Italian red earths. The red color is only to be found in lime-contg. soils, when the underlying limestone already possesses this color. Even then the color may be masked, if a sufficient amt. of org. substances is present in the ground. These red soils frequently are the final product of weathering, after the carbonates have been carried away. The real red earth frequently results from deposition of Fe from Fe-contg. solns. G. SCHWOCH

The rain of ashes of April 26, 1928, at Cernauti and environs. N. D. COSTEANU AND AL. COCOSINSCHI. *Compt. rend.* **187**, 449–50(1928).—An analysis of the grayish powder which fell at C. during and after a rain. The powder contained oxides and carbonates of Si, Fe, Al, Ca, Mg, Na and K. E. G. VANDEN BOSCHE

Salt formation in the Chilean desert. W. WETZEL. *Chem. Erde* **3**, 375–436 (1928).—Microscopical examn of thin sections of Chile saltpeter (caliche) showed the presence of halite, nitratine, darapskite, gypsum, anhydrite, thenardite, glauberite, bloedite, "Chile-loeweite" [minute trigonal crystals with ϵ 1.434, ω 1.470, d 2.153 and, after deducting impurities, the compn. $K_2Na_4Mg_2(SO_4)_5.5H_2O$], "chromloeweite" (?), and leonite (?). $KClO_4$, although a product of extn., could not be detected as crystals in the raw caliche. The distribution and relative ages of formation of each of these salts are discussed in detail. It is considered that the nitrates were formed by the action of atm. HNO_3 on the alkali silicates of the rocks of the region. B. C. A.

Paralana hot spring. DOUGLAS MAWSON. *Trans. Proc. Roy. Soc. S. Australia* **51**, 391–7(1927).—The description is mainly geological. The water issues at the rate of 1000 gal. per hr. at a temp. of 62°. The total solids were 75.73 grains per gal., hardness (temporary) 9.01, of which 8.22 were due to Ca, no permanent hardness. The water was strongly radioactive, but further tests are necessary to decide on the radioactive elements present. L. W. RIGGS

Rare gases from thermal springs and the great earthquakes of April 14 and 18, 1928, in Bulgaria. N. P. PÉNTCHEFF. *Compt. rend.* **187**, 243–4(1928); cf. *C. A.* **22**,

1307.—Although the earthquakes have affected greatly the H_2O output of the springs, the % of rare gases and their He/A ratio has not been affected. The earthquakes appear to change the radioactivity of the springs. Thus: in Curie $\times 10^{-10}$ per liter H_2O: Tchonlondja in 1911, 17; in 1928, after earthquake, 44; Kovalnik in 1916, 110; in 1928, after earthquake, 93. G. CALINGAERT

Investigations of van't Hoff and his co-workers on the formation of the Stassfurt salt deposits. J. A. KABLUKOV. *Ann. inst. anal. phys. chim.* (Leningrad) 3, No. 2, 760–841(1927).—A detailed review. G. B. KISTIAKOWSKY

Classification of saturated salt lakes. B. P. KROTOV. *Ann. Inst. Anal. phys.-chim.* (Leningrad) 3, 641–61; *Chem. Zentr.* 1927, II, 2659.—Salt lakes which deposit free salts are divided into 5 types: (1) those in which the ratios: $[Cl]/[SO_4](=x)$ and $[MgCl_2]/[MgSO_4](=y)$ are the same as in ocean water and in which $CaCO_3$ is the only deposit; (2) those poor in $CaSO_4$, where x is abnormally low, and in which NaCl is deposited; (3) those poor in $MgSO_4$, $CaSO_4$ and NaCl, where y is abnormally high; (4) those poor in $CaSO_4$ and NaCl and in which $MgSO_4$ is absent, and where x and y are infinitely great, and (5) the $CaCl_2$ type. The conditions controlling the origin of these types are discussed. An explanation is also given of the frequently observed changes in the compn. of salt waters. C. C. DAVIS

The Tambukan lakes. W. M. BUDRIK. *Verlag Balneolog. Inst. Kaukas. Mineralwässer* 1926, I, 190 pp. and II, 68 pp.; *Chem. Zentr.* 1927, II, 1938.—The Tambukan lakes are typical bitter lakes. Their bottom is covered with black mud contg. hydrotroilite ($FeS.H_2O$). This mud is used for balneological purposes. In the gypsum-contg. slate clay of the Batalin stratum, all fissures contain yellow natrojarosite mixed with a small amt. of loewigite. In the cold season, the lakes deposit Glauber's salt. The mud contains 0.210% of free S. G. SCHWOCH

The meaning of radioactivity in the history of the earth. OTTO HAHN. *Naturw. Monatsch.* 24, 65–76; *Physik. Ber.* 8, 720(1927).—A summary of the detns. of the age of the earth crust from He and Pb content of U minerals, heat content, pleochroic haloes, etc. G. L. CLARK

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. H. ABORN

The best yields (from ores). JOSEF FINKEY. *Metall u. Erz* 24, 29; *Chem. Zentr.* 1927, II, 1073–4.—An explanation of the principle that in ore dressing the best sepn. is obtained when the bed of the concentrate lowest in mineral content or the richest bed of the waste has the same mineral content as the raw ore. J. S. R.

Progress in ore dressing and coal preparation in 1927. ROBERT H. RICHARDS AND CHARLES E. LOCKE. *Mineral Ind.* 36, 634–87(1927).—A review, including crushing and grinding, screening, classifying, settling, filtering, hand sorting, jigs and tables, amalgamation, magnetic sepn., flotation, app., principles and theory, examples of practice, and an extensive bibliography. A. B.

New laboratory flotation cell developed at University of Utah. H. D. KEISER. *Eng. Mining J.* 126, 504–5(1928).—Small cells are built of celluloid, with rivets and impeller shaft coated with collodion. They are easily made and cleaned and have the advantage of transparency, besides avoiding the corrosion which had given trouble in the former cells made of metal. A. BUTTS

Development of flotation at Broken Hill. E. J. HORWOOD. *Eng. Mining J.* **126**, 457–9(1928).—With the lowering of the grade of Broken Hill ore came the necessity of developing means of recovery other than blast furnace smelting formerly in use. H. C. PARISH

Metallurgical treatment of flotation concentrates. DWIGHT. Dwight and Lloyd Sintering Co., N. Y. *Bull. Am. Zinc Inst.* **11**, No. 5–6, 90–106(1928).—The difficulties of handling flotation concentrates as received by the smelter and the advantages of putting them in a coarser condition are given. The universal method adopted has been the Dwight and Lloyd process of sintering. "As ordinarily practiced it consists in arranging the ore on a grate in a thin layer, uniformly pervious to air currents, igniting the combustible elements on the upper surface of the mass and passing air currents through the layer in a downward direction. The ignition thus started on the upper surface is slowly propagated downward in a thin zone of intense oxidation producing at a given point a momentary melting effect, at which moment the semifused material is whipped by the air currents into thin films and cells and the next instant is chilled into a porous, coke-like mass we call 'sinter.'" The application of the process to Pb, Cu and Zn concentrates is discussed. J. W. BOECK

Aluminum and bauxite. ANON. *Mineral Ind.* **36**, 11–27(1927).—A discussion of production, alloys, trade, etc., with statistics. A. B.

Antimony. K. C. LI. *Mineral Ind.* **36**, 28–33(1927).—A review of the Sb market and production. A. B.

Bismuth. C. P. LINVILLE. *Mineral Ind.* **36**, 61–3(1927).—Production and trade in Bi are discussed. A. B.

Cadmium. C. P. LINVILLE. *Mineral Ind.* **36**, 71–3(1927).—A review of production and uses. A. B.

Chromium. WILLIAM D. JOHNSTON, JR. *Mineral Ind.* **36**, 74–80(1927).—Marketing, metallurgy, and output are discussed, with statistics and a bibliography. A. B.

Cobalt. C. W. DRURY. *Mineral Ind.* **36**, 112–6(1927).—Production, trade, metallurgy, and uses are reviewed. A. B.

The manufacture of cobalt oxide and its purification from ores in the wet way. A. WEISSENBORN. *Metallbörse* 17, 1716–7, 1826–7; *Chem. Zentr.* **1927**, II, 1996.—Various methods are described for the decompn. of Co ores and the sepn. of the metal in the solns., especially the sepn. of Mn and Ni from Co. To det. the completeness of the decompn., a *colorimetric method* was developed, which depends upon the property of Co compds. to color thiocyanates blue. C. C. DAVIS

The metallurgy of copper in 1927. LEONARD S. AUSTIN. *Mineral Ind.* **36**, 165–205 (1927).—A review of literature, plant construction and new developments. A. B.

Copper. A. B. PARSONS. *Mineral Ind.* **36**, 117–58(1927).—A discussion of world production, trade, prices, etc., with statistics. A. B.

Utilization of copper and copper alloys. WM. G. SCHNEIDER. *Mineral Ind.* 36, 159–65(1927).—A discussion of prices, uses and general conditions in the industry. A. B.

Copper smelting at Douglas. XVI. E. H. ROBIE. *Eng. Mining J.* **126**, 293–6 (1928).—Current practice and equipment at 2 smelters, the Copper Queen and the Calumet & Arisona, are described. A. BUTTS

Utah Copper's new precipitating plant. H. D. KEISER. *Eng. Mining J.* **126**, 534–7(1928).—Natural surface waters are caused to percolate through dumps of waste rock and overburden carrying 0.3 to 1.0% Cu. The av. flow treated is 1,000,000 gal. in 24 hr., contg. 20 lb. of Cu per 1000 gal. It is conveyed to the plant through a Cu-banded wood-stave pipeline, and is treated in 72 20-ft. pptg. boxes contg. detinned iron scrap. A. BUTTS

Limits of fuel consumption and economy in pyritic copper smelting. E. HENTZE AND FRAULOB. *Metall u. Erz* **24**, 278–85; *Chem. Zentr.* **1927**, II, 1075.—A number of conditions are described which govern the economy of smelting pyritic Cu, namely, the phys. and chem. properties of the ores, their behavior on storage, the operation of the shaft furnace, etc. J. S. REICHERT

The ammoniacal lixiviation of copper ores. A. S. SCHOTT. *Metall u. Erz* **24**, 331–8; *Chem. Zentr.* **1927**, II, 1509.—The chemistry of the process is described together with its technical applications and plant calcns. J. S. REICHERT

Some cases of amalgamation of gold ores. I. PLAKSIN. Univ. Vladivostok. *Arbeiten d. I. Konferenz zur Erforschung von Naturkräften des fernen Ostens* **1927**, 165–78; *Chem. Zentr.* **1927**, II, 2423.—Since river water is not available in the Far East, spring water with a high salt content is often used in the amalgamation of Au ores,

which results in the formation of amalgams contg. Fe and in large losses of Hg. It is shown that sea water is preferable C. C. DAVIS

Recovery of fine gold by amalgamation. EDMUND S. LEAVER. Bur. of Mines, *Information Circ.* No. 6081 (Aug., 1928).—In addn. to accurate assays of representative samples an expert microscopic examn. and report on minerals present and how associated are needed before methods of recovery can be recommended. Loss of "float gold" is due to lack of contact with Hg. Improved recovery can be obtained by a thinner pulp and by introducing swinging amalgamated plates as obstructions to the pulp flow. Improved recovery of "rusty gold" can be obtained by abrasion, grinding or by use of grease-removing chemicals. Fine Au in pyrite or tellurides does not readily amalgamate. The roasting of pyrite concentrates and tellurides improves this condition but does not insure high recovery. To effect amalgamation each particle of Au must come into contact with the Hg. To do this crushed ore and water may be passed over the amalgamated plates in a thin layer and by providing for a drop from each plate to the next in a series. Careless introduction of oils and greases, presence of soluble sulfides, As and Sb all prevent good amalgamation. Cyanidation is usually resorted to for recovering Au lost in amalgamation processes. H. C. PARISH

Gold and silver. M. W. VON BERNEWITZ. *Mineral Ind.* **36**, 213–68(1927); cf. *C. A.* **22**, 51.—Production in the U. S. and the world, prices and metallurgy are discussed and statistics given. A. B.

Speiss and the metals of the platinum group. H. RUSDEN AND J. HENDERSON. *J. Chem. Met. Mining Soc., S. Africa* **29**, 5–10(1928); cf. *C. A.* **22**, 2130, 3610.—A discussion by J. P. Bearswood brought out a method whereby the total platinoids and Au and Ag may be fairly accurately detd., also a few points on the behavior of speisses toward the various platinoids. Several "dry" and "wet" processes giving low results are outlined and a dry method is described which apparently successfully combats the presence of large quantities of NiO in the cupel, loss of Os during cupellation, and splaying of the metals on the cupel. One-half A. T. of speiss is fused with 1 A. T. soda, 1/4 A. T. borax, and 3–4 A. T. red lead. A low flame used at the start is gradually raised. After washing with litharge and reducer the melt is poured. After sepn. of slag and Pb button the slag is re-fused with borax and a mixt. of litharge and sufficient reducer to give a 20 g. button. The 2 Pb buttons are twice scorified with red lead and borax and once with borax only. This treatment removes Ni and Cu. Contrary to the general opinion, the platinoids occurring in speiss show no tendency to settle to the bottom of the Pb. The cleaned button is cupelled with an addn. of 3 g. of Ag, starting at a high temp. which is gradually lowered so as to procure a spongy bead when all Pb has been removed. Parting with HNO_3 is followed by removal of Ag by HCl from the filtrate and elimination of HNO_3 by successive evapns. with HCl, the platinoids are pptd. by Zn onto Pb, filtered, washed, scorified with Pb and borax, the button is cupelled with Ag, and the bead parted with H_2SO_4. The parted bead consisted almost entirely of Pt but did not constitute the total Pt of the speiss. The platinoid value may be obtained with fair accuracy by detg. the Au and deducting from the total. The Au may be detd. in several stated ways. Exptl. results on the behavior of speiss toward the platinoids in S. African Pt ores indicate that the use of *speisses as collectors of Pt ores* is unwarranted. Speisses of As and Sb are excellent collectors of the Os, Ir and Ru, but not of Pt and Pd. While the exptl. results are higher than those of other workers they represent only about 95% of the true content of the speiss, due to the drastic treatment, slight losses during ignition of the metals and on fusion with $KHSO_4$. W. H. BOYNTON

Platinum. GEORGE F. KUNZ. *Mineral Ind.* **36**, 461–76(1927).—World production and technology are reviewed and a bibliography is given A. B.

Metallurgy of lead in 1927. OLIVER C. RALSTON. *Mineral Ind.* **36**, 367–72 (1927).—A review. A. B.

Lead. REIGART M. SANTMYERS. *Mineral Ind.* **36**, 340–66(1927).—The industry in the U. S. and foreign countries is reviewed, with statistics. A. B.

Recovery of arsenic and tin in the Harris process of lead refining. R. WINTER. *Eng. Mining J.* **125**, 893–7(1928); cf. *C. A.* **22**, 3120, 3267.—Sn and Sb are in the form of cryst. oxy salts after sepn. of the free NaOH. The cryst. cake is treated with hot water, free from lime. The quantity of water depends upon the compn. The resultant soln. should contain 10% of combined plus free alkali. Insol. Na antimonate is sepd. by decantation. Sn and As are recovered in 3 steps: (1) pptn. of Sn by $CaCO_3$ and sepn. of Ca stannate; (2) partial causticization of the resulting soln. with lime and sepn. of $CaCO_3$; and (3) pptn. of As with lime and sepn. of Ca arsenate from the resulting 10% soln. of NaOH, which is used for dissolving fresh quantities of spent molten reagent

obtained from the dry operations. Usually the Na stannate is electrolyzed. A small % of As does not affect the efficiency of the electrolysis, but small quantities of impurities are removed by the addn. of Na_2S. Illustrations include the continuous pptn. app. for Sn and As, a special crystallizer for cooling slurry, and the app. for evapg. mixed NaOH and NaCl soln. and melting the product. W. H. BOYNTON

Refining of zincky lead by the Harris process. R. WINTER. *Eng. Mining J.* **125**, 969–70(1928); cf. preceding abstr.—The removal of Zn and the last traces of Sb are discussed and the advantages of the process as a whole are summarized. NaCl is the principal reagent and no solid oxidizer is employed. The molten mixt. of NaCl and NaOH is charged into the reaction cylinder of the machine and circulation of the zincky Pb continued until elimination of Zn and Sb is complete. Na_2O is produced at the expense of NaCl, and Na_2CO_3 is evidently converted to NaOH. Working temps. vary from 390° at the beginning to 460° at the point where elimination of Zn is complete and Sb is being removed. The liquid mass in the working cylinder of the machine is dissolved in strong wash water contg. NaOH and NaCl from a previous operation. The same soln. is used repeatedly till the sp. gr. is 1.35. Pb granules are sepd. and the soln. contg. ZnO in suspension goes to a storage tank where it settles out and the liquor is decanted to the evaporator. The ppt. taken up with water and filtered or the hot liquor is pumped through a heated filter press of the washing type. The Zn cake has: Zn 72–76, Pb 0.2–0.5, and Sb 1–1.5%. Advantages of the process are: low labor and fuel costs, automatic and continuous operation, also the elimination of dross and flue dust treatments and lower metal losses and interest charges. All the Ag and Pb are removed in the primary refining operations. High recoveries of impurities in a marketable form are obtained. W. H. BOYNTON

Manganese. CHAS. H. BEHRE, JR. *Mineral Ind.* **36**, 383–95(1927).—A discussion of production and trade, with notes on technical developments and a bibliography. A. B.

Quicksilver. H. W. GOULD. *Mineral Ind.* **36**, 514–21(1927).—Market, production and technology are discussed. A. B.

Molybdenum. ALAN KISSOCK. *Mineral Ind.* **36**, 401–4(1927).—Progress in the production and use of Mo is outlined. A. B.

Utilization and prevention of molybdenum waste in oxidized lead ore treatment. R. E. HEAD AND VIRGIL MILLER. Bur. Mines, *Repts. of Investigations* No. **2888**, 3 (1928).—Tests were made on a wulfenite ore from the Stardistrict near Milford, which had for its object the sepn. and recovery of the Pb and Mo in sep. products. Microscopic examn. showed that the samples used in the work were composed of wulfenite, plumbojarosite and a small quantity of cerussite. The ore assay showed Pb 16.66, Mo 3.96 and Fe 33.2%. One hundred g. of the ore, ground to 60 mesh, was mixed with 10 g. NaCl and heated for 1½ hrs. at 800–850°. The resultant calcine contained Pb 1.23, Mo 4.98 and Fe 41.0%, and was in a fine state of division. Seventy g. of the calcine were mixed with equal parts of fine coke (8 mesh) and placed in a graphite crucible. This charge was heated at approx. 1000° for 1 hr. About 25 g. of metal in the form of globules were removed by means of a magnet from the cool charge. The pellets contained Fe 87.5 and Mo 11.0%. The results of the test indicate that the method of treatment described can be applied to ores of this type and constitute a procedure by which the waste of Mo is eliminated. DOWNS SCHAAF

Nickel. THOS. W. GIBSON. *Mineral Ind.* **36**, 407–14(1927).—A review, including sources, production, technology and uses. A. B.

Blast-furnace gas as condition indicator. ANON. *Iron Age* **121**, 1686–7(1928).—A discussion of the interpretation of some practical features of blast-furnace gas and the relation these features bear to the chem. and metallurgical reactions going on inside the furnace. H. C. PARISH

Production of high-alumina slags in the blast furnace. T. L. JOSEPH, S. P. KINNEY AND C. E. WOOD. Bur. Mines, *Tech. Paper* No 425, 32 pp.(1928).—See *C. A.* **22**, 1561. H. C. PARISH

Cyanogen and its compounds in the blast furnace. WILLI HAUFE AND HORST VON SCHWARZ. *Archiv Eisenhüttenwesen* **1**, 453–66(1928); cf. *C. A.* **22**, 1309.—These studies are made from considerations of the literature, it being found that differences of opinion are present as to the formation of $(CN)_2$ and HCN in the blast furnace (I). Calcns. using Nernst's approximation formula show that no $(CN)_2$ (in agreement with answers to a questionnaire sent to German I operators) and only small quantities of HCN (unstable) are formed at I temps. A mechanism is given for the formation of cyanides in **I**, it being noted that KCN and NaCN are formed in the hottest parts, while in the cooler upper zones $Ba(CN)_2$ and $Sr(CN)_2$ are formed. The alkali and alk. earths are introduced in large amts. in the ore and fuel. It is assumed that KCN rather than K_2C_2 and K_2CN_2 are formed. All other cyanides (HCN included) formed in I result from secondary reactions with KCN. The 4TiN.TiC present is due to a reaction between Ti, C and N_2, the temp. and pressure playing an important part. This is not a decompn. product of nitrides, nor is KCN instrumental in its production. J. BALOZIAN

The spathic iron ore roasting of the San Fernando mine at Herdorf (Siegerland, Germany). A. WEYEL. *Stahl u. Eisen* **48**, 14–5(1928); cf. *C. A.* **22**, 1748.—A new roasting plant at Herdorf is described. The rectangular shaft furnaces of stone, with well-insulated walls, roasting 58 to 60 tons per 24 hrs. require 2.25% coke or 157,000 kg. cal. Furnaces of the old type used 4.5 to 5% coke. J. A. SZILARD

Shaft flame furnaces in foundries, especially with oil firing. SKAMEL. *Feuerungstech.* **16**, 66–7(1928).—S. describes a cupola with a double hearth, in which two different products may be made, or successive steps in purification carried out. E. W. T

High-temperature crucible furnaces. WILLIAM MASON. *Metal Ind.* (N. Y.) **26**, 392–3(1928).—The design and construction of high-temp. crucible furnaces are discussed. Coke is used as fuel. J. W. BOECK

Refractories and the open hearth. J. R. MILLER. *Blast Furnace & Steel Plant* **16**, 807–8(1928).—Severe service conditions make the refractory problem one involving not only material quality, but the utmost care in construction and use. The roof is of prime importance and should be properly seasoned. Next in importance are the front and back walls. J. W. BOECK

Why tilting furnaces are better. CARL W. PIERCE. *Iron Age* **122**, 693–4(1928).—A more uniform product, greater tonnage and a more economical operation are obtained by the use of a tilting open-hearth furnace as against the stationary type. With the tilting furnace it is possible to remove an unsatisfactory slag and make a new one by the addition of burnt lime. Due to the position of the tap hole in the tilting furnace slow hard taps are eliminated. There is less danger of breakouts in fronts and ends and less bottom trouble in the tilting furnace. The conversion cost in a plant using both stationary and tilting furnaces showed the tilting furnace to be operating at about 80 cents a ton lower than the stationary. DOWNS SCHAAF

Basic open-hearth practice. G. B. WATERHOUSE. Mass. Inst. of Tech. *Blast Furnace & Steel Plant* **16**, 766–9, 922–5(1928).—The process and its history are briefly described. Statistics are given to show the status of the process in the U. S., Great Britain and Germany. The reason for the supremacy of the basic open-hearth process is its ability to deal with raw materials that vary greatly in compn., particularly as to

the amt. of P and large amts. of scrap. Attention is drawn to the great variety and kinds of steel made by this process. The process is not dependent upon one kind of fuel. Prepd. dolomite is being used for refractory purposes, especially in hearth repair. Dead burned imported magnesia is still the standard material for putting in new bottoms. J. W. Boeck

Steel plant waste heat boilers. R. G. Stevens. Bethlehem Steel Company, Johnstown, Penna. *Blast Furnace & Steel Plant* **16**, 931–5, 1050–3(1928).—S. calls attention to the modifications in existing conditions that must be considered in connection with such an installation. The performance of the boiler is secondary to the effect upon the furnace to which it is attached. The possibilities, limitations and location of such boilers are discussed. Explosions produced at each reversing of the valves are particularly severe when a waste heat boiler is inserted between the regenerators and stack. Preventive measures and provisions for these explosions are given. The induced draft fan and method of driving are discussed. The advantage of dry sealed valves, insulated gas flues and types of boilers are pointed out. The justification of a waste heat boiler must be considered, as complete utilization of heat by the primary heating unit promotes economies in excess of those represented by the performance of the boiler. J. W. Boeck

The rehabilitation of rolling-mill equipment in British steelworks. G. A. V. Russell. *Engineering* **126**, 243–5, 274–5, 379–81(1928). E. J. C.

Cold working of ingot iron and steel by drawing. Günter. *Metallborse* **17**, 1573–4, 1629–30, 1685–7, 1741–2, 1911–2; *Chem. Zentr.* **1927**, II, 2225.—A comprehensive report on the refining of metal by cold working. C. C. Davis

Investigations on slags thinly liquid below 1000°; the influence of zinc oxide as a constituent on their viscosity. Helmut B. Wendeborn. *Metallbörse* **18**, 258–9 (1928).—The viscosities of the molten slags are detd. by measuring the elec. work done by a motor in driving a stirrer in the melt, these quantities being approx. proportional to each other. The compns. and properties of 6 slags, fluid below 1000°, are tabulated and compared with values for the same slags contg. ZnO. The temp.-viscosity diagrams of 4 of the slags are plotted, being hyperbolas for homogeneous substances. *Ibid* 426–7.—Up to 20% ZnO may be used in slags, fluid below 1000°, those contg. higher percentages being fluid only at considerably higher temps. Borax in the presence of Fe_2O_3 increases the soly. of ZnO in slags to a high degree. CaO and BaO (up to 2%) promote the fluidity of slags in an extraordinary manner. K_2O, MnO, Al_2O_3, PbO and SiO_2 (above 50%) are undesirable components of slags. Temp.-compn. curves of 2 slag mixts. are plotted for const. degrees of viscosity. For the thinner slag mixts., these show eutectics having about the same compns. With the aid of such curves, the slag compn. for a given temp. and viscosity may be predetd. J. Balozian

The most important properties and the theory of flow-figures. Itiaro Takaba and Katumi Okuda. Mitsubishi Labs., Nagasaki, Japan. *Archiv Eisenhüttenwesen* 1, 511–5(1928).—Expts. are made to answer some of the obscure points regarding flow-figures (I). The focus of I and the directions in which it broadens out are detd. by first making transverse bending tests on mild ingot steel bars, then heating to 200° for 30 min. in a furnace and cooling in the same, and finally etching with Fry's reagent. For studying the strain directions, on loading, in the interior of the specimens, a celluloid model in conjunction with Coker's optical method is used. The magnitudes of the thrust-strains (II) are detd. with a bakelite bar, instead of one of celluloid. The tests show that flow-streaks appear first where II is greatest, and broaden out to where II is still commensurably great. In the middle of the bar the streaks coincide approx. with the largest II, although irregularly around the loading position. The flow-layers and the largest II coincide throughout. I are irregularly formed if the specimens are insufficiently annealed. In 5% Ni steel and 3% Cr-Ni steel I and the sudden break in the load-elongation line (III) can easily be detected, but with rust-free Fe and steel neither is obtained. The sudden break in III and the I result from the same cause. A theory to account for the origin of I is given, according to which, metals with body-centered lattices are more liable to show I than those with the face-centered. J. Balozian

The behavior and requirements of dolomite used in steel works. Otto Jacobs. *Stahl u. Eisen* **48**, 993–5(1928).—The various types of dolomite required in Thomas or Siemens-Martin mills are discussed and experiences with various brands are given. For the Thomas work the chem. compn., grade of sintering, granulation and tar content are of less importance than the use of a thinly liquid, "warm" pig Fe and the addn. of a CaO easy to melt with a low MgO content; the 2 last factors are of the greatest importance in order to obtain a fast and economical operation. For the Siemens-

Martin work it is of advantage to use a dolomite which contains originally some fuel or flux and well calcined in a revolving furnace, because by its use the life of the hearth is increased. J. A. SZILARD

A study of sulfur in the basic process. HAROLD A. GEIGER. *Blast Furnace Steel Plant* **16,** 1201-3(1928).—The desulfurization of blast furnace metal as influenced by the vol., compn. and temp. of the accompanying slag is described. D. S.

Zinc sulfide as an intermediate product of a smelter. W. STAHL. *Metall u. Erz* **24,** 312; *Chem. Zentr.* **1927,** II, 1339.—The observed crystals appeared in clusters on a darker background; they were wine-yellow, transparent, glassy, prismatic, striped, hexagonal bodies. Analysis: Zn 66.08, Fe 0.55, Mn trace, Pb 0.31, S 32.88. Density 4.32, hardness (Moos) 3-4, sol. in HNO_3 and aqua regia. J. S. REICHERT

The influence of carbon on the properties of cast iron. E. DIEPSCHLAG. *Giesserei-Ztg.* **24,** 418-20; *Chem. Zentr.* **1927,** II, 1754.—A review of the various forms in which C can occur in cast iron, *viz.*, graphite, temper C, coarse cementite and perlite, the causes governing the formation of these structural elements, their influence in metallurgical processes and their effects on the mech. properties. C. C. DAVIS

Silicon structural steel from the Bosshardt furnace. K. v. KERPELY. *Zentr. Hutten u. Walzwerke* **31,** 367-72; *Chem. Zentr.* **1927,** II, 1075; cf. *C. A.* **22,** 1563.—The production of Si steel in the Bosshardt furnace is described. The steels produced, in general, show a greater strength than the ordinary product from the Siemens-Martin furnace. J. S. REICHERT

Evidences concerning the location of the carbon atom in boydenite. H. A SCHWARTZ. *Trans. Am. Soc. Steel Treating* **11,** 277-83(1927); cf. *C. A.* **21,** 3872.—Boydenite is a soln. of C in γ-Fe in which one atom of C replaces one of the γ-Fe in the face-centered cubic arrangement and is different in kind from cementite (austenite). A solute atom of any kind can occupy either of 2 types of location in the lattice of a given solvent. W. A. MUDGE

The x-ray investigation of the formation of martensite. KOTARO HONDA AND SINKITI SEKITO. *Sci. Repts. Tohoku Imp. Univ.* **17,** 743-60(1928).—Two series of tests were made on 8 steels ranging from 0.202 to 1.075% C. In series *A* the steels were prepd. in the form of wire 1 mm. in diam., heated to the proper quenching temp. (880° for 0.202% C to 920° for 1.075% C), held at that temp. for 2½ hrs. and then quenched in water. Wires 2.5 mm. in diam. were used in the B series and were filed down to 21 mm. in diam. after quenching. The surface of the quenched specimen was directly exposed to the x-ray in the *A* series, while in the *B* series the surface layer was filed down and the interior of the quenched specimen was exposed to the same ray. The results of the tests show that the outer layer of quenched C steel contains a body-centered tetragonal lattice and the inner portion an ordinary body-centered cubic lattice. The former is identified with alpha martensite and the latter with beta martensite. The mechanism of the formation of martensites from austenite is explained on the basis of the space lattice; *i. e.*, the tetragonal lattice ($c/a = \sqrt{2}$) is first to be compressed uniformly in the direction of the *c*-axis and at the same time uniformly expanded in the perpendicular direction. Alpha martensite is obtained when the axial ratio of the tetragonal changes from $\sqrt{2}$ to 1.07 and beta martensite when the same ratio changes further to 1. DOWNS SCHAAF

X-ray studies of the structure of quenched carbon steel. G. KURDUMOV AND E. KAMINSKII. *Nature* **122,** 475-6(1928).—A great no. of specimens of C steel with the C content ranging from 0.64% to 1.44% were studied by x-ray analysis. The largest dimensions of the specimens were 10 × 10 × 15 mm., and the temp. of quenching varied from 1000° to 1100°. The x-ray study has shown that the tetragonal structure in all specimens exists not only on the surface but also within, at a depth of 5 mm. The presence of austenite was revealed in all specimens. The steels with 0.91 and 1.44% C gave more austenite when quenched in oil than when quenched in water. The present x-ray study shows that martensite can be considered as the solid soln. of the C in α-Fe. DOWNS SCHAAF

Effects observed in quenched liquid steel pellets and their bearing on bath conditions. J. H. WHITELEY. *J. Iron Steel Inst.* (advance copy), No. **8,** 13 pp.(Sept., 1928).—A spoonful of molten metal with a covering of slag is taken from the bath and poured from a height of 2 ft. into cold water 1 ft. or so in depth. Two or three of the pellets formed when the stream of liquid steel is broken up are mounted in Wood's alloy, ground, polished and etched *in situ* with either (1) a soln. of 5 g. of picric acid in 100 g. of 95% EtOH, or (2) Dufays reagent consisting of 100 g. of 95% EtOH, 10 g. of water, 1 g. of $CuCl_2$, 0.5 of picric acid and 1 to 3 g. of HCl. When examd. under

the microscope the particular features to be noted are: (1) sulfide particles, (2) slag and oxide inclusions, (3) gas cavities, (4) structural heterogeneity. Certain deductions can be made from the microscopic examns. of the pellets as to the bath conditions. Also in *Engineering* **126**, 472–4 (1928). DOWNS SCHAAF

A unique installation combining coal and oil firing of an annealing furnace. G. C. DAVIS. *Furnaces, Heat Treating and Forging* **14**, 89(1928).—To prevent the smoking of a coal-fired annealing furnace, a 3" oil burner (in conjunction with a small turbo blower) is so placed that it fires directly over the coal bed. When a green fire is made or fresh coal put on, the burners are turned on, thus doing away with smoke. It has been found that the cost of coal and oil is less than that of coal alone, and that the annealed castings have better properties. J. BALOZIAN

Contribution to the question of the amount of loss during heating in furnaces fired with coal dust. KURT RUMMEL. *Archiv Eisenhüttenwesen* **1**, 499–504(1928).—Since results on the heating loss (I) in coal-dust furnaces vary greatly, an investigation is made. The exptl. method is essentially the *block-process*, the loss in wt. of a small steel block being detd. before insertion and after withdrawal (1250–60° and 1290–1300°) from the furnace. Two series of tests are made: in one the block moves through the furnace in 1–2.2 hrs., and in the other stays in a given position for 1–4 hrs. The furnaces used are fired with hard coal dust, mixed gas (coke gas + hard coal-generator gas), brown coal dust, or brown coal dust + generator gas It is seen that the position of the block in the gas current strongly influences I. I increases as the time of the block in the furnace and, also, its temp. increase. Under av. conditions, I is the same in the coal-dust and gas-fired furnaces. For shorter times of passage through the furnace, the temp. of withdrawal of the block does not greatly affect I, while with greater times the influence of withdrawal temp. is considerable. With short times of standing in dust-fired furnaces (especially with ash-rich brown coal dust), I is greater than in the gas-fired, and is smaller for longer time. J. BALOZIAN

The decarburization of steel during heat treatment. M. BONZEL. *Aciers spéciaux* 2, 456–61(1926); *Chimie et industrie* **20**, 262(1928).—A discussion of the decarburization of steel in various gases at different temps., and of the precautions which should be taken to prevent it during heat treatment. A. PAPINEAU-COUTURE

Ethylene as gas fuel for welding. K. E. SKARBLOM. *Svensk Kem. Tids.* **40**, 119–25(1928).—An argument for the use of C_2H_4 in place of C_2H_2, H_2 or illuminating gas in welding, R R. signals, etc. The inner cone of the flame adjusted for welding is longer with C_2H_4 than with C_2H_2. C_2H_4 is made by heating EtOH vapor to 500°+ in the presence of kaolin, $AlPO_4$, ThO_2 or W_2O_5 Et_2O can be ruled out by proper catalysts and heat manipulation. Welding tests with C_2H_4 were satisfactory. A. R. ROSE

The change of elastic constant in metals caused by cold-working. KOTARO HONDA AND RYONOSKE YAMADA. *Sci. Repts. Tohoku Imp. Univ.* **17**, 723–42(1928).—Previous contradictory results as to the changes in Young's modulus of elasticity due to cold-working of metals are reviewed, and a theoretical analysis is given showing that this modulus must be diminished, like the d., by cold-working. Fe, steel, Cu, brass and Al were tested in tension, and the true elastic deformation was detd. as the difference between total and permanent deformation. By working with small loads, the stress-strain curves were studied near the origin. Single Fe crystals showed a decrease of 3% in the modulus, due to cold-working, which agrees with the theory based on the decrease in d. The modulus did not recover after low-temp. annealing of strained single crystals, although when annealed above 300° they softened; they showed no elastic after-effect when unloaded after a plastic deformation. The decrease in the modulus, due to cold-working, in ordinary Fe and other metals was 6 to 10%, and likewise agreed with the theory based on changes in d. The modulus recovered from the cold-working effect on aging for several hours or more quickly on heating up to 200°. The recovery was more difficult when working had been more severe. GEO. F. COMSTOCK

Recent investigations on the resiliency of metallurgical products at the experimental institute of the State railways. FORCELLA. *Riv. tech. ferrovie Italiane* **1927**, 31; *Rev. métal.* **25**(Extraits), 357(1928).—Resiliency tests on a large no. of rails, tires, coupling hooks and sheet metal were made on a Charpy 30-kg.m. machine with Mesnager test bars. The results showed that parts exhibiting normal elongation failed in service when the resiliency was low. By measuring the fragility of the most fatigued portion of the metal, it was observed that failure always took place when the resiliency was less than 0.5 kg. m., even though there was no localized defect; *e. g.*, the working surface of a rail which had failed in service, having a tensile strength of 80 kg. per sq.

mm. and elongation of 14% and free from local defects, had a resiliency of 0.3 kg. m., while the resiliency of the remainder of the rail was 1.5 kg. m. In order to obtain concordant results in the resiliency test, it is recommended that the test piece be taken so that the notch will be perpendicular to the plane of rolling. In all the tests which gave low resiliency, it was found that the results could be explained from the results of micrographic, macrographic or chem. examn. Investigation of the effects of a 3-mm. hole perpendicular to the notch of the Mesnager test bar showed that: (1) When the resiliency, detd. in the usual way, is 0.3-3.5 kg. m., the presence of the 3-mm. hole appreciably increases the resiliency (expressed in kg. m. per sq. cm.). (2) When the resiliency is approx. 3.5 kg. m., its value is not affected by the 3-mm. hole. (3) With resiliencies higher than 3.5 kg. m. (the tests were carried out on metals having resiliencies up to 24 kg. m.) the resiliency is decreased by the presence of a 3-mm. hole; the decrease becomes larger as the resiliency increases. A. PAPINEAU-COUTURE

Flow characteristics of bars and tubes, both pressed and drawn. HERMANN UNCKEL. *Z. Metallkunde* **20**, 323-30(1928).—The process of flow is first studied by pressing out bars from a plastic mixt. contg. beeswax, vaseline and chalk, arranged in differently colored layers. A block built up of alternate sections of Al and an alloy of Al contg. 1% Cu is then studied both in pressing and drawing and the nature of the flow is described. H. STOERTZ

Steel castings and pouring temperatures. A. TENIVELLA. *Met. italiana* **20**, 342-5(1928).—A discussion of the influence of the temp. of pouring on the quality of steels. Emphasis is laid on the desirability of avoiding high pouring temps. even with thin castings. C. C. DAVIS

The specific heat of iron below 400°. WM. H. DEARDEN. *Iron Steel Inst. Carnegie Scholarship Mem.* **17**, 89-108(1928).—The curve showing the relationship between the variations in the sp. heat of Fe and temp. plotted from the results of exptl. work, the vacuum calorimeter method being used, rises steadily up to a temp. of 100°, then there is an abrupt rise, followed by a somewhat slower fall to 180°, and then a smooth rise up to 400°. The cusp in the curve is quite marked, implying some phys. change taking place in Fe in the neighborhood of 115°. The result is shown to be in accord with abnormalities and discontinuities occuring in many other properties of Fe at about the same temp. DOWNS SCHAAF

The effect of oxygen on iron and steel. I. ANON. *Metallurgist* (Suppl. to *Engineer* **146**, No. 9) 116-8(1928).—A review of recent literature on the soly. of O in Fe and of methods of detg. O in steel. **II.** *Ibid* (Suppl. to *Engineer* **146**, No. 13) 130-2.—A review of the structure of O-bearing steels, of the removal of O by Mn and of the effect of O on phys. and elec. properties. D. B. DILL

The properties of silicon-carbon-iron alloys and a new theory of cast iron. D HANSON. *Giesserei Z.* **15**, 148-58(1928); *Iron and Coal Trades Review* **115**, 437-42(1927). —See *C. A.* **22**, 751. J. BALOZIAN

Apparatus and methods for measurement of the Hertzian hardness. R. ESNAULT-PELTERIE. *Engineer* **146**, 220-2(1928); cf. *C. A.* **22**, 4092.—The area of contact of two balls is estd. by measurement of elec. resistance to the passage of a current through the point of contact. It is shown that the theory of elec. resistance of 2 conductive bodies in contact justifies this method. D. B. DILL

The Rockwell hardness test. J. E. MALAM. Kynoch, Ltd., Birmingham, Eng. *J. Inst. Metals*, advance copy **472**, 20(1928).—Annealed strips of Cu, brass and Cu-Ni with 20% Ni, all $^1/_4$ in. thick, were cold rolled in various amts. up to 60% and were tested for hardness by the Rockwell, Brinell and scleroscope methods. Balls of $^1/_{16}$ in. and $^1/_8$ in. diam., resp., were used in the Rockwell machine, and a 3 mm. ball was used on the scleroscope hammer. The hardness values above 20% reduction by cold-rolling did not increase as much when measured by the Rockwell method as by the Brinell. A linear relation is shown between Rockwell nos. and reciprocals of the Brinell nos.; also between Brinell and scleroscope nos. The Rockwell machine as usually calibrated does not give as good a measure of the resistance to penetration of these cold-worked alloys as the Brinell method, and a new Rockwell scale agreeing with the Brinell nos. is suggested. Formulas for correlating the results of the 3 methods are proposed for some of the alloys, and discussed. Defects in the Brinell test, as reported by other investigators, are reviewed, and improvements suggested are the adoption of the projected area of impression as divisor in computing the no. and a correction for friction. The unstandardized nature of methods in use for hardness testing is unfortunate, and the situation might be corrected by a committee. The present arbitrary Rockwell scale is not considered suitable for worked non-ferruos alloys. G. F. C.

The relation between the pressure and the diameter of impression in hardness

test. KINNOSUKE TAKAHASI. *Sci. Repts. Tohoku Imp. Univ.* **17**, 843–56(1928).—Exptl. results in indentation hardness testing are given to show that under very small pressures the pressure will be proportional to the square of the diam. of impression. The app. consisted of an Amsler 5-ton tensile testing machine to which a 10 mm. Brinell ball was firmly attached, and a specially constructed instrument for measuring the depth of indentation. Tests were made by applying 5 to 100 kg. loads and measuring the depth for every 5 kg. up to 30 kg. and for every 10 kg. above 30 kg. on specimens of Al, Cu, Zn, brass and on annealed and quenched C steels contg. 0.1, 0.3, 0.5, 0.7 and 0.9% of C. DOWNS SCHAAF

X-ray investigation of the internal stress of carbon steels. SINKITI SEKITO. Tohoku Imperial Univ. Sendai. *Z. Krist.* **67**, 563–9(1928)(In English); cf. *C. A.* **22**, 2911.—The broadening of the spectral lines by the action of cold-working of C steel is similar to that of Cu (cf. *C. A.* **21**, 3589). C steel, cold-drawn to give a reduction of 1/4.3 in diam., shows a max. distortion of the space lattice of 0.4%. The calcd. internal stress of 84 kg./sq. mm. is slightly less than the tensile strength. Annealing at 400° releases most of this stress. L. S. RAMSDELL

Properties of materials at high temperatures. III. "Creep" of Armco iron. H. J. TAPSELL. Dept. Sci. Ind. Research, Eng. Research. *Spec. Rept.* No. **6**, 11(1928); cf. Tapsell and Clenshaw, *C. A.* **21**, 3333 —"Creep" tests made on Armco iron at 136° under a load of 25.7 tons per sq./in. showed that creep had practically ceased in 22 days. Stress-strain relations of specimens which had been creep-tested at 150°, 237°, 325° and 390° indicated that plasticity progressively decreased and the new limit of proportionality acquired by the material was at all temps. much greater than the value of the original material. It is considered that a hardening process occurs during creep similar to that taking place in the neighborhood of the slip planes during a fatigue test. B. C. A.

Influence of heterogeneity of structure on the appearance of the fracture and on the resistance of homogeneous iron and steel plates. RAFFAELLO ZOIA. R. Scuola d'Ingegneria, Torino. *Notiz. chim.-ind.* **3**, 571–6(1928); cf. *C. A.* **22**, 373.—Tests were made of 511 samples of homogeneous Fe and steel plates for reinforced concrete, including: (1) macrographic examn. of transverse sections after attack by various standard reagents; (2) examn. of the characteristics of fractured surfaces; (3) detns. of the tensile strength and elongation at rupture; and (4) detns. of the hardness (Brinell). The most interesting of the results are described, with photographic reproductions, the latter showing especially the effects of slag and blow-holes. C. C. D.

Strain effects in mild steel. HENRY S. RAWDON. *Eng. News-Record* **101**, 244–50 (1928).—An extensive discussion of strain in mild steel, its effects and detection. The changes corresponding to "yielding" under stress are very evident and may be demonstrated (*a*) by strain markings on polished surfaces or the flaking of oxide or other coatings, (*b*) by macroscopic etching with acidified Cu solns., (*c*) by microscopic examn. of polished surfaces subsequently strained, and (*d*) by hardness surveys. Stress beyond the yield point produces a progressively greater change in the appearance and structure of steel. The surface, which becomes completely free of any scale initially present, assumes a mat appearance, entirely obliterating the strain markings produced during the first yielding of the metal. The grain structure is greatly changed and a fiber like structure is approached with high degrees of straining. The corrodibility may be greatly increased as a result of permanent strain. R. E. THOMPSON

The influence of cold-hardening on the fragility of mild steel. PIERRE DEJEAN. Inst. Polytechnique de Grenoble. *Chimie et industrie* Special No., 337–42(April, 1928); cf. *C. A.* **21**, 3590 —The previously reported results on the effects of compression on fragility are given and compared with the effects of traction on the same steel. In the latter case the fragility increases with the elongation, finally reaching a value which remains practically const. irrespective of further elongation; but in no case is this const. fragility as high as the one caused by subjecting to a compression greater than the previously found crit. value. A. PAPINEAU-COUTURE

Hardness and its relation to the cold-working and machining properties of metals. II. HUGH O'NEILL. *Iron Steel Inst. Carnegie Scholarship Mem.* **17**, 109–56(1928); cf. *C. A.* **21**, 1787.—The nature of deformation by scratching is considered in detail and a description is given of the construction of a new form of sclerometer using a 1 mm hemispherical diamond, and its application to the study of directional hardness in both annealed and strained single crystals of metal. Indentation tests are considered in connection with the machining properties of metals and the Brinell value H_u (which is equal to $^1/_2$ the mean pressure per unit area required to give the max. amt. of deformation in the ball test) is more valuable than the normal Brinell no. in correlating

hardness with machinability. A distinct similarity is noted between curves connecting true stress with some function of strain, irrespective of whether deformation is produced by the tensile, compression or ball indentation tests. A stress called the "pressure of fluidity" is discussed and has a value twice as high as the *true* tensile breaking stress and bears an inverse relation to Richard's values of coeff. of compressibility. It is suggested that elastic plus plastic deformation must be utilized in the measurement of hardness, and a method is described in which this is done for the hardest of metals.

DOWNS SCHAAF

The change in tensile strength due to aging of cold-drawn iron and steel. L. B. PFEIL. *J. Iron Steel Inst.* (advance copy) No 6, 15 pp. (Sept., 1928).—The exptl work consisted in cold-drawing without annealing a series of steels of varying C content and of varying heat treatments, followed by tensile tests at different stages of reduction and at different lengths of time after drawing Annealed metal $^1/_2''$ in diam. was drawn from 6/0 S.W.G. to 16 S.W.G without annealing, each die decreasing the diam. by approx 1 gage no. The drawing was carried out at the very slow rate of 3″ per min. The material tested contained 0.11% C, 0.006% Si, 0.70 Mn, 0.028% S, 0.016% P and lower C content metal was produced by heating the 0.11% C stock in H for different time periods. By using the tensile test as a measure of the capacity of the metal to undergo age-hardening after cold-drawing, it is shown that this phenomenon is chiefly due to the presence of C. C-free Fe is not subject to aging, but Fe contg. as little as 0.0025% C shows well-developed aging Since Fe contg. FeO also exhibits this phenomenon it is suggested that both C and FeO are sol. to a small extent in ferrite at ordinary temps., but that the soly. is less in distorted crystals, with the result that hardening and strengthening of the "duralumin" type occur after cold drawing. Also in *Engineering*, 126, 439–41(1928).

DOWNS SCHAAF

Magnetic method for the determination of the elastic limit of iron and steel. B. A. HOWLETT. Rose Polytech. Inst. *Proc. Indiana Acad. Sci.* 37, 240–4(1927) —H. gives a summary of thesis work done by Victor E. Schlossberg and P. E. Duffendach. Samples of steel and wrought iron were subjected to a tensile stress while under the influence of a fairly strong elec. field and the change in flux was measured. At the yield point of materials abrupt changes occur in the stress-strain curves and correspondingly abrupt changes were observed in the rate of change of flux at the true elastic limit in the samples under the stated conditions. D. used the method for malleable cast iron. Here there were a number of peaks but the first peak was taken to correspond with the elastic limit.

S L B. ETHERTON

The magnetic and electrical properties of cast iron. J. H. PARTRIDGE. *Iron Steel Inst. Carnegie Scholarship Mem.* 17, 157–90(1928).—Exptl tests prove that addn of Si to cast Fe decreases its magnetic induction and its remanence, and when present in amts. not exceeding 5%, it also decreases its max. permeability. Co increases the magnetic induction, remanent magnetism, and max. permeability of cast Fe, the high induction being due to the graphite existing in a very fine state of division. The addn of Ni decreases the magnetic permeability of cast Fe to such an extent that it becomes practically non-magnetic when about 15% of this element is present. P does not seem to have any marked effect on the permeability or induction of cast Fe. C has a very marked influence on the magnetic properties of cast Fe. If present as graphite in the nodular form, high induction is obtained, if in the form of flakes the Fe possesses low magnetic induction. If the ground-mass is ferrite, low hysteresis loss and high permeability appear to be fundamental properties of the material. If the Fe has a pearlite matrix it will also possess high hysteresis loss and comparatively low permeability The higher magnetic induction and permeability are obtained with cast Fe which has been annealed.

DOWNS SCHAAF

Testing machines for measuring the strength of metals. W. DEUTSCH AND G. FIEK. *Z. Ver. deut. Ing.* 72, 1173–82(1928).—A description of machines for testing the resistance of metals to tension, compression, bending and impact.

What is fatigue? K. LAUTE AND G. SACHS. *Z. Ver. deut. Ing.* 72, 1188–9(1928).—The authors tested a number of Ni bars in a high-frequency alternating stress machine and found that, for a given amplitude of deformation, the number of revolutions to produce rupture is decreased by interposed annealings for half an hr. at 750°. It is assumed that a gradual disruption of atomic cohesions leads to the formation of macroscopic cracks.

H. S. v. K.

Resistance to fatigue and to shock and hardness of certain nickel and chrome steels for gears. A. HULTGREN. *Ing. Vetensk. Akad. Handl.* No. 59, 1–55(1927); *Chimie et industrie* 20, 264(1928).—A study of the properties required of steels for

automobile gears and the most suitable heat treatments, including the usual mechanism of the defects which develop in gears, the nature and distribution of the strains in the teeth of the gear, and the danger of fissuring and % of deformation during heat treatment. The suitability of certain Ni and Cr steels for the purpose was studied by means of fatigue (torsion), shock and hardness tests of a no. of cemented, oil-quenched or air-hardened steels. For parts subjected to repeated or alternate strains, but not to severe shocks, cemented Ni and Cr steels were found to be the best; next came oil-quenched steels (which should preferably be polished after heat treatment); while the air-hardened steels were inferior to the others. A. PAPINEAU-COUTURE

Replacement of tension and torsion tests of iron and steel wires by a ball compression test. BERNWARD GARRE. Techn. Hochschule, Danzig-Langfuhr. *Zentr. Hütten- u. Walzwerke* **31**, 557–59; *Chem. Zentr.* **1927**, II, 2537.—Expts. show that in many cases under certain conditions tension and torsion tests can be replaced with sufficient precision by measurements of the max. diam. of a compression made by a spherical ball on the wire. C. C. DAVIS

The use and interpretation of the transverse test for cast iron. J. G. PEARCE. *J. Iron Steel Inst.* (advance copy) No. **5**, 18 pp. (Sept., 1928).—By casting and testing cylindrical transverse test bars conforming to British Eng. Standards Specification No. **321**, of varied sizes and compns., it is possible to chart relations between size and strength, and between compn. and strength. The transverse rupture modulus increases continuously as the test-bar diam. diminishes until the point is reached at which the metal ceases to be gray. The size-strength curve is a useful index to the behavior of cast iron in thick sections, and the compn. strength curve obtained from a series of these should be of great assistance both to the designer of cast-iron structures and to the foundryman. P. hopes the expression of transverse strengths as rupture moduli will become general. DOWNS SCHAAF

Structure and strength of cast iron. G. NEUMANN. *Stahl u. Eisen* **47**, 1606–9 (1927).—The tensile strength, hardness and microstructure of gray cast iron as cast, after annealing at 850° and quenching in oil, and after quenching and annealing at 600–650° have been examd. The results confirm Bardenheuer's observations (*C. A.* **22**, 373) that the distribution of the graphite plays a far greater part in detg. the mechanical properties than does any other micro-constituent. The nature of the ground mass has an effect only on the hardness, its effect on the tensile strength being masked by the action of the graphite. The highest tensile strength is obtained with the min. amt. of graphite, provided it is evenly distributed throughout the metal in the form of fine flakes. B. C. A.

The tensile properties of tempered cast iron. RUDOLF STOTZ. *Giesserei Z.* **15**, 145–8(1928).—Standards for the min tensile strengths and % elongations of white and gray tempered cast Fe, as proposed by the "Verein Deutscher Tempergiessereien," are found by expt. to be too low. J. BALOZIAN

The qualitative and economic importance of acid steel casting, especially acid electro-casting. VIKTOR ZSÁK. *Giesserei-Ztg.* **24**, 413–7; *Chem. Zentr.* **1927**, II, 1754.—A study of the problem of the economy of production of steel by the acid process, with a crit. evaluation of the properties of the products. It is shown that for steel castings with an allowable P content not over 0.05%, the basic process is in general preferable, and that with an allowable P content not over 0.075% either process is superior economically in all cases where the finished casting may contain 0.1% P. C. C. DAVIS

Some properties of cold-drawn and of heat-treated steel wire. S. H. REES. *J. Iron Steel Inst.* (advance copy) No. **7**, 16 pp. (Sept., 1928).—The effect of low-temp. heat treatment on the mech properties of cold-drawn Cr-V steel wire contg. C 0.42, Cr 1.11 and V 0.20% are shown in tables and curves. The microstructure of the cold-drawn steel showing highly distorted ferrite and sorbitic pearlite drawn out in a longitudinal direction was not changed until a temp. of 450° was exceeded, when a slight coalescence of the carbide took place. Heating into the crit. range (750°) and cooling in air gave troostite and sorbite, and heating to a higher temp. (900°) resulted in a structure of acicular ferrite and sorbitic pearlite. Heating the cold-drawn material increases its density; the increase occurs principally after heating at 600° and above, the density after reheating to 750° was 0.33%. Tables showing the effect of preliminary low-temp. heat treatment on the loss of tension and on permanent set at various temps. are included. The complete restoration of elasticity at atm. temp. requires a treatment at 300° for the Cr-V steel, and other changes which occur on low-temp. heat treatment are comparable in extent when the Cr-V wire has been heated at a temp. about 100° higher than that applied to the C steel wire. Under high stresses

at raised temps., oil-hardened and tempered wire is decidedly inferior to cold-drawn and low-temp. heat-treated wire of the same compn. DOWNS SCHAAF

The properties of cast iron at low temperatures with special regard to cast-pipes and cast-pipe conduits. C. PARDUN AND E. VIERHAUS. *Giesserei Z.* **15,** 99–102(1928).—An attempt was made to find the reason for the occasional fracturing of large Fe castings at freezing temps. In the present research bending, breaking, impact and hardness tests were made on machine castings, cast-pipes, hematite castings and Fe to be used in thin-walled castings, at 0°, —20°, —35°, —80° and —180°. There is no appreciable change in these properties between 0° and —80°, whereas at —80° and —180° there is considerable increase in all of them with decrease in the temp., excepting the impact strength which decreases. These results show that the fracturing of Fe castings cannot be due to a slackening in their tensile properties, but rather to strains set up during contraction in the cold air, or in the cases of conduits, in the frozen earth bed. J. BALOZIAN

Case-carburization in presence of ferro-silicon. R. C. SPENCER AND E. G. MAHIN. Univ. of Notre Dame. *Proc. Indiana Acad. Sci.* **27,** 265–9(1927).—A general discussion. S. L. B. ETHERTON

Diffusion of hydrogen in iron. E. G. MAHIN. Univ. of Notre Dame. *Proc. Indiana Acad. Sci.* **37,** 272–6(1927).—Metals, especially when molten, may dissolve gases and during crystn. blow holes may be produced as a consequence. Iron rolled into sheets becomes coated with oxide and the sheets require pickling in HCl or H_2SO_4 to remove the scale. The concn. of the acid, the temp. and the duration of treatment should be such as will remove all the oxide but have the least attack on the free iron. However, some attack on the iron occurs and H is evolved. At ordinary temps. mol. H will not dissolve in Fe but during pickling, when atomic H is evolved, the gas dissolves and ultimately diffuses through the iron sheets. The metal must be annealed to remove the gas or it will be brittle and small blisters may appear during the coating process. A corresponding effect is thought to occur in steam boilers, the H evolved from the alk. waters being absorbed in the ferrite of the shell. Edwards found that for 0.1 *N* acid the rate of soln. and diffusion of the H through a clean sheet of hot rolled mild steel was inversely proportional to the temp. and the rate of diffusion increased rapidly with increasing concn. of H_2SO_4 from 5 to 15% and thence slowly. Edwards' theory is that atomic H dissolves in the steel and on reaching the outer surface combination of the atoms takes place so that mol. H escapes. A discontinuity of the metal causes gas pressure; hence the blisters. Such pressures may be high, for Cailletet has shown that diffusion occurs against 14 atm. pressures. M. used the tops of test tubes, de Khontinsky cemented to a steel strip, the under side of which had been polished and etched for microscopic examn. and lightly smeared with petrolatum. With H_2SO_4, bubbles like vortex rings were observed on the under side in 2 hrs. Apparently, the conclusion of Edwards is correct, *i. e.*, that there is no preferential path of gas travel, which would not be expected if the gas preferred amorphous grain boundaries. S. L. B. ETHERTON

The decomposition of the austenitic structure in steels. RALPH L. DOWDELL AND OSCAR E. HARDER. *Trans. Am. Soc. Steel Treating* **11,** 217–32, 391–8, 583–606, 781–90, 959–74(1927); **12,** 51–68(1928).—Commercial alloy, plain C steels and special lab. steels were used. Many photomicrographs are presented. *I. Decompn. during normal quenching.*—High C, alloy steels give increased quantities of austenite on quenching in oil from a high initial temp. rather than from normal quenching temps. Drastic quenching produces martensite at the edges. *II. Decompn. in liquid O.*—Submersion in liquid O_2 gave nearly complete decompn. for C steels and little or no decompn. with Mn and high-speed steels. More martensite may be produced at the interior than at the surface. Martensite forms at a rapid rate and immediately after submersion. Microstructures are similar to those from normal quenching and indicate a recrystn. phenomenon which shows itself first along slip planes and is accompanied by an increase in hardness and a decrease in density. *III. The effect of drawing or tempering; normal stresses.*—The decompn. temp. for austenite is always higher than for martensite in the same or similar steels. In C steels the martensite needles show progressive darkening at 100° as time and temp. are increased and indicate a slow pptn. of carbide until troostite is formed. Alloy steels behave similarly but are more stable and require higher temps. and longer time. Nodular troostite usually forms at grain boundaries, along slip planes or along martensite, cementite or troostite patches. *IV. Effect of stress.*—Martensite was produced from austenite by tensile but not by bending or upsetting stresses. Deformed austenite is rendered less stable on heating or on cooling. *V. X-ray studies.*—The General-Electric x-ray app. was used. Transformations

producing martensite give α-particles which are too small to be recorded on a crystallogram. C is held within the space lattice and does not replace the Fe atoms. X-ray results supplemented and confirmed mech. and microstructural data. *VI. Proposed theory for hardening and tempering steels.*—Austenite forms by soln. reaction between ferrite and carbide. Holding at temps. above the critical point causes grain growth. All com. rates of cooling produce unstable conditions and result in the delayed appearance of pptn. and transformation of phases. Recrystn. continues during aging. Tempering of austenite involves recrystn. from γ- to the α-lattice. Carbide particles grow in contact with the α-lattice and through the α-lattice as the solvent.

W. A. MUDGE

The influence of pearlitization below the AR_1 point on the mechanical properties of carbon steels. JOAQUIN ORLAND. *J. Iron Steel Inst.* (advance copy) No. **4,** 8 pp. (Sept., 1928).—Comparison is made of the mech. properties of lamellar pearlite in normalized steel with very fine globular pearlite obtained by tempering a series of C steels, the C content varying from 0.15 to 1.05%. On tempering quenched steel a finely granular pearlite is obtained, which gives to the steel both a tensile strength and an impact resistance greater than that given by lamellar pearlite in annealed steel. The best tempering temp. is given as 500° for the low C content steels, and 580° for the higher percentages of C.

DOWNS SCHAAF

The influence of varying strains and annealing temperatures on the growth of ferrite crystals in mild steel. C. A. EDWARDS AND TAKETO YOKAYAMA. *J. Iron Steel Inst.* (advance copy) No. **2,** 23 pp. (Sept., 1928).—The influence of varying degrees of cold-work, annealing temps. and annealing times upon grain growth in mild steel was investigated. Cold-drawn steel in the shape of 1/2" rounds was used for the tests, the bars contg. 0.08% C, trace of Si, 0.30% Mn, 0.032% S and 0.018% P. After normalizing by heating at 950° for 1/2 hr. in an atm. of coal gas, the bars were strained from 4 to 14% elongation, in steps of 0.5 to 1.0%. Pieces 1" long from the strained bars were wrapped in thin sheet metal and annealed in an atm. of coal gas at temps. ranging from 600 to 920° for periods of time varying from 2 hrs. to 7 days. The crit. strain for max. growth for an annealing temp. of 500° was 10%, for 600°—8%, 675°—6%, 700°—5% and for 725°—4%. The results of the tests prove that the higher the annealing temp., providing the straining corresponded with the crit. degree, the larger were the crystals, but they required a longer time to grow. Strains less than the crit. amts. followed by annealing did not cause crystal growth. As the degree of straining was increased above the crit. amt. the smaller were the crystals that were grown. Very severe strains caused recrystn. The longer the period of annealing and the higher the temp. up to A_1 point, the larger were the ferrite crystals formed. Other things being equal, the higher the temp. above the A_1 point, the smaller were the crystals produced. More extended crystal growth took place in the direction of straining than in the transverse direction. The growth of columnar crystals at or below 725° is due to the combined influence of cold-work and decarburization.

DOWNS SCHAAF

The gaseous cementation of iron and steel. IV. The action of mixtures of carbon monoxide and ammonia on iron and steel and its bearing on the process of cementation. ARTHUR BRAMLEY AND GEOFFREY TURNER. *Iron Steel Inst. Carnegie Scholarship Mem.* **17,** 23–66(1928); cf. *C. A.* **22,** 207.—Cementations of Armco Fe were made at various temps. with mixts. of CO and NH_3 and with mixts. of CO and H. In series A of the 4 sets of expts. the ratio of CO to NH_3 in the gases entering the reaction chamber was kept const., and the rate at which they were passed through the furnace was the same in all cases. The cementations were conducted at various temps. ranging from 700 to 1050° at intervals of 50°, and the process was continued in each case for 10 hrs. The ratio of CO to NH_3 in the gases delivered into the cementation chamber was varied in series B. Series C and D were arranged to correspond with series A and B, resp., but with the introduction of H instead of NH_3 into the CO. The test results prove that the carbonizing action of mixts. of CO and NH_3 is much greater than that of CO alone. The carburizing properties of mixts. of CO and H were stronger than CO alone, but not so intense as corresponding mixts. contg. NH_3. The micrographs show that the microstructure of the Fe-C alloys is entirely altered by the presence of N; especially is this the case when the cementations were made at temps. below 800°; above 800° very marked segregation of cementite takes place. **V. Determination of the iron/iron-nitride eutectoid. The action of ammonia on steels containing different concentrations of carbon.** ARTHUR BRAMLEY AND FREDERICK WARDLE HAYWOOD. *Ibid* 67–87.—A cylindrical bar of Armco iron was nitrogenized by heating it for sometime at a suitable temp. in an atm. of N and NH_3. A portion of the cemented bar was turned down on a lathe, the thin concentric layers of metal were ana-

lyzed, and a curve was plotted showing the relationship between the percentage of N present in the steel and the depth below the surface. A transverse section of another part of the bar was photographed and the prints were mounted together, so that a large composite micrograph was obtained. A millimeter scale was placed on the print along a line parallel to the edge representing the surface of the specimen, and at a known distance from it. With the aid of a magnifying glass, that portion of the line passing over the dark areas in the micrograph was measured. This was repeated along lines corresponding to depths increasing by 0.1 mm. below the surface of the specimen, so long as any dark particles were noticeable. If, along one of these lines, a strip of metal of infinitesimally small breadth and thickness be considered, that portion of this infinitely thin column of metal which is of eutectoid compn. will be known, and from the N concn.-depth curve previously mentioned the av. age percentage of N in this strip of metal can be ascertained. The Fe nitride-Fe eutectoid contains 2% of N; the eutectoid temp. has been deduced as 608° approx. A detn. of the Fe-FeC eutectoid and the soly. of C in α-ferrite, using the same method gave figures of 0.915% to 0.892% C for the eutectoid, and an av. value of 0.04% as the soly. of C in α-Fe. D. S.

Heat compression studies with pearlitic, martensitic and austenitic steels. HANS HENNECKE. *Sitzgb.* No. **94,** *Werketoff. Ver. deut. Eisen* No. **5,** 16 pp. (1926); *Physik. Ber.* **8,** 916(1927).—The results of static and dynamic investigations on 21 com. normalized steels lead to the conclusion that the larger increase in resistance to deformation of pearlitic steels at the α-γ transformation is due to the decrease in velocity of recrystn. above Ac_3. The tension distribution, deduced from measurement of grain size, agrees with calcns. from Mohr's law. Dynamic compression studies showed only for low-C steels a small elevation of deformation resistance at the α-γ transformation. Numerous other expts. are described. G. L. CLARK

Iron-chromium equilibrium diagram. P. OBERHOFFER AND H. ESSER. *Stahl u. Eisen* **47,** 2021–31(1927).—The equilibria in the system Fe–Cr have been detd. by thermal analysis and Röntgenographic investigation of a series of alloys made from electrolytic Fe and the purest Cr. The metals form a continuous series of solid solns with a min. m. at 1405° for the alloy with 14.5% Cr. The temp. of the A4 transformation decreases steadily with the addn. of Cr at the rate of 26° for every 1% Cr up to 14% Cr. The A3 temp. falls to a min. of 840° (heating) and 812° (cooling) with 8% Cr, then rises with further addn. of Cr, the curve finally meeting the A4 curve at 14% Cr; thus the field of γ-ion is limited to alloys contg less than 14% Cr. The temp of the A2 transformation rises to a max. of 771° with 2% Cr, then falls steadily in an almost straight line to 0° with 75% Cr. The heat evolved in the A3 and A4 transformations decreases rapidly with increase in the Cr content of the alloys.
B. C. A.

The inner structure of chromium steel. ED. MAURER AND H. NIENHAUS. *Stahl u. Eisen* **48,** 996–1005(1928).—A summary is given of the investigations undertaken to det. the constitutions of Cr carbides by means of residual analysis. A new evaluation of these investigations disclosed the fact that Cr_5C_2, Cr_4C_2 and Cr_6C_2 are the prevailing carbide compds. The carbide of Moissan and Arnold and Read (cf. *J. Iron Steel Inst* **83,** 256(1911)), Cr_4C, could not be obtained by any other investigator. Two series of expts. were carried out with 0.5%, and 1.0% C, resp., and increasing Cr content from 0.5 to 30% Cr. The specific elec. resistance of the samples was measured by the method of Ebeling-Lindeck after annealing and after quenching at 950° in linseed oil. The results were plotted against the Cr content. The curves so obtained are similar to those of Edwards and Norbury (cf. *C. A.* **14,** 2328) with a break at 5% Cr; while this indicates the formation of a carbide M. and N. do not think it possible to develop, from the measurements of the specific resistance, the formula of the carbide in question. The diagrams developed for the systems Fe–Cr and Fe–Cr–C are discussed and numerous references given. The intersection of the Ac_1 and Ac_2 lines was found by extrapolation at 2 and 2.5% Cr. The diagram of Murakami was found to be correct with the exception that the boundary line inclosing the alloys capable of transformation is not at 0 but at 17% Cr. The dilation-temp. and the magnetism-temp. curves failed to give any indication as to the compn. of the carbides or to the presence of double carbides. J. A. SZILARD

British and American automotive steels. J. W. URQUHART. *Blast Furnace & Steel Plant* **16,** 906–8(1928).—Steels used by Ford are compared with those used by European manufacturers of the same class of car. The outstanding difference is in the chem. specifications resulting in less difficult heat treatment on parts in the American practice. J. W. BOECK

Metals and alloys used for bearings. ANTONY SETON. *Metal Ind.* (London) **33,**

29–30(1928).—The proper selection of suitable bearing metals is pointed out. Cast iron, chill cast iron and bronzes are discussed. The compns. of some bearing alloys are tabulated. J. W. Boeck

Magnetic properties of perminvar. G. W. Elmen. *J. Franklin Inst.* **206,** 317–38 (1928).—Perminvar is the name chosen for alloys in the Fe-Co-Ni series which, when properly heat treated, are characterized by "const. permeability over a considerable range at the lower part of the magnetization curve, small hysteresis loss throughout the same range of flux densities, and by a hysteresis loop constricted at the origin for medium flux densities." One of these alloys with a compn. of Ni 45, Co 25 and Fe 30% has a permeability about twice that of Fe, const. within 1% for fields less than 1.7 gauss. For a max. flux density of approx. 600 gauss the hysteresis loop has no measurable area although the corresponding loops for Armco Fe and Si-steel give 33 and 14 ergs per cc. per cycle, resp. Even when carried to higher flux densities, so that a measurable loop is obtained, coercivity is absent. This holds up to a max. flux density of 5000 gauss. Only when carried to 15,000 gauss does the loop resemble those for ordinary magnetic materials. Heat treatment modifies the magnetic properties in marked degree. *E. g.*, the initial permeability for a specimen "air quenched" from 600° is more than twice what it is for an otherwise identical specimen which has been "baked" for some time at 425°, although this difference decreases with increasing fields and disappears for fields above 50 gauss. In general, the rate of cooling dets. the hysteresis loss and the shape of the hysteresis loops Expts. with a compound rod, consisting of an unannealed piano wire core in a permalloy tube, suggest that the constricted hysteresis loop of perminvar may be due to a segregation in the alloy. This raises interesting questions as to the nature of ferromagnetism. A large no. of interesting curves and considerable numerical data are given. W. W. Stifler

The effect of the addition of chromium on the electrical properties of iron-nickel alloys. P. Chevenard. *Stahl u. Eisen* **48,** 1045–9(1928); cf. *C. A.* **22,** 752, 1752.—The effect of the addn. of Cr on the elec properties of Ni and Ni-Cr alloys is similar to the effect of Cr on the other characteristics of these alloys. The conclusions obtained previously by C. (cf. *C. A* **20,** 2813) and Ribbeck (cf. *C. A.* **21,** 557, 1085, 1958) are confirmed Cr extends the field of the austenitic Ni-Fe alloys toward the Fe field and reduces considerably the anomaly connected with the magnetic transformation, but causes a new anomaly "X" in the paramagnetic state. J. A. Szilard

Work performance and bending strength of high-speed steels. W. Oertel. *Stahl u. Eisen* **47,** 2036–8(1927).—The addn. of Co to high-speed tool steels contg. 0.7% C, 4.2–4.5% Cr, 17.0–18.4% W, and 1.3–1.9% V increases the cutting power very considerably, the best results being obtained with a high V content. Equally good results are obtained with W steels contg 2.9% Co and 1.9% V as with similar steels with 5.5% Co and 1.7% V. The max hardness combined with good elastic properties is produced by hardening at 1100–1200°. The bending strength of the steels hardened at 1025° falls to a very low value after tempering at 200°, rises somewhat at 300°, falls again at 400°, then rises rapidly with increase of tempering temp. to 600–625°, within which range the max. elasticity is obtained. B. C. A.

Principles governing the choice and utilization of permanent-magnet steels. R. L. Sanford. U. S. Bur. Standards, *Sci. Paper* **22,** 557–67(1927).—Magnet steels with a high Co content have coercive force values 2–5 times as great as those of the Cr or W steels generally used in the manuf. of permanent magnets, and the residual induction is only very slightly lower, but Co steels cannot be satisfactorily substituted for Cr or W steels without changing the design of the magnet. From tests of numerous types of magnet steels it is shown that the product of the coercive force and the residual induction is the best criterion of the value of a steel for this purpose. Magnet steels can be stabilized against permanent deterioration from transient demagnetizing fields by subjecting them to partial demagnetization; this method is particularly applicable to the treatment of Co steels because of their high coercive force. B. C. A.

Cast permanent magnets. J. Ferdinand Kayser. *Metallurgist* (Suppl. to *Engineer* **146,** No. 13) 136–8(1928).—Co-Cr magnets contain 10% Cr and 6 to 15% Co The relationship between coercive force and Co content is expressed by the formula $H_c = h + K_2Co$, where h is the coercive force of the Co-free base, Co the % of Co present and H_c the coercive force of the alloy. K_2 is approx. 7.5. In Co-Cr magnets made from rolled bars the same formula applies but K_2 = 5.5. Various types of such magnets are illustrated. D. B. Dill

Estimation of zinc pickup in hot galvanizing. E. D. Timmerman. Steel Co. of Can., Montreal. *Can. Chem. & Met.* **12,** 249–50(1928).—The application of the formula, $I = ak/m$, to estn. of the Zn pickup for washers, screws and square blank nuts

is illustrated. I = the percentage increase in wt. of the object after galvanizing; a = the surface area of the object in inches; m = the wt. of the object in lbs. after pickling and k = a const. for a given pickling plant. k is detd. for each pickling machine in the plant by exptl. detn., the objects being weighed before and after pickling and the surface area calcd. The value of k is variable between rather wide limits but in the shop the application of the formula affords a method of accounting and cost estn.

J. W. SHIPLEY

Obtaining a satisfactory zinc coating. WALLACE G. IMHOFF. *Iron Age* **122,** 811–4 (1928).—Factors affecting the quality of Zn for hot galvanizing and effects of Fe and Pb are noted. When no metallic addns. are made to the bath, the surface quickly oxidizes after a few days' operation. Spangles may be obtained, for a short time, with no metallic addns., but from a practical standpoint, pure Zn will not give a spangle due to rapid contamination with small amounts of Fe and rapid surface oxidation with resultant powdered luster. Pb is not harmful because it alloys with Zn only in small amounts and any excess Pb not alloying with Zn settles to the bottom of the pot. Cd tends to produce fine spangles, Al to give the coating a bright appearance and keeps down excessive oxidation of the Zn, Sn develops the large spangles on sheets and Sb, entering through the charging of scrap metal, tends to cause a brittle coating and a yellow discoloration if in too large amounts. Photomicrographs show the surfaces of high-Fe commercial slab Zn, of very pure commercial slab Zn and of pure rolled sheet Zn with total impurities less than 0.1%. W. H. BOYNTON

Notes on the hot tin-plating of wrought iron articles. EMILE BERTRAND. *Arts et métiers* No. **96,** 343–7(Sept., 1928).—Descriptive. A. PAPINEAU-COUTURE

A new process for spraying aluminum. F. A. LIVERMORE. *Metall* **48,** 89–91; *Chem. Zentr.* **1927,** II, 736.—Plant experiences of the firm Ludwig Löwe, Berlin, with the spray molding process are described. The description covers the compn. of the alloys, the properties required of the alloys, plant practice, and hints to the manufacturer of the castings. J. S. REICHERT

A new method of homogeneous lead coating. E. WASER. *Chem.-Ztg.* **52,** 719–21 (1928).—CO_2 under pressure at 350–400° is used in the Schoop spraying pistol to apply the Pb out of contact with O. J. H. MOORE

Alloy materials for boiler shells and tubes. J. B. ROMER AND W. W. EATON. *Power* **68,** 195–7(1928).—Locomotive tube sheets, side sheets and crown sheets are now commonly made from a Cu-Mo-Fe alloy called "Toncan" contg. 0.4% Cu and 0.05% Mo. This alloy resists corrosion and is similar to the best grade of low-C steel in phys. properties. Cr-Ni-Fe alloys resist corrosion and also retain their strength at high temp. A type analysis is C < 0.2%; Mn < 0.5%; P < 0.03%; S < 0.03%; Si < 0.5%; Cr 17–20% and Ni 7–10%. A typical alloy, *Enduro* 18–8, has the following phys. properties, hot rolled and annealed, resp.: *tensile strength,* 110,000, 90,000 lb per sq. in.; *yield point,* 82,000, 35,000 lb. per sq. in.; *proportional limit,* 67,500, 30,000 lb. per sq. in.; *elongation* in 2 in., 36, 61%; *reduction in area,* 52, 75%; *Brinell hardness,* 223, 135; *Rockwell hardness,* B-95, B-85. D. B. DILL

Value of aluminum and its alloys in chemical and allied industries. H. BUSCHLINGER. *Chem. Fabr.* **1928,** 209–11.—The corrosion of Al, as of other metals, is affected by cryst. structure and surface quality, the absence of inclusions (*e. g.,* Al_3Fe), and particularly by the quality of the water used if aq. solns. are being handled. The possibility of the application of Al to plant use in tar distn. is discussed. The penetration of the protective surface layer of oxide is often the decisive factor in starting corrosion. Large Al vessels should on structural grounds be cylindrical rather than hemispherical. The rapid diminution in strength with rise of temp. is pointed out. While the walls of vessels to withstand pressure are constructed on a theoretical basis the minor parts are usually designed according to empirical rules. In jacketed vessels the steam inlet must be designed to minimize mech. wear. In all cases corners and angles should be avoided to facilitate cleaning. With Al vessels which are to contain edible prepns., rollers, etc., should be used exclusively for Al, and the sheets should be pressed so as to give a smooth surface capable of polishing both inside and out. Suitable packing material, quite free from acid, should be used. B. C. A.

Mechanical properties of aluminum casting alloys at elevated temperatures. R. L. TEMPLIN, C. BRAGLIO AND K. MARSH. *Metal Ind.* (London) **33,** 179–82, 204–6(1928).—An abstract dealing with investigations carried out to ascertain the tensile strength of some Al casting alloys, and pure Al exposed at high temps. for short periods. The tensile properties at temp. ranges of 24–427° were emphasized with a few detns. outside of this range. Pure Al and low-Cu Al alloys show an appreciable effect of temp. on their mech. properties beginning at or near room temp. Alloys with higher Cu

content show little effect until temps. of 200–260° are reached. The alloys not following the general trend of the other groups in their behavior at the various temps. include essentially those that are susceptible to artificial aging or secondary heat treatment. When the tests of such alloys are made at or near the temps. corresponding to their aging temps. marked differences are observed in the test results. The "kinks" in the tensile-strength and yield-point curves for these alloys are almost eliminated by artificial aging of the specimens, at suitable temps., subsequent to the initial heat treatment. Multiplying the routine tensile strength figure at room temp. by 0.8 gives a value that introduces no serious discrepancies and may be considered in detg. the suitability of the various alloys for use at temps. between 24° and 427°. W. H. B.

Heat treatment of duralumin. Leslie Aitchison. *Fuels and Furnaces* **6**, 1191–4 (1928).—The heat treatment of duralumin necessary to produce the max. stress value is described. "As cast" duralumin possesses few mech. properties better than the binary alloys of Al. Quenched from a temp. of about 480° and aged for 5 days, duralumin possesses a max. stress of about 50,000 lb. per sq. in. Large castings should be machined before heat treatment as the quenching process is not so effective towards the center of a large casting. The desirable mech. properties diminish from the outside to the center of the metal. Age-hardening produces differential vol. changes in large castings tending to warp the metal. In small castings there is not sufficient difference in the rate of aging of the exterior and interior to cause warping. Castings should be machined as nearly as possible to finished sizes, before heat treatment, so as to reduce the ruling thickness of the metal to the min. J. W. Shipley

The causes of aging of the duralumin alloys. P. Ya. Saldau. *Ann. inst. anal. phys. chim.* (Leningrad) **3**, No. 2, 842–60(1927).—A review. G. B. Kistiakowsky

Observations on casting aluminum and its alloys. W. J. Clark. *Foundry* **55**, 847–9(1927).—A general discussion, with emphasis on cores, gates and pouring precautions. The higher shrinkage, the tendency to draw, crack and break on cooling, and frothing and drossing tendencies are noted. W. H. Boynton

Heat treatment of aluminum and its light alloys. VI. Discussion of defects of aluminum alloys due to heat treatment. Robert J. Anderson. *Fuels and Furnaces* **6**, 1035–6(1928); cf. *C. A.* **22**, 2912.—Improper procedure in quenching Al alloys may result in cracks, distortion, incipient melting, blistering and quenching stresses. Undue bumping or jarring during the transference of the pieces of metal, and too rapid cooling on quenching, must be avoided to prevent cracking or distortion. Heat treatment of alloys produces enhanced mech. properties. Al has a hardness of 15, while heat-treated Al alloys have a hardness above 150. The tensile strength of Al is about 12,000 lb per sq. in., while that of wrought Al alloys ranges from 34,000 to 80,000. J. W. Shipley

Aluminum brasses. Edmund R. Thews. *Can. Chem. Met.* **12**, 246–8(1928).—T. describes the heat treatment of Al brasses and reviews the metallurgical influence of the element as regards the casting properties of brasses. Al in brasses assists in fluxing the impurities and prevents drossing and fuming while conferring a high degree of fluidity on the melt. Up to 8% Al the tensile strength and elasticity of brasses increases but because of other deleterious properties imparted to the brass, percentages above 2 are undesirable. Up to 0.5% Al brass alloys can only be cold-rolled; at 1% the rolling and forging should not be above 140° F., while at 2% Al the brass may be rolled at dark red heat. Brasses contg. 33% Zn can only be hot-rolled when the Al content lies between 2.5 and 3.5%, while 60/40 brasses may be hot-rolled irrespective of their Al content. Quenching Al brasses produces brittleness. The order of alloying the constituents of Al brasses affects the mech. properties. Alloying the Cu and Al and then adding the Zn produces a "hard" metal. Al acts as an excellent deoxidizing agent and adds heat to the melt by reason of its higher heat of combustion. To prevent the inclusion of Al_2O_3 in the brass, pouring should be from the bottom of the melt. Al brasses are more resistant to corrosion than common brasses and are particularly useful to the ship-building industries. Iron in Al brasses imparts resistance to wear without affecting its strength and ductility. Tables relating the compn. of Al brasses to mech. properties are given. J. W. Shipley

The porosity and the physical properties of red brass. Reitmeister. *Warme* **50**, 526–30, 539–42; *Chem. Zentr.* **1927**, II, 1509.—There are 2 kinds of porosity, a so-called "outer porosity" which is characterized by the presence of large holes in the surface of the brass and another which is characterized by presence of small pores which are hardly or not at all visible to the naked eye (spongy porosity). This work deals with the inner porosity which arises from sepn. occurring when the alloy solidifies. The means of eliminating the spongy porosity and liquation are: the elimination of differ-

ences in temp. in the cooling brass, the shortening of the time of solidification of the alloy, and rapid cooling. The relation between chem. compn., liquation tendency and phys. properties of red brass and methods of testing are described. J. S. REICHERT

Recrystallization of α-brass with hot deformation. A. WITTNEBEN. *Z. Metallkunde* **20,** 316–22(1928).—The course of recrystn. in α-brass is studied by a systematic detn. of grain size, the alloys investigated are designated as Ms 90, Ms 85, Ms 73 and Ms 68; they contain approx. 90, 85, 73 and 68% Cu. They are subjected to a varying degree of deformation at 500°, 550°, 700° and 850°. The course of recrystn. is in general found to be the same as with soft Fe and Cu. Curves are plotted showing the relation of grain size to % deformation for the temps. used. Up to a definite degree of deformation, the grain size is unaffected, but above this point, a sudden change occurs due to recrystn. At higher temps. the grain size is apt to be larger than the original, while at lower temps. it is generally smaller. With a given alloy, recrystn. does not occur below a certain temp., regardless of the degree of deformation. This lower limit of temp. is 265° for Ms 90, 295° for Ms 85, 320° for Ms 73 and 330° for Ms 68. The original grain size has no influence upon grain size after recrystn., even with a difference in initial grain size of 2000%. The variation of recrystn. velocity with temp. is discussed. H. STOERTZ

The copper-magnesium alloys. III. W. R. D. JONES. Univ. College, Cardiff, Wales. *J. Inst Metals* **1928** (advance copy), No. 469, 11 pp.; cf. *C. A.* **21,** 3880.—Cu-Mg alloys contg. up to 10% Cu were forged and heat-treated, and tested for impact resistance at various temps. with a Charpy machine. With over 7% Cu the results at room temp. were variable, and the fractures were of a brittle type. Addns. of Cu up to 2% raised the impact value to 14 ft.-lb.; lower values were obtained with over 2% Cu in the forged alloys, and with over 5% Cu after heat-treatment. When kept 20 days at −7° and tested at that temp., the impact values of the tougher alloys were decreased, while those of the more brittle alloys were the same as at room temp. When tested at higher temps. up to 300°, the embrittling effect of Cu up to 8% was much decreased; with about 2% Cu impact values around 20 ft.-lb. were obtained at 200° to 300°. The forging temp. should be above 350°. The microstructures are illustrated and described. Forging broke up the Mg_2Cu network and caused the globules to be arranged in streaks. Quenching or air-cooling from about 460° increased the globule size, but did not improve the impact values GEO F. COMSTOCK

X-ray diffraction studies of copper alloys. JOSEPH LOISEAU. *Compt. rend.* **186,** 1732–3(1928).—After rolling and annealing, the Laue diagrams of pure Cu sheet and of 3 brasses: (1) Cu 67%, Zn 33%; (2) Cu 60%, Zn 40% (without Pb); and (3) Cu 60%, Zn 40% (with Pb) have been studied with the object of discovering the mechanism of recrystn. Annealing has the effect of orienting the (100) planes around an axis normal to the plane of the sheet. Overheating brings about reflections from the (110) (111) and (200) planes which are not evident under proper annealing conditions. A. J. KING

The influence of the addition of nickel to some copper alloys. HENGSTENBERG. *Metallborse* **17,** 1965–6, 2021–2, 2077–9; *Chem. Zentr.* **1927,** II, 2225.—Old and recent works of various investigators are cited to show the favorable influence exercised by a low percentage of Ni in Cu and Cu alloys. C. C. DAVIS

Mechanical properties of brass crystals. M. MASIMA AND G. SACHS. *Z. Physik* **50,** 161–86(1928).—A study was made of the behavior of small brass rods (73/27%) consisting of single crystals, over 80 mm. long. The observed phenomena are more complicated than those found in pure metals. The elec. conductance was within 1.5% the same in all directions but the measurement of the elastic properties (tension and torsion) showed that the rods were strongly anisotropic. The sp. extension α for a crystal the axis of which coincided with the cube-axis of a face-centered lattice was 3.5 times the value of α for a crystal oriented in the direction of the diagonal of a cube. The sp. torsion for these 2 extreme positions was in the ratio of 1:3. When the rods are stressed slip takes place, first on planes most favored with regard to the direction of applied stress until the orientation changes to a point where another system of slip planes becomes predominant. In highly symmetric orientations slip occurs in different parts of the rods along different slip planes. The beginning of slip occurs independent of the orientation at a tension of 1.44 ± 0.07 kg./sq. mm., in most cases without any hardening effect. Further deformation causes pronounced hardening. Slip in another direction becomes noticeable in the curves of tension *vs.* reduction in area by a sudden change of direction. The formation of the constrictions and fractures could not be satisfactorily explained. It was noticed, however, that the slip planes were strongly bent in the neighborhood of the fracture. H. S. v. K.

Heat treatment of drop-forged brass. R. Hinzmann. *Fuels and Furnaces* **6,** 1047–50, 1069–70(1928); cf. *C. A.* **21,** 3592.—In making drop forgings from brass bars some had perfectly smooth surfaces, while others made from the same bar had rough surfaces, showing cracks at the edges. An investigation was carried out to discover the cause of these differences. The variation in grain structure along the bar was found to be due to temp. differences during extension. The front end consists largely of needle-shaped α and β brass crystals while the rear end of the bar stretched at a lower temp. contains globular α and β grains. Annealing the bar did not give a uniform grain structure unless the temp. was kept above the crit. temp. of transformation, when on slow cooling the desired network of needle-shaped α crystals was obtained. Bars of different sizes subjected to the same annealing conditions gave brasses of different physical properties, due to varying grain formations within the metal. Annealing of globular α and β brass frequently results in a very coarse-grained metal. J. W. S.

The gold-platinum alloys. A. T. Grigor'ev. *Ann. Inst. platine* (Leningrad) **1928,** No. 6, 184–94.—G. has investigated the binary mixt. Au-Pt by means of thermal analysis, by studies of the microstructure and by measuring the hardness of the tempered alloys. He finds by all 3 methods that 2 solid solns. can be formed in the system: of Au in Pt with the limit of 20% by wt. of Au and of Pt in Au with max. 25% Pt. In the medium range of compn. a mech. mixt. of the 2 solid solns. is crystd. on cooling. The hardness was detd. according to Brinell (*Dinglers polytech. J.* **320,** 280(1905)). The hardness compn curve rises non-linearly up to 25% Pt, follows a linear section until 80% Pt, with a max. of 128.8 Brinell units at this last compn. and finally the curve drops again to the value of pure Pt of 26.0 units. G. B. Kistiakowsky

The constitution of the iron-tungsten and the iron-molybdenum alloys. Harry Arnfelt. *Iron Steel Inst. Carnegie Scholarship Mem.* **17,** 1–21(1928).—The binary Fe–W and Fe–Mo systems have been studied by means of x-ray analysis and it is shown that the equil. diagrams of these alloys hitherto suggested must be modified. A. concludes from his study of the Fe–W system that there are at least 2 intermediate phases present in this system, one of them having a hexagonal structure with a chem. compn. corresponding to the formula Fe_2W Another intermediate Fe-W phase has a trigonal lattice and crystals of this phase have been isolated and found to have a compn. corresponding to Fe_3W_2. In the Fe–Mo system there is an intermediate phase present that is analogous to the trigonal Fe-W phase. Crystals of this phase have a compn. corresponding to the formula Fe_3Mo_2. There seems to be no phase present in this system which corresponds to the hexagonal phase in the Fe-W alloys, but at a higher Mo content a new phase appears in the microstructure, which solidifies primarily. Possibly, if not probably, a third intermediate phase occurs in alloys comparatively low in Mo. Downs Schaaf

Lead-antimony alloys. W. Broniewski and L. Sliwowski. *Rev. métal.* **25,** 397–404(1928).—After reviewing previous work on Pb-Sb alloys, B. and S. give in tabular and graphical forms the results of numerous detns. of elec. cond., thermoelec. power, soln. potential, hardness, expansion coeff., m. p., solifying pt. and also results of micrographic examns. They conclude that these alloys are formed of 2 limiting solid solns. and their mixts., and that the anomalies observed both in earlier work and in the present measurements may be due either to imperfections in the methods used or to a change in the cryst. orientation of Sb. A. Papineau-Couture

X-ray analysis of the thallium-antimony alloys. Elis Persson and Arne Westgren. Univ. Stockholm *Z. physik. Chem.* **136,** 208–14(1928); cf. *C. A.* **22,** 3874.—Alloys of Tl and Sb ranging from 0 to 100% Sb were prepd. from pure metals. Powder x-ray pictures were taken with Fe-K radiation showing the existence of four phases: (1) α-Tl which, in the pure state, has a hexagonal close-packed lattice with the edge of the prism base equal to 3.449 A. U. and the height of the prism 5.513 A. U. (2) A phase with about 7% Sb, apparently a solid soln. of Sb in β-Tl, which has a face-centered cubic lattice with the parameter 4.842 A. U. (3) A second intermediate phase, corresponding to the compn. Tl_7Sb_2, which has a complicated cubic lattice. The parameter is given as 11.59 A. U. and the elementary cube contains 54 atoms. (4) Pure Sb, which has a face-centered rhombohedral lattice, the edge being 6.226 A. U. and the angle 87°24′. A. W. Kenney

A study of tin-base bearing metals. O. W. Ellis and G. B. Karelitz. *Metal Ind.* (London) **33,** 132–4, 156–8(1928).—A compilation of results of metallographic and mech. tests on a series of Sn-Sb-Cu alloys contg. up to 10% Sb and 8% Cu. Relationships between compn., microstructure, hardness and compressive strength of these alloys are given and the influences of elevated temps. and of Pb upon these properties are indicated. Two series of 25 alloys each were cast under varying conditions.

High-Cu alloys caused some trouble in pouring and the metal remaining in the crucible showed many large crystals of CuSn and a paucity of the Sn-rich matrix, while the portion flowing from the crucible contained few coarse crystals of CuSn and possessed an almost normal proportion of solid soln. Photomicrographs have indicated that the substitution of Pb for Sn in low-Cu alloys causes CuSn needles to crystallize in massive form, and the deleterious effect of Pb on malleability and shock-resisting qualities of certain of these alloys is due to the manner in which CuSn crystals sep. from the melt. A definite relation exists between the Brinell hardness numbers and the compressive strengths. High Cu content is undesirable with working temps. above 75°. The strength of these alloys falls appreciably with increased temp. within the working range of babbitts in bearings. Pb increases the mech. strength of babbitts, when used up to but 1%. At higher concns. the effect is entirely lost. The microstructural changes occasioned by Pb confirm the current opinion regarding its embrittling effect.
W. H. Boynton

Laboratory experiments on high-temperature resistance alloys. C. J. Smithells, S. V. Williams and J. W. Avery. Gen. Elec. Co., Ltd., Wembley, England. *J. Inst. Metals* **1928** (advance copy), 466, 22 pp.—Previous investigations of the Cr-Ni alloys are reviewed briefly. Alloys contg. 10 to 60% Cr, 40 to 90% Ni and 0 to 20% W or Mo were prepd. by fusing bars pressed from the mixed powd. metals and sintered together. Specially purified H was used to reduce Ni from the carbonate and a more pure electrolytic Ni was also used. Electrolytic Cr was treated with H to reduce oxides, and the melting was done in H. The alloys were cold-rolled and drawn to a diam. of 0.375 mm., with periodical annealing in H. With Cr up to 40%, cold working was easy; the alloy with 50% Cr could barely be drawn, and that with 60% Cr was glass-hard. The alloy contg. 40% Cr consisted of a solid soln., but with more Cr and less Ni a harder constituent appeared. With 20% Mo and low Cr a second phase also was found. A few photomicrographs of typical structures are shown. Methods of estg. the resistance to oxidation are discussed, and the method relied on was a life test of a 1-in. coil heated to 1100° by the passage of an elec. current. Alloys made with electrolytic Ni gave better results than those contg. more impurities. Intermittent heating gave much shorter life than continuous heating. Alloys contg. 70% Ni, at least 20% Cr and either with or without 10% W or Mo, gave the best results. The resistance to sag at high temp. decreased as the Cr or other alloy contents increased. Alloys with a duplex structure showed excessive sagging. By microscopic examn and x-ray analysis two types of oxides were recognized, protective contg. over 50% Cr_2O_3, and nonprotective with less Cr_2O_3. The lower Cr alloys showed chiefly the latter type. The elec. resistivities were measured at temps. up to 1000°, the app. used being illustrated and described, and the results plotted as curves. The latter show a max. or an inflection between 500° and 550°. The resistivities increased as the Ni content decreased; when W replaced part of the Cr, the resistivity decreased, but Mo had the opposite effect.
Geo. F. Comstock

Diseases of metals in museums. N. N. Kurnakov. *Ann. Inst. anal. phys.-chim.* (Leningrad) 3, 750–9; *Chem. Zentr.* **1927**, II, 2706.—Antique patina protects bronzes from further deterioration, whereas "wild" patina, which consists essentially of $3CuO.CuCl_2.4H_2O$, accelerates it. To remove the latter without injuring the former, the diseased bronze object may be boiled with Mg and water, whereby the following reaction occurs: $3CuO.CuCl_2.4H_2O + 3H_2 \longrightarrow 3Cu + CuCl_2 + 7H_2O$. A light coating of "wild" patina is removed by applying wadding impregnated with an alkali, heating gently (not over 300°) and drying.
C. C. Davis

Attack of iron and steels by the more important of the common acids. M. Sauvageot and (Miss) L. Lauprète. Schneider & Cie. *Chimie & industrie* Special No., 362–74(April, 1928).—Results are given in detail (in both tabular and graphic form) of corrosion tests carried out on a semi-hard steel (C 0.26, Si 0.41, S 0.043, P 0.059, Mn 0.54%) with H_2SO_4, HCl and HNO_3 at 15° and 45°, and in some cases at 0° and 80° also. A no. of tests were also made on an extra-mild steel (C 0.090%), a mild steel (C 0.083%) contg. 2.38% Ni, a mild steel (C 0.080%) contg. 0.642% Si, a mild steel (C 0.070) contg. 3.10% Si and a 12% Mn steel (C 1.14%). Conclusions: The rate of attack in H_2SO_4 increases with the concn. to a max. (corresponding to a concn. which is lower at high than at low temps.), then decreases rapidly and becomes very small at high concns. Gray cast Fe behaves like steel, but the concn. of max. corrodibility is lower than in steel. With HCl, the attack increases regularly with the concn. in both cast Fe and steel. With HNO_3 there is a range of low concns. in which the rate of attack of both cast Fe and steel increases with the concn., the range being approx. the same in both cases; but above this range the be-

havior of the 2 classes of metals is different. In steels for temps. below about 25° there is a zone in which the attack is variable, with irregular appearance of passivity, and which precedes the zone of true passivity; at higher temps. there is a zone of extremely violent attack, which reaches a max. and then falls rapidly to the zone of complete passivity. In gray cast Fe, max. attack occurs at a lower concn. than with steel and is followed at all temps. by a zone in which corrosion decreases progressively owing to the regular and increasingly rapid appearance of passivity, until the range of concns. of immediate passivity is reached. The above conclusions should not be generalized for all steels and cast irons, but S. and L. consider that on the whole they are applicable to the majority of annealed structural steels and for gray cast irons. A. P.-C.

The corrosive effect of water and its deacidification. Hermann Manz. *Wärme* **50,** 401–4, 416–9; *Chem. Zentr.* **1927,** II, 1382.—In continuation of his 1st article (*Ibid* **50,** 384–8(1927)), M. points out the important fact in practice that the excess-CO_2 ("corrosive CO_2"), estd. by analysis, is unimportant, if its quantity does not exceed 3.3% of the bicarbonate-CO_2 or 11% of the free CO_2. G. Schwoch

The phenomena of corrosion of iron and steel. A. Herrero and M. de Zubiria. *J. Iron Steel Inst.* (advance copy), No. **3,** 16 pp.(Sept., 1928).—Both the electrolytic and chem. theory of the corrosion of metals are discussed as well as some electrochem. phenomena. The causes producing corrosion are of 2 types: first, those which are independent of the object which suffers corrosion, and second, those which are a function of the phys. and chem. properties of the object. In the first classification are included: (1) atm. conditions in general, (2) degree of contamination of the air or water by gases, such as CO_2 which is very easily dissocd., or SO_2 gas which has a very intensive corrosive action, (3) stray currents from elec. circuits of high potential, (4) contact with other metals or with ferrous metals of different chem. compn., (5) faulty design. In the second group the following causes are mentioned: (1) local differences of compn. due to non-metallic inclusions, (2) deposits, local or otherwise, of foreign bodies, (3) segregation of metalloids, (4) internal stresses or strains. Also in *Foundry Trade J.* **39,** 239–40, 265–6(1928). D. S.

The resistivity of iron-copper alloys to acids and corrosion. S. S. Steinberg. Ann. inst. polytech. *Oural* **6,** 73–82(1927).—A comparative study has been made of the effects of H_2SO_4, HCl and HNO_3 and of the exposure to air on Fe-Cu alloys contg. from 0.13 to 1.21% Cu (0.10–0.14% C, 0.28–0.65% Mn, 0.021–0.060% P) and on ordinary sheet Fe (0.5% Mn, 0.07% C, 0.1% P, 0.012% Cu). H_2SO_4 (10 and 20% solns.) dissolves the alloys about $^1/_{10}$ as rapidly as it does the Fe. The action of HCl is about $^1/_2$ as rapid on the alloys. HNO_3 acts equally fast on both. Expts. on the rate of corrosion in air, although yielding somewhat erratic results, still indicate that the alloys show a greater resistance to corrosion than does the sheet Fe studied. The protective action of Cu is due to preferential soln. of Fe from the surface layer of the alloys, whereby the concn. of Cu in the surface is greatly increased. Thus, the expts. show that the full protective action of Cu is obtained only after about 24 hrs.' exposure to acids and that by mech. removal of this new surface the resistivity to acids can be decreased. G. B. Kistiakowsky

Material for grate bars. R. Stumper. *Arch. Wärmewirt* **8,** 335–6(1927).—S is not very injurious in grate bars, as they take it up in any case from the fuel. Photographs are given to show that oxidation takes place first at the boundaries of the graphite grains; hence a close structure is desirable. Ernest W. Thiele

Influence of copper on corrosion-resistance of steel and cast iron. R. T. Rolfe. W. H. Allen, Sons and Company, Bedford, England. *Iron and Steel Ind. and Brit. Foundryman* **1,** 205–8(1928).—A review. J. K. Roberts

Corrosion and the crystallite arrangement of rolled plate. R. Glauner and R. Glocker. *Z. Metallkunde* **20,** 144–7(1928).—Hot- and cold-rolled Cu plates were subjected to the action of HCl, HBr, H_2SO_4, CH_3COOH and mixts. of these with H_2O_2; also HNO_3, $HClO_4$, NH_3 and $(NH_4)_2S_2O_8$. The pieces were corroded in a rotating tester at const. velocity and temp. and examd. micro- and macroscopically. The influence of crystal orientation differed for different electrolytes. In some solns. the attack was more marked when there was no regular orientation and in others *vice versâ*. Both chem. and optical examns. must be made to det. the influence of crystallite arrangement on the corrodibility of metals. B. E. Roetheli

The protective action of sodium sulfate on the attack of ingot iron by alkalies and salts under high pressure. E. Berl and F. von Taack. Tech. Hochschule, Darmstadt. *Arch. Wärmewirt* **9,** 165–9(1928).—Tests 7.5 hrs. long were made on powd. ingot Fe in a bomb at 260–360°. After the test, alky. of the soln., loss of Fe and gain in O of the powder, and H_2 formed were detd. Up to about 0.02 *N* concn., NaOH

decreases the corrosion of pure water; above this the corrosion rises rapidly. When Na_2SO_4 is added in any amt. from 0.01 to 0.9 mol. per l., the corrosion for any concn. of NaOH remains below that for pure water. NaCl is weakly corrosive, and does not affect the action of NaOH. $NaNO_3$ evolves NO instead of H_2, and is moderately corrosive but inhibits NaOH to some extent; Na_2HPO_4 is more corrosive and a better inhibitor. Na_2S is very corrosive. Rontgen spectra show that the only oxides formed are FeO and Fe_3O_4. The effect of sulfate is perhaps due to the formation of a firm oxide film. ERNEST W. THIELE

Corroding action of solutions of various chlorides on cast iron and lead. B. K. PERSHKE AND G. I. CHUFAROV. Ural Polytech. Inst. *J. Chem. Ind.* (Moscow) **5**, 523–8(1928).—To det. the influence of the compn. of cast iron, 4 kinds were cut into plates and exactly weighed before and after their immersion in the salt solns. Of these 4 samples 1 was made by melting Fe with coke, whereas the other 3 were manufd from Fe and charcoal. The samples contained 0.0, 0.3, 0.41 and 0.89% Cr, resp. The aq. salt solns. used were those of KCl, $MgCl_2$ and NaCl, satd. and dil., pure and mixed. The detns. of the extent of corrosion were made while the following conditions were varied: access of light, satn. of the soln. by air, stirring of the solns., periodical removal of accumulated rust, etc. *NaCl solns.* have the max. corroding effect; *$MgCl_2$* has the minimum action; *KCl* is intermediate. It follows that sylvite solns. affect cast iron less than carnallite solns. Dil. solns. are generally more corrosive than satd. solns., the max. of corrosion having been attained with solns. of about 1% strength. Stirring of the solns. and their saturation with air treble the extent of the attack. Periodical drying of the samples increases the action of the solns. 1.25 times, whereas light increases it 1.7 times. The rate of corrosion remains unchanged with time. Cast iron is affected to the depth of 0.5 mm. annually under the most unfavorable conditions of action of the solns. The value of various *protective paints* was examd. A tar coating reduced cast iron corrosion to 1/5. *Lead* is attacked by solns. of chlorides 1/9 as much as cast iron, losing a layer of about 0.0065 mm annually. BERNARD NELSON

Lead as a protective coating for industrial chemical apparatus. A. JULIÁ SAURÍ. *Quim. Ind.* **5**, 117–21(1928).—A brief review of the resistance of Pb to chemicals and the 4 industrial processes of Pb plating: Schoop spraying, autogenous welding, direct deposition and electrodeposition. MARY JACOBSEN

Lead as a constructional material for chemical plant. S. J. TUNGAY. *Chem. Age* (London) **19**, 27–30(1928).—Among the valuable properties of Pb are: softness, plasticity, ductility, easily fused, cold worked by hammering, easily obtained pure, abundant and acid-resisting. Pb is serviceable for few acids other than H_2SO_4. It is perfectly resistant to cold dil. H_2SO_4 though it corrodes with 80% H_2SO_4, particularly when hot. Pb does not stand up to oleum or fuming H_2SO_4. "Chemical lead" is 99.99% pure. Five analyses of high-grade Pb are given of the quality over 99.67%. The purer the Pb the greater is the resistance to H_2SO_4. Cu sometimes nullifies the effect of Sb. Pb may contain inclusions of oxide which will produce porosity. Pb over 99.99% is best and an analysis is given of a Pb over 99.986% pure. Causes of failure seem obscure: repeated creeping and stretching nullify the protective coating on Pb which may then easily fail. The thickness of the protective corroded film depends on the velocity of flow of the corrosive material. Surface strains lead to corrosion. Concn. of liquid and the temp. affect corrosion. The presence of a salt of the metal in the corrosive liquid generally aids corrosion. NaCl in H_2SO_4 accelerates corrosion. Pb is used in phosphate, sulfonation and chlorination, $(NH_4)_2SO_4$ and nitroglycerin plants and in handling mixed acid. Vessels may be lined with Pb; a homogeneous lining is best. Hard Pb alloys are used for vessels, pans, frames, acid pumps, fans for acid gases, taps, ejectors and for plugs. Regulus metal must be made of Pb 99.9% pure and of Sb 99.5% pure; otherwise the castings may not be reliable. This alloy may contain 6–8%, 8–10% or 10–12% Sb. S. L. B. ETHERTON

The scope of corrosion-resisting steels in chemical engineering. T. H. BURNHAM. *Ind. Chemist* **4**, 320–4(1928).—The slowness with which the new corrosion-resisting steels are being introduced into chem. plant is due principally to the complexity of the problems of corrosion. The alloy steels discussed range from 10 to 30% Cr and 7 to 40% Ni, with an Fe content of from 50 to 70%. The most useful are found in two sep. ranges, one contg. 18–25% Cr with 7–10% Ni, the other contg. 10–15% Cr with 30–40% Ni. Other elements such as Si, Cu, W or Mo may also be present. The physical and mechanical properties of "Era C. R." steel are given, also the proper heat treatment and method of descaling. All these steels can be readily machined and welded. "Era C. R. 3" is not appreciably attacked by dil. H_2SO_4. All will resist corrosion by fermentation products including AcOH. The Ni-Cr steels are resistant

to HNO_3 and to HNO_3 + H_2SO_4. Several grades are suitable for milk cans. Steels may also be obtained which are resistant to dil. H_3PO_4, boiling fruit juices, to most of the solns. in the manuf. of artificial silk, to dye-house liquors, to the liquors encountered in refining fats and oils, to $FeSO_4$ soln, to filter alum, to NH_3 and to various salts. "Era H. R." can be used for NaOH fusion and molten $NaNO_3$ up to 700°, for high-pressure work (*e. g.*, Bergius hydrogenation of coal), for petroleum-cracking plants and for high-pressure steam generation. "Hecla A. T. V." steel has been successfully used in a turbine operating with steam at 800° F. for long periods. E. G. R. A.

The application of aluminum, steel, VA-metals and iron-silicon alloys in nitric acid manufacture. III. Iron-silicon alloys. BRUNO WAESER. *Chem. Fabrik* **1928,** 544-5.—Review from the literature of the compn, physical properties and corrosion resistance of commercial Fe-Si alloys made in all countries. The trade names of the metals discussed are Neutraleisen, Acidur, Agdiron, Esilit, Thermisilid, Antacid, Wegucid, Kiesel, Duracid, Elektrosilit, Superneutral, Elianit, Tantiron, Duriron, Corrosiron, Ironak, Narki, Delhi, Cyclops No 17 and Silicrome. G. B. TAYLOR

New methods of corrosion testing. J. CZOCHRALSKI AND E. SCHMID. *Z. Metallkunde* **20,** 1-7(1928).—Heat-treated and cold-worked Al and Cu and cold-worked brass wire were immersed under tension in corroding media consisting of 30% NaOH, 7.5% HCl and 2.5% $CuCl_2$ for Al; 25% HNO_3, 10% $(NH_4)_2S_2O_8$ and 8.3% $CuCl_2.NH_4Cl$ + NH_3 for Cu; and 17% HCl for brass (Cu 57.9%, Zn 40.4%, Pb 1.7%). The temps. were 20° for Al and Cu and 50° for brass. Curves of time *vs.* breaking load and extension data are given. The breaking loads and extensibility decrease with time of immersion. Brass is dezincified in HCl. The dezincification uniformly progresses to the center of the wire Breaking loads predicted from analyses of corrosion products are in most cases higher than those actually observed, showing that the attack is not all on the surface of the metal, but also occurs between crystals. The smallest discrepancies were observed in NaOH; the largest in $CuCl_2$. Hard Al was less rapidly attacked than the heat-treated metal, while the reverse was noted in Cu. $(NH_4)_2S_2O_8$ caused the greatest discrepancies in the soln of Cu. Dezincification of β-brass preceded that of the α-metal. It is concluded that measurements of loss in wt. and of diam. decrease do not give adequate information regarding the changes in mechanical properties of corroded metals. B. E. ROETHELI

Oxidation of iron in water by the action of oxygen and carbon dioxide. N. M. GAVRILOV, S. K. MEL AND P. K. MEL. *J. Chem. Ind.* (Moscow) **5,** 697-700(1928).—The *mechanism of Fe corrosion* is believed to be as follows: (1) The surface of Fe being mechanically or chemically freed of oxides, the metal immediately becomes covered by a film of the lower oxide on contact with air in presence of water; (2) after a while the oxidation goes further with formation of $Fe(OH)_3$; (3) then the adhering film of $Fe(OH)_3$ is gradually reduced by the adjacent Fe with simultaneous oxidation of the latter, (4) By the action of water satd. with CO_2 on metallic Fe the following 2 reactions take place: (*a*) rapid soln of low oxides which are on the surface of the metal, and (*b*) slow soln. of Fe in CO_2; (5) Fe $(HCO_3)_2$ which dissolves is oxidized by O to $Fe(OH)_3$, this reaction being favored by the decrease of partial O pressure and by the temp. increase; (6) after remaining for a long time under a $Fe(HCO_3)_2$ soln. and being subjected to the action of the gas Fe becomes quasi-passive, but vigorous shaking detaches the film of oxides from Fe and the activity of the metal is restored; (7) if gases with a high O content (5%) are blown on to Fe covered with water, the metal surface becomes covered with insol. oxides while the expt is still under way, and the concn. of Fe in the soln. is lowered; (8) the most favorable conditions of Fe corrosion are attained in operating with a gas contg. not more than 5% O and not less than 14-15% CO_2, the temp. being low; in case of a drop of concn of $Fe(HCO_3)_2$ in the course of the operations the activity of the Fe can be restored by leaving it for some time under fresh water.

BERNARD NELSON

The use of aluminum in the manufacture of equipment. H. BACH. *Metallborse* **17,** 985-6, 1044-5, 1100-1, 1157, 1213-4, 1269, 1380-1, 1491-2, 1547-8; *Chem. Zentr.* **1927,** II, 1075-6.—A report on the corrosion of sheet Al by "activin" (no corrosion under practical conditions), aqua ammonia (strong corrosion), NH_4 compds. (of those investigated NH_4Cl solns. are most corrosive), "antiformin" (highly corrosive even in dil. soln.), dil. HNO_3 and mixts. of HNO_3 and H_2SO_4 without H_2O (Al is more resistant to dil. KNO_3 than brass, while with the other corrosive mixts. Al lies between Cu and brass), beer and soda water (no corrosion), chloride of lime solns. (considerable corrosion with a 0.4% soln.), K_2CrO_4 and $K_2Cr_2O_7$ solns. (no corrosion with 1-10% solns. neither cold nor hot), chromic acid (corrosion increases with concn. and temp.), acetic acid (the cold acid attacks soft annealed samples less than hard annealed samples,

while the hot acid frequently attacks the soft annealed samples more), formaldehyde and furfurole (slight corrosion with hot formaldehyde, no corrosion with either hot or cold furfurole), tanning solns. (no action), hanging in greenhouses (no action), Glauber's salt and K salt solns. (only slight reaction), CaC_2O_4 (strong reaction), copal (no reaction in contrast with Cu), $CuSO_4$ and $ZnSO_4$ solns. (strong reaction), lysol (no reaction at room temp. and only a slight reaction at 60–70°), lactic acid solns. (no reaction with dairy products since their lactic acid content is too low), Na_2SO_4 (slight reaction), oxalic acid solns. (no reaction with low concns. in the cold, very considerable reaction with higher concns. when hot), ozonized air (no reaction), phosphoric acid solns. (corrosion increase with increasing acid concn.), salicylic acid (the dry acid does not attack Al, when moist it reacts in the cold after a long time), nitroglycerin (no attack), explosives (confirmation of the favorable behavior with nitroglycerin, relatively slow reaction with 104% oleum and a much more rapid reaction with weaker H_2SO_4), cabinet makers' glue (no reaction), transformer oil (no reaction), $ZnCl_2$ solns. (do not corrode Al as much as Fe), citric acid solns. (very slight reaction in the cold, appreciably more when hot), sugar and its sources (losses in wt. are influenced mechanically; chemical action is considerable when Al comes into contact with limed liquors, neutral liquors induce practically no change). J. S. REICHERT

The corrosion of metals and of light metals by motor fuels. SCHMIDT. *Auto-Technik* **16,** No. 51, 7–9; *Chem. Zentr.* **1927,** II, 1615.—Expts. were carried out on the corrosive action of benzine, C_6H_6, 96% EtOH and 50·50 and 30:70 C_6H_6-EtOH mixts. on steel, Cu, brass, Al, duralumin, Mg and riveted combinations of these metals to det. a satisfactory protective material for fuel tanks. EtOH and EtOH mixts. were the only fuels which corroded all the metals. If there was no effect after 24 hrs., there was none after 6 months. In a further discussion, the influence of water (without which benzine does not mix with EtOH), the harmful results of using metals of different potential, the extensive corrosion of Pb-lined tanks with C_6H_6, and of tinned tanks with EtOH, and the importance of detg. the purity of fuels and the absence of certain compds. are all emphasized. C. C. DAVIS

The corrosion of aluminum. C. PROKEŠ. *Chemický Obzor* **1,** 349–58; *Chem. Zentr.* **1927,** II, 974.—The corrosion of Al by H_2O, inorg. and org. acids, halogens, org. and inorg. halogen compds., as $FeCl_3$, NaCl, $SnCl_2$, $(CH_2Cl)_2$, $Cl_2C:CHCl$, etc., is discussed. The influence of lyes, NH_4 salts, Me_2CO, C_2H_2, alkaloids and alcs. is described. G. SCHWOCH

External corrosion of copper and brass service pipe. K. H. LOGAN AND S. P. EWING. *J. Am. Water Works Assocn.* **20,** No. 3, 390–403(1928).—A preliminary report. After being buried two years, inspection showed the test pieces well able to stand such exposure. Where steel, Cu, or brass were in contact there was little indication of galvanic action. D. K. FRENCH

Cause of the corrosion and destruction of zinc coating galvanizing pots. WALLACE G. IMHOFF. *Am. Metal Market, Mag. Sect.* **35,** No. 179, 1–6, 16(1928).—Rapid corrosion of a galvanizing pot is usually due to too high a temp. The dissolving power of molten Zn for Fe is low up to 900° F., but rapidly increases above this temp. The proper temp. for galvanizing lies between 840° and 885° F. Pure iron pots are more resistant to corrosion at high temps. than steel. Increase in the Si content of the steel favors corrosion while increase in the C, Mn and P content has no effect. The Fe-Zn alloy formed at high temps. is non-ductile, non-coherent, non-malleable and readily breaks up into small crystals which float off into the molten Zn, exposing a fresh surface of the pot to the alloying action of the Zn. The development of the alloy crystals is from the boundaries toward the center, forming hexagonal crystals. The higher the temp. the larger are the crystals. J. W. SHIPLEY

Investigations of the action of alkalies and various salts on iron. K. TAUSSIG. *Arch. Wärmewirt.* **8,** 337–40(1927).—A critical résumé of the work of Berl, Staudinger and Plagge (*Ver. deut. Ing. Forschungsarbeiten* **295** (1927)) on the action of solns. on Fe at high temp. and pressures. ERNEST W. THIELE

The chemical bases for the inoxidation processes. Thermal, gas-analytical and metallographical results. E. PIWOWARSKY. Tech. Hochschule, Aachen. *Giesserei Z.* **15,** 177–80(1928).—Objections to the investigations of others, due to the use of old inoxidation ovens, are eliminated in this investigation. Good inoxidation is obtained by annealing 2.5–3 hrs. at 800–880°. At and above 900° defective spots develop. Gas analyses give no rule for detg. the best gas compn. for inoxidation. Much more O_2 is consumed for the formation of the inoxide during the oxidation process than during the reduction. The oxidation appears to be greatly influenced by the amt. of H_2 in the gas phase. Microscopic examn. shows that an inoxide film consists of (1) an outer

zone, probably Fe_3O_4, made up of a bright, homogeneous, non-metallic material, and (2) an inner zone, assumed to be FeO, consisting of a bright zone (similar to the outer) cut or surrounded by a darker net-work. The latter forms a good binding material between the protective outer layer and the metal. With increase in the duration of the annealing, the thickness of the outer zone and the amt. of bright material in the inner increases, until finally they disappear entirely. The limits of the film thickness are 0.12–0.065 mm., the usual thickness being 0.085–0.075 mm. The thickness depends on the C content of the material and on the length of treatment. Both cast and wrought Fe inoxidize well; under similar conditions, however, the outer zone of the inoxide film of the latter is more homogeneous and thicker. With longer times of annealing, specimens which are not heavily rusted may be inoxidized well. J. B.

Granjon, R. and Rosemberg, P.: **Traité de soudure autogène et d'oxy-coupage.** Paris: Publications de l'Office Central de l'Acétylène et de la Soudure Autogène. 320 pp.; F. 15. Reviewed in *Chimie et industrie* **20**, 595(1928).

Weinig, Arthur and Palmer, Irving A.: **The Trend of Flotation.** 2nd ed. revised. Golden, Colo : Colorado School of Mines. 90 pp. Reviewed in *Eng. Mining J.* **126**, 354(1928).

Steel alloy for permanent magnets. E. Pakulla. U. S. 1,661,907, March 6. High-speed steel contg. Cr and at least one of the elements W, Mo or Co is heated (suitably at about 1100–1150°) at a temp. above lowering temp., and is quenched in oil or other mild non-aq. hardening agent.

Mineral flotation. Arthur H. Fischer (to Guggenheim Bros.). U. S. 1,684,536, Sept. 18. Flotation is effected in the presence of a water-repellant reaction product of a metal xanthate and an acid chloride, *e. g.*, the reaction product from K ethyl xanthate and ethyl chlorocarbonate, acetyl chloride, $COCl_2$ or SO_2Cl_2.

Froth-flotation ore concentration. Rhetherford B. Martin (to Minerals Separation North American Corp.). U. S. 1,686,529, Oct. 9. A suitably ground sulfide ore pulp which may contain Zn as found in Butte and Superior ore is agitated with a mineral-frothing agent such as pine oil and K xanthate and with a compd. of aniline or benzidine with $CuCl_2$ or other suitable org. compd. carrying N and Cu and capable of assisting in the selective flotation. Cf. *C. A.* **22**, 3386.

Ore concentration by flotation. A. H. Fischer (to Guggenheim Bros.). Brit. 284,198, Jan. 24, 1927. Flotation is effected in the presence of a product of reaction between a metal xanthate and an acid chloride which may be dissolved in oils such as kerosene and used in an acid or alk. flotation circuit in the presence of frothing agents such as cresylic acid or pine oil. K ethyl (or Am, Bu, Pr or aryl) xanthate may be acted on by ethyl chlorocarbonate in the presence of alc. or by AcCl in the presence of CCl_4 or by a soln. of $COCl_2$ in toluene or by SO_2Cl_2 in the presence of alc. to form the xantho compds.

Concentrating oxidized ores and minerals. Frank A. Bird. U. S. 1,686,064, Oct. 2. In order to render oxidized ores such as those of Pb, Zn and Fe amenable to flotation concn., the ore is ground in a mill free from metal surfaces likely to contact

with the ore, and is then subjected to the action of a sulfidizing agent to form a film of sulfide on the ore particles.

Briquetting and reducing sulfate minerals. JAMES E. BOOGE and JOSEPH P. KOLLER (to E. I. DuPont de Nemours & Co.). U. S. 1,685,772, Oct. 2. A powd. sulfate ore such as barytes contg. more than 4% of silica is formed into tablets or briquets with coal and a binder such as waste sulfite liquor which depends upon its coking properties for its binding action, and these tablets or briquets are heated to produce sulfide.

Apparatus (with a reciprocating table) for concentrating ores. MERLE M. NEWTON. U. S. 1,685,644, Sept. 25.

Centrifugal apparatus of the vertical type for concentrating and amalgamating placer gold, etc. FRANK D. LEWIS. U. S. 1,684,870, Sept. 18.

Centrifugal ore separator. EDDIE H. STEPP. U S. 1,685,466, Sept. 25.

Magnetic ore separator. WM. L. MCADAMS. U. S. 1,686,917, Oct. 9.

Roasting and sintering ores. COMPAGNIE DES METAUX OVERPELTLOMMEL. Brit. 284,248, Jan. 26, 1927. Ore or similar material is brought to a suitable S content and then moistened and compressed, with or without a binder such as org. material or $FeSO_4$ or H_2SO_4, then fed through an extrusion press for production of threads which break into small grains; the latter are dried and sifted, and then roasted as a thin layer or sintered on the grate of a blast app. App. is described.

Open-pan sintering apparatus (with tiltable pans) for sintering ores. P. ANDERSON. Brit. 284,793, Nov. 9, 1926.

Treating metal-bearing residues. M. MEYER and L. MEYER (trading as Huttenwerke Tempelhof A. Meyer). Brit. 285,462, Feb. 17, 1927. Residues contg. Sn, Sb, Pb and Cu as oxides are treated with dil. H_2SO_4 to remove the Cu as sulfate; the $PbSO_4$ formed is mainly removed as chloride by use of hot chloride solns., and the residue is melted with caustic alkali and alkali chloride to produce a mixt. of alkali stannate, plumbate and antimonate. By lixiviation with water the antimonate remains as a residue, and Pb may be pptd. as PbS from the soln. obtained. Brit. 285,463 specifies treating residues contg. Sn, Sb, Pb and Cu partly as oxides and partly in metallic form by melting with caustic alkali and alkali chloride, sepg. the unchanged metal as a regulus, and further sepg. the stannate, antimonate and plumbate formed by lixiviation and pptn. treatments, and finally converting the Cu oxide residue obtained into sulfate.

Briquetting powdered iron ore or concentrate. P. GREDT. Brit. 285,040, Feb. 9, 1927. The raw material is mixed with powd. coke, semi-coke, coal or charcoal, crushed reduced ore and with material such as $MgCl_2$ or HCl which forms an oxidized compd. or salt with the reduced raw material.

Iron from ore. VEREINIGTE STAHLWERKE A.-G. Brit. 284,991, Feb. 7, 1927. Ores are treated with Cl or Cl-contg. substances such as vaporized HCl to form $FeCl_3$ and the $FeCl_3$ is then reduced at a temp. of 300–500° with H. The chlorination may be facilitated by use of pressures above 10 atm. and, before reduction, the $FeCl_3$ is freed from water. Spongy Fe may be added to serve as a catalyst in the reduction and oxide remaining in the product may be returned for further treatment after a magnetic sepn. of the Fe. $MgCl_2$ or NH_4Cl also may be used in the chlorination, and a preliminary treatment with Cl or HCl at 100° may be applied to the ore to remove As or Sb from ores contg. them.

Apparatus for recovery of metal values, etc., from fumes such as those produced in zinc smelting. MORTON I. DORFAN (to Allis-Chalmers Mfg. Co.). U. S. 1,685,229 Sept. 25.

Smelting apparatus (with a centrifugal extractor) suitable for the treatment of ores of mercury or tin. CHARLES E. GLESSNER. U. S. 1,686,912, Oct. 9.

Cyanide process. SIBLEY B. MCCLUSKEY. Can. 283,696, Oct. 2, 1928. Precious metals are sepd. from their ores contg. cyanicides, by crushing the ore in cyanide soln., expelling substantially all the cyanide from the pulp in the form of HCN gas, pptg. the cyanicides in alk. soln. and restoring expelled gases to the pulp in the presence of an excess of alkali. Cf. *C. A.* **22,** 2544.

Precipitating heavy metals from ammoniacal solutions. CARL MÜLLER, LEO SCHLECHT and WALTER SCHUBARDT (to I. G. Farbenind. A.-G.). U. S. 1,686,391, Oct. 2. Solns. such as those contg. Ag and Cu are treated with a reducing gas, *e. g.*, water gas, while heated and under pressure to effect practically complete pptn. of the metals such as Ag and Cu. Ni, Co and Zn are also mentioned.

Melting and refining copper. HARRY H. ALEXANDER. U. S. 1,687,277, Oct. 9. Hot combustion gases are impinged against the surface of a charge of hot Cu and the Cu is progressively melted while subjected to a purifying atm. which is controlled by

regulating the quantity of air and fuel used in formation of the combustion gases, in accord with the nature and compn. of impurities present in the Cu (which may be removed by oxidation); this regulation is based on periodic detns. of the character and quantity of the impurities in the Cu. An app. is described.

Refining and casting copper. Copper Deoxydation Corporation. Fr. 635,673, May 24, 1927. In the treatment of Cu it is kept out of contact with combustion gases and reagents are added to eliminate S, O and H. The Cu is preferably heated electrically.

Refining lead bullion. George K. Williams. U. S. 1,687,188, Oct. 9. See Brit. 267,104 (*C. A.* **22,** 1129). U. S. 1,687,187. See Brit. 267,105 (*C. A.* **22,** 1129).

Purifying lead. Wilbur H. Judy (to Sumet Corp.). U. S. 1,686,277, Oct. 2. H (with exclusion of O) is introduced into the mass of molten metal, to remove S and render the Pb suitable for alloying with Cu and Sn.

Lead and zinc extraction. Friedrich Johannsen (to Fried. Krupp Grusonwerk A.-G.). Can. 283,425, Sept. 18, 1928. Pb and Zn are extd. from Pb-Zn ores by treatment in 2 sep. working stages, in which the materials are rolled around or tumbled about in a furnace, the Pb being first volatilized under purely oxidizing conditions, the residue from the oxidizing process being then submitted with reducing agents to a further process of volatilization, the gaseous products of the two processes being collected separately, so that a Zn-free Pb product and a Pb-free Zn product are obtained.

Working zinc. Walter M. Towne (to E. W. Bliss Co.). U. S. 1,686,353, Oct. 2. In forming cups or similar Zn articles the metal is pressed between dies and extruded through an annular opening at temps. of 150–300°.

Metallic thorium. Wm. B. Gero (to Westinghouse Lamp Co.). U. S. 1,685,915, Oct. 2. In compacting Th or similar rare refractory metals, the metal while in a coherent state is subjected to pressure and the flow of the metal while being pressed is subjected to a yielding restraint, *e. g.*, by use of a surrounding body of soft metal such as Pb, Al or Cu during the pressing.

Uniting ferrous and cuprous metals. Willis R. Whitney (to General Elec. Co.). U. S. 1,685,657, Sept. 25. The regions to be joined, while pressed together, are brought into contact, in a reducing gas, with a molten alloy of Cu and Ag. The process is suitable for use in joining Cu cooling fins to cylinders of air-cooled engines.

Castings. Vereinigte Stahlwerke A.-G. Fr. 635,907, June 13, 1927. Castings of high quality are obtained by allowing the crude casting to solidify as white cast iron in casings instead of sand and artificially cooling by means, for instance, of a spray of water. Cf. *C. A.* **22,** 1754.

Casting metal articles such as pistons in permanent molds. Harry S. Lee. U. S. 1,685,545, Sept. 25. In making pistons or other castings a mold is used having walls with locally thickened portions to "choke back the heat" and reduce the heat cond. at these portions of the mold. U. S. 1,685,546 specifies regulated application of a cooling fluid to certain portions of the exterior of the mold.

Casting chilled rolls. C. O. J. Broms. Brit. 284,337, Jan. 29, 1927. Various details of a casting operation are specified, in which a non-chilled portion of rolls is cast after a suitable thickness has solidified in the chill mold.

Centrifugal casting of iron pipe or other cylindrical metal bodies. Michael C. Smotzer and John A. Byers (to James B. Clow & Sons). U. S. 1,684,419, Sept. 18. Mech. features.

Casting articles of "corrosion-proof" steel. Friedrich Hauptmeyer (to Fried. Krupp A.-G.). U. S. 1,684,700, Sept. 18. The steel to be melted is embedded in a receptacle and covered with a deoxidizing flux, and is melted down and cast through a closed channel in a closed mold. The walls of the receptacle, channel and mold are formed of material such as clay which is free from C and the charge is melted by an open flame.

Apparatus for casting metals under pressure. Erik Jorgen-Jensen. U. S. 1,684,994, Sept. 18.

Apparatus for making castings under pressure in a plurality of molds with a single pressure-casting machine. S. Junghans. Brit. 284,256, Jan. 26, 1927.

Apparatus for casting bell-flanged pipe, etc. William H. Millspaugh (to Paper and Textile Machinery Co.). U. S. 1,686,624, Oct. 9.

Alloy surface for castings. Roger Williams (to The Electro Metallurgical Co. of Can., Ltd.). Can. 283,748, Oct. 2, 1928. A mold for steel or Fe castings is coated to 1/8 of an in. while green with comminuted Cr contg. 2.0% of NaF and a binder (such as linseed oil, molasses, etc.). The mold is dried and baked to 600–700° F.; the coating

hardens and adheres to the surface of the mold. The metal is then poured into the mold and casting made.

Sand mold for casting magnesium, etc. GILBERT MICHEL (to Hart O. Berg). U. S. 1,685,553, Sept. 25. Sand for prepg. molds is incorporated with a soln. of rosin in a hydrocarbon oil or other suitable non-aq. oily vehicle and $C_{10}H_8$.

Preparation of cores and molds for metals from liquid-hardening material. CYRILL AUER. Austrian 109,181, Nov. 15, 1927. The cores or molds are cast from a mixt. of water, gypsum, sand and S which is filled into a mold and compressed to remove the excess of water.

Chromium coating for castings. WALTER M. MITCHELL (to The Electro Metallurgical Co., of Can., Ltd.). Can. 283,747, Oct. 2, 1928. A mold for steel castings is coated while green to a depth of $^1/_8$ of an in. with coarse comminuted Cr (15 to 40 mesh) mixed with a binder (silicate of soda soln.). When the coat has set, but before being baked, a second coat of $^1/_{16}$ of an in. of comminuted Cr (80 to 100 mesh) mixed with a binder to form a paste is applied to selected portions of the mold, which is then dried and baked. This second coat prevents denuding the selected portions during pouring of the casting metal. Cf. *C. A.* **22,** 3387.

Copper coating on stereotype plates. COLBY C. WALLER. U. S. 1,684,565, Sept. 18. A fibrous blank is impregnated with an emulsion contg. $CuSO_4$, hydrous Al silicate, boiling water and gum arabic, the matrix is impressed with the desired characters at a temp. of about 115°, molten type metal is cast against the matrix and the casting is removed and cleaned.

Sound ingots. KOTARO HONDA. Fr. 635,942, June 14, 1927. The fused metal is poured into an iron mold, almost to the top, and melted slag is afterwards poured into a raised portion placed on the mold as soon as possible after the metal has been poured, to furnish a supplementary source of heat and pressure to the top of the ingot.

Soaking pit. HERBERT C. RYDING. Can. 283,823, Oct. 2, 1928. A soaking pit for heating ingots.

Bearing metal. EUGEN VADERS. Can. 283,721, Oct. 2, 1928. Alloys for use as bearing metals contain Cu 78.5–92.8, Al 5–9.5, Mn 1–6, Fe 0.1–3 and Ni 0.1–3%. Cf. *C. A.* **21,** 888.

Porous metals for bearings, etc. GENERAL MOTORS RESEARCH CORP. Brit. 284,532, June 15, 1927. Metals which do not completely alloy together are heated with graphite and another de-oxidizer; *e. g.*, a suitable mixt. may be formed of Cu 90, Sn 8, Pb 10, phosphor-Sn 2, graphite 6 and salicylic acid 2–4 parts.

Refractory metals. NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 284,990, Feb. 7, 1927. In a process such as is described in Brit. 200,879 (*C. A.* **18,** 374) the atm. employed contains N in addn. to the volatile metal compd. An app. is described in which W wire may be treated with N and WCl_6 which may be heated by a bath of mixed K and Na nitrates.

White metal. OSKAR GRÜNBAUM. Austrian 109,161, Nov. 15, 1927. A white metal comprising Pb, an alkali metal and Zn contains up to about 5% of alkali metal and an amt. of Zn equal to 0.47–1.5 times the amt. of alkali metal.

Centrifugal apparatus for continuous mixing of finely divided metals with other pigment materials, etc. M. RAGG and F. RAHTJEN. Brit. 284,172, Oct. 1, 1927.

Gas furnace for reducing ores. LUIGI BAROSSO. Ital. 249,911, June 22, 1926.

Metallurgical furnace suitable for melting metals. HOWARD BUTT (to Riley Stoker Corp.). U. S. 1,687,470, Oct. 9.

Vertical shaft furnace for producing metals or alloys from finely divided ores. D. CROESE. Brit. 284,459, Jan. 20, 1927.

Furnace for heat-treatment of sheet metal, etc. JOSEF HIRSCHMANN (to Eastern Rolling Mill Co.). U. S. 1,686,696, Oct. 9.

Blast furnace charging apparatus, etc. FREDERICK H. WILLCOX (to Freyn Engineering Co.). U. S. 1,685,208, Sept. 25.

Checkerwork construction for open-hearth and blast furnaces. FRED H. LOFTUS. U. S. 1,686,826, Oct. 9.

Rotary furnace suitable for calcining processes. ERNST AMME, KARL DIENST and DAVID J. UHLE. U. S. 1,685,972, Oct. 2. Stuctural features.

Rotary furnace for roasting pyrites, etc. METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 284,731, Feb. 4, 1927. The furnace is divided into a plurality of compartments by transverse partitions carrying ribs, projections or guide members which serve to scatter the ore and to bring it into more intimate contact with the roasting air. Various structural details are described.

Cast iron. WERNER STAUFFER. Fr. 635,811, June 11, 1927. A cupola of cast

iron of superior quality and slightly carbonized is made from a melt contg. more than 30% steel and less than 50% crude cast iron and pieces of cast iron, with additions of Si and Mn. The blast is regulated to any desired quantity between 80 and 120 cu. m. per min. for each sq. m. of cupola.

Foundry iron. FRIED. KRUPP A.-G. Fr. 635,924, June 13, 1927. See Brit. 274,035 (*C. A.* **22,** 1946).

"Synthetic" pig iron. EMIL EDWIN (to Aktieselskapet Norsk Staal (Elektrisk-Gas-Reduktion)). U. S. 1,686,075, Oct. 2. See Can. 283,386 (*C. A.* **22,** 4102).

Wrought iron. GEORG G. GEDDA. U. W. 1,685,602, Sept. 25. Ni or Co is added to ordinary pig iron and the mass is so heated and puddled as to produce a wrought iron of "increased" tensile strength and elastic limit without decreasing its welding and contraction capacities. Cf. *C. A.* **21,** 3342.

Refining iron or steel. A. A. FREY. Brit. 284,976, Feb. 5, 1927. The metal is first melted under basic and reducing conditions in an open-hearth or elec. furnace and the slag is removed; the molten metal is then heated under basic and oxidizing conditions either in the same furnace or in a converter and the slag removed, and the metal thus produced is treated in a converter with a reducing gas such as H. An app. and various mech. details are described.

Refining iron and steel. CHARLES W. HILL. U. S. 1,686,087, Oct. 2. Regulated and controlled vols. of gases such as O or air or H are forced into the molten metal while controlling the temp. and pressure of the molten metal so as to control the amt. of gases absorbed and the character of the metal produced. An app. is described.

Coating iron or steel with other metals. R. PALMER (to British Thomson-Houston Co., Ltd.). Brit. 284,302, Jan. 27, 1927. Before plating iron or steel with a metal such as Ni which readily alloys with and penetrates the iron on heating, the iron or steel is coated with another metal such as Cu which is less sol. in the Fe, and, after the second coating, the body is heated in an inert or reducing atm. to the alloying temp. Also, Cr or W may be coated onto an intermediate layer of Cu, and Ni onto an intermediate layer of Ag. It is also stated that Ni may be plated on Cr, W on Ni, and Cr on W, employing in each case an intermediate layer of Cu. The Cu may if desired be deposited by nonelectrolytic action such as by tumbling the iron in $CuSO_4$.

Steel. JOSEPH R. C. MARSH (to Francis N. Bard). U. S. 1,684,841, Sept. 18. A stream of molten metal is added to loose flake graphite in such a state of subdivision as to be highly mobile so that the molten metal will form an intermixed current of graphitic material and metal, rapidly and completely to carburize the metal.

Steel. ELECTRO METALLURGICAL COMPANY. Fr. 635,911, June 13, 1927. An alloy of steel contains 1 to 2% Mn, less than 1% C and Zr. The content of C is preferably less than 0.7%, and the Mn and C together not more than 2.5%. The steel obtained is 20% superior to a similar steel not contg. Zr. Cf *C. A.* **21,** 729.

Steel. GRANULAR IRON COMPANY. Fr. 635,692, June 8, 1927. Fe ore is reduced without fusion, and the Fe is put into an elec. furnace, where it is melted, any desired addns. being then made.

Titanium steel. WALTHER MATHESIUS. Can. 283,690, Oct. 2, 1928. An Fe alloy practically free from C has a content of Ti sufficient to form a steel, but below the amt. which would render the alloy unforgeable; other metals known to improve the properties of steel are also present.

Tempering steel. OTTO KRÖNING and RUDOLF BOËS. Fr. 635,695, June 9, 1927. A hard steel is obtained by a simple chilling in juice of onions or the like previously treated with acids and chlorinated. Thus, a suitable liquid is a mixt. of 94 parts onion juice, 4 parts AcOH and 2 parts $CaCl_2$.

Increasing the resistance of steel wires. VEREINIGTE STAHLWERKE A.-G. Fr. 635,487, June 3, 1927. See Brit. 272,240 (*C. A.* **22,** 1754).

Apparatus for testing the homogeneity of steel rods or other magnetizable objects. MAX E. BERLOWITZ (to Magnetic Analysis Corp.). U. S. 1,686,676, Oct. 9.

Apparatus for testing the properties of steel taps, drills or other magnetizable objects. CHARLES W. BURROWS (to Magnetic Analysis Corp.). U. S. 1,686,679, Oct. 9.

Magnetic system for testing the physical properties of quenched hardened steel articles or other magnetizable objects. ELMER J. IMES (to Magnetic Analysis Corp.). U. S. 1,686,815, Oct. 9.

Magnetic device for testing welded seams of iron or steel or other metals. THOMAS SPOONER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,685,965, Oct. 2.

Hydraulic testing and heating treatment of drums for steam boiler plants or other hollow metal articles. VEREINIGTE STAHLWERKE A.-G. Brit. 285,449, Feb. 17, 1927.

Testing apparatus for measuring and recording comparative effects of heating

articles such as those of steel for the purpose of determining suitable heat treatments. ROLAND B. ALEXANDER and WILLIAM H. ROWAN. U. S. 1,685,973, Oct. 2.

Apparatus for rustproofing iron bands by passing them through a bath of heated oil or grease. C. RÖTZEL and G. KRUG. Brit. 284,191, Jan. 22, 1927.

Preventing corrosion of copper apparatus by organic acids. SOC. CHIMIQUE DES USINES DU RHONE. Brit. 284,685, Feb. 4, 1927. Free O or materials such as Cu acetate which promote oxidation are removed from materials coming into contact with Cu by electrolysis, pptn. or use of various reducing agents. *E. g.*, dil. HOAc to be concd. in Cu app. may be passed through Fe turnings to remove Cu acetate and dissolved O.

Production of a layer of aluminum on metals. METALLBANK UND METALLURGISCHE GES. A.-G. Fr. 635,996, June 15, 1927. Diffusion layers of Al are produced on metals such as Fe or Cu by treatment with a hardening powder contg. 8–30% Al. The powder is prepd. by adding to an indifferent agent, such as clay or alumina, 8% of Al or Al alloys, and heating the mixt. in an indifferent atm. to 700–1200°, while adding more Al to the desired quantity. $(NH_4)_2CO_3$ or double salts such as NH_4 ferrous chloride may be added to the powder.

Treating tin plate scrap. L. U. LA CORSA. Brit. 284,691, Feb. 5, 1927. Tin plate scrap is leached with a soln. of a ferric salt such as $FeCl_3$ and electrolyzed for recovery of Sn. $FeCl_3$ and NH_4Cl are preferably used together for the leaching and Cl may be passed through the soln. $FeSO_4$ together with $(NH_4)_2SO_4$ also may be used for the solvent soln. Various details are given.

Cupola for alloys. EUGEN PIWOWARSKY. Fr. 635,338, May 31, 1927. The lower part of a cupola for alloys of Fe poor in C is conical with very small cross-section towards the base, and this part is filled with graphite to lessen the absorption of C

Alloy. WILLOUGHBY S. SMITH and HENRY J. GARNETT. Can. 283,647, Oct. 2, 1928. A C-free alloy suitable for loading telephone conductors comprises Ni 30–33, Fe 58–65, Cu 2–6 and Mn not exceeding 1%. It is annealed in an atm of N at 850–950° and cooled in an atm. of N. Cf. *C. A.* **22**, 2917, 3623.

Alloys of chromium. ELECTRO METALLURGICAL COMPANY. Fr. 635,581, June 7, 1927. See Can. 282,700 (*C. A.* **22**, 4102).

Metals or metal alloys low in carbon produced directly from ore. HENNING G. FLODIN and EMIL G. T. GUSTAFSSON. U. S. 1,686,206, Oct 2 Finely divided ore such as Fe ore is intimately mixed with finely divided carbonaceous material such as coal, coke or charcoal proportioned in quantity for the reduction of the ore and for the desired content of C in the product; this mixt. is formed into briquets together with water glass, molasses or other suitable binding agent and the briquets are fed in repeated quantities into an elec. furnace to effect an even reduction and regular operation in the course of which the material is reduced and melting is effected on top of a slag bath U. S. 1,686,207 specifies an endothermic direct reduction process for producing C binding metals and alloys such as iron or its alloys consisting in charging an elec furnace, having an electrode which can be raised and lowered and in which heat is thus developed by elec. resistance in the slag bath, with a solidified mixt contg finely divided oxide ore such as Fe and Cr ores and finely divided reducing agent in the desired proportion for reduction and carbonization, reducing and melting on a slag bath and controlling the temp. of the slag bath and of the metal by heating the upper layer of the slag bath and regulating the position of the electrode and passing an arc between the electrode and slag bath.

Alloys of high magnetic permeability. W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 284,789, Nov. 6, 1926. Alloys which may be heat-treated in various shapes to develop high magnetic permeability and which are suitable for loading signalling conductors contain Fe together with Ni 32–42, Si or Al 1–4%, and 1–4% of a material for increasing the elec. resistance such as Cr, W, Mo or V. Fe is preferably 55–65% and the alloys are free from or low in C, but may contain a small proportion of Mn or other deoxidizing metal. Cf. *C. A.* **22**, 2138, 3623.

Alloy for use in magnetic circuits of multiplier devices for high-frequency currents or other electrical devices. MARIUS LATOUR (to Latour Corp). U. S. 1,687, 298, Oct. 9. An alloy is used comprising Fe together with Ni 33.9 and Mn 1.15%.

Melting aluminum and aluminum alloys. A. I. GOLDMAN. Russ. 4343, Jan. 31, 1928. A flux composed of a mixt. of NaCl and more than 10% of $CaCl_2$ is used.

Aluminum alloys. A. GEYER. Brit. 284,722, Feb. 4, 1927. In producing Al alloys which may contain Cu, Mn, Si, Mg, Fe, C, W, Ni, Mo, Cr and Cd, oxidation of the molten bath is prevented by covering it with a layer of broken coal and by introducing powd. coal (which may be wetted) into the bath. Carbides, metal salts and reducing gases also may be used.

Aluminum alloys. Aluminum Company of America. Fr. 635,766, June 10, 1927. Al alloys which are liable to corrode are covered with an adhering layer of Al or non-corroding Al alloy by casting the melted Al alloy in contact with one or several plates of non-corroding metal and pressing and heating the combination thus formed.

Bronze alloy. Soc. metallurgica Giacomo Corradini. Fr. 635,540, June 4, 1927. A bronze alloy which can be worked hot or cold contains 50 to 60% Cu, 40 to 30% Zn, 0.25 to 1.5% Pb, 0.25 to 1.5% Fe, 2 to 6% Mn and 2 to 6% Ni.

Copper-tin-lead alloy. George H. Bender. U. S. 1,685,975, Oct. 2. An alloy which is suitable for bearings is formed of Cu 70.3, Sn 24.53 and Pb 5.2 parts.

Iron-chromium-silicon alloy. Percy A. E. Armstrong (to Ludlum Steel Co.). U. S. 1,686,223, Oct. 2. In making wrought articles contg. Fe with Cr about 13% or more, Si about 0.3-5% and C under 0.05%, degasified molten Fe is combined with preheated chrome alloy material, cast into ingots, worked to reduced size, heated to an initial rolling temp. of about 1140-1260° and the metal is finish rolled with substantially max. draft roll passes, the rolling being finished at a temp. about 600° or higher, to produce an article with a stable surface.

Magnesium alloy. Wm. R. Veazey (to Dow Chemical Co.). U. S. 1,685,653, Sept. 25. A Mg alloy contains Cr 0.1–1.0% which serves to give strength and toughness. Cf. *C. A.* **22,** 1569.

Bending magnesium alloys. I. G. Farbenind. A.-G. Brit. 284,313, Jan. 28, 1927. Section rods or sheets of Mg alloy are heated to 100-400° and bent by passing them through profiled rollers made of Mg alloy which may be hardened superficially as by hammering. Alternatively, ordinary rolls may be covered with rings of Mg alloy.

Drawing magnesium alloy section-bars. I. G. Farbenind. A.-G. Brit. 284,317, Jan. 28, 1927. A sheet of Mg alloy is drawn through skelping dies at a temp. of 100–400°. Various mech. features are described.

Extruding bars from magnesium alloys. I. G. Farbenind. A.-G. Brit. 285,029, Feb. 9, 1927. Mech. features.

Nickel alloys of high resistance. W. S. Smith, H. J. Garnett and J. A. Holden. Brit. 285,565, Nov. 17, 1926. Alloys are formed contg. Ni 70–80, Cr 15-25 and Co 2-7% and which may also contain up to about 10% of Fe which may replace some of the Cr and Ni. For making wire, tape or ribbons the alloy is made substantially C-free but for castings, rods or forgings 0.1–0.2% C may be present. Traces of a deoxidizer such as Mg or Cd also are preferably added.

Nickel-beryllium alloys. Georg Masing and Otto Dahl (to Siemens & Halske A.-G.). U. S. 1,685,570, Sept. 25. Alloys of Ni contg. up to 5% Be are improved by heating to above 700°, after cooling and afterwards mech working.

Steel alloys. F. Krupp A.-G. Brit. 284,314, Jan. 28, 1927. Steel alloys are formed contg. Cr 8–18, Mn 2-12, W 3-12, C up to 1% (*e. g.*, Cr 12-14, Mn about 5, W 5 and C 0.5% are suitable).

Alloy containing zirconium and copper. Alexander L. Feild (to Electro Metallurgical Co.). U. S. 1,684,696, Sept. 18. An alloy of Al and Zr is introduced into a superheated bath of Cu to form alloys which, *e. g.*, may be composed of Cu 63.47, Zr 10.59, Al 4.67, Si 4.43 and C 0.07 parts.

Zinc-lead dust. Minton H. Newell (to Alloys Co.). U. S. 1,687,034, Oct. 9. Zn is vaporized, Pb oxide is decompd. in the Zn vapor and the mixt. is then cooled with sufficient rapidity to condense the Zn in finely divided condition. An app. is described. The product obtained by this method is suitable for pptg. metals from cyanide solns.

Forming seamless turbine tubes, free from incipient cracks, from metal plates. Julius Grossweischede and Georg Reichenbecher (to Vereinigte Stahlwerke A.-G.). U. S. 1,685,402, Sept. 25. Mech. features.

Thermal cut-out for electric circuits. Maurits J. Sandin (to Westinghouse Elec. & Mfg. Co.). U. S. 1,685,958, Oct. 2. Structural features.

Heat treatment of permanent magnets. James E. Gee and Frederick S. Gee. U. S. 1,685,877, Oct 2. Before magnetizing, castings are softened by heating and then hardened by first heating to approx. 1200°, then cooling and leaving for about 18 hrs., reheating to approx. 750°, allowing to cool, and finally heating to about 1000° for 10 min., allowing to cool, and leaving for about 12 hrs. before magnetizing.

Corrugated container for annealing metals, etc. J. B. Green. U. S. 1,684,391. Sept. 18. Structural features.

Annealing stove for metallic wires. Akt. Ges. Brown, Boveri & Cie. Fr. 635,948, June 14, 1927. Metal disks which are good conductors of heat are placed between the layers of wire. When a crucible is used, its walls and sides are made of good conductors.

Galvanizing. FELIX KIRSCHNER and JOSEF HESS. Fr. 635,308, May 23, 1927. An app. is described for galvanizing articles in bulk.

Galvanizing apparatus. FELIX KIRSCHNER and JOSEF HESS. Austrian 109,151, Nov. 15, 1927. Constructional improvements are described in app. of the type comprizing a galvanizing vessel rotating around an inclined axis.

Electric welding. ALLGEMEINE ELEKTRICITÄTS-GES. Brit. 285,513, Feb. 18, 1927. In effecting resistance welding a higher voltage is used for the preliminary heating than for the actual welding. Numerous details of elec. app. are specified.

Welding high-carbon steel. JOHN H. DEPPELER (to Metal & Thermit Corp.). U. S. 1,686,603, Oct. 9. A thin body of low-C iron is interposed between surfaces which are then butt welded by contact with molten aluminothermic metal.

Electric arc welding apparatus. J. B. GREEN (to Chicago Steel & Wire Co.). U. S. 1,685,082, Sept. 25.

Electrodes for arc welding. B. TURNER and FERRO-ARC WELDING CO., LTD. Brit. 285,128, Nov. 9, 1926. A twin electrode for use with a. c. consists of 2 rods or wires bound together with asbestos yarn and which may carry fluxes such as lime, china clay, Na silicate or Na_2CO_3. Brit. 285,129 also specifies generally similar electrodes.

Electrodes for arc welding with alternating current. K. V. PETRAN. Russ. 4361, Jan. 31, 1928. Iron wire is heated rapidly to a high temp. (*e. g.*, 950°), cooled, the scale removed by HCl, the acid washed off with H_2O and the electrodes are kept in a soln. of soda (*e. g.*, 5%) until they are coated with special flux.

Welded steam-generator drums or other vessels subjected to pressure. C. WALLMANN and F. NEHL. Brit. 285,450, Feb. 17, 1927. Receptacles, conduits, etc., are made from ingot steel contg. up to about 0.3% Mo and may be hydraulically tested, heated to just above a max. crit. point and then cooled.

Separating metals welded or similarly attached together. EISEN- UND STAHLWERK W. PEYINGHAUS. Brit. 285,508, Feb. 18, 1927. Metals such as those formed in part of iron or steel and in part of attached brass or gunmetal are heated in a reducing or inert atm. to a temp. below the m. p. of the metals but at which the brass or like metal becomes brittle so that it may be broken away from the iron or steel by light hammer blows.

Solder. METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 285,485, Feb. 18, 1927. A hard solder suitable for use with gray pig iron, cast steel and like metals comprises Cu 42–60, Ni 1–10, Si up to 3%, and the remainder Zn.

Aluminothermic soldering. FÉLIX LANGE. Fr. 635,389, June 1, 1927. The cavity of the soldering mold has two compartments in communication, one of which is filled with an aluminothermic mixt. which reacts, while a previously melted charge is poured into the second contg. the joint to be soldered.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Hypothesis of valency-deflection. CHRISTOPHER K. INGOLD AND JOCELYN F. THORPE. *J. Chem. Soc.* **1928**, 1318–21.—Polemical with Hückel (*C. A.* **22**, 1141). C. J. WEST

Crystals of a new organic compound. J. J. P. VALETON. *Z. Krist.* **66**, 516(1928).—Crystals of *3-methyl-5-methylaminohydantoylmethylamide*, NH.CO.NMe.CO.C(NHMe)-CONHMe, are clear and colorless, with m. p. 187°. They are triclinic, with $a:b:c$ = 1.2493:1:1.0012, and $\alpha = 90°38'$, $\beta = 93°52'$ and $\gamma = 107°39'$. L. S. RAMSDELL

Rapid methods of obtaining pure methane and ethane. W. M. KEMULA. Jan. Kazimir Univ. *Przemysl Chem.* **12**, 411–2(1928).—CH_4 prepd. by L. Moser's method (*Die Reindarstellung von Gasen.* **1920**, 128; *C. A.* **15**, 1651) is passed through a glass tube 80 cm. long and 2 cm. diam., which is packed with CuO for $^3/_4$ of its length and with reduced Cu screen through the remainder of the tube. This is heated to 360° in an elec. furnace. Gas flowing at 2 l. per hr. is passed through 1:3 KOH soln. C_2H_6 prepd. also according to Moser's method (*l. c.* page 133) is similarly treated, except that it is heated only to 280°. Gases so treated are practically 100% pure. A. C. ZACHLIN

The action of the alkyl chlorides in the Würtz reaction. HARRY F. LEWIS. *Proc. Iowa Acad. Sci.* **34**, 222(1927).—At the last meeting of the Iowa Acad. a report was made on the mechanism of the Würtz reaction with Bu and iso-Bu bromides. The

prepn. of octane in this manner is costly and an attempt has been made to replace the bromide by the chloride. Either in the presence or absence of ether as a solvent, the reaction is difficult to control. Yields of octane up to 20% based on the Bu chloride have been obtained. An extremely inflammable by-product is produced and it is difficult to complete a prepn. without at least one fire. With octane itself as a solvent, several bad explosions resulted. W. G. GAESSLER

Physico-chemical and thermodynamic investigations on hydrocarbons. M. AUBERT AND J. VILLEY. *Chimie et industrie* Special No., 258–61(April, 1928); cf. *C. A.* **21**, 645.—The investigation previously outlined, which is of very wide scope, has been started, and the results obtained to date by a no. of co-workers are briefly discussed (cf. following abstracts). A. PAPINEAU-COUTURE

Analysis of mixtures of hydrocarbons by means of their refractive dispersion. R. MOUTTE. *Chimie et industrie* Special No., 262–3(April, 1928); cf. Dixmier, *C. A.* **21**, 645.—Using the Pulfrich refractometer and the Féry disperso-refractometer (Chéneveau and Vaurabourg, *C. A.* **22**, 3553) M. obtained the following values for $\Delta n/d \times 10^4$ (n for $\lambda_1 = 0.589\mu$ and for $\lambda_2 = 0.436\mu$): octane 118, nonane 116.6, decane 115.6, undecane 117, duodecane 119, tetradecane 114.6, octene 145.7, nonene 133.9, decene 136, duodecene 132.9, tetradecene 129.8, hexadecene 126, undecadiene 150, cyclohexene 141, 4-methylcyclohexene 142, 3-methylcyclohexene 142, 2-methylcyclohexene 148, PhEt 224, styrolene 340. With an Abbé refractometer, for $\lambda_1 = 0.486\mu$ and $\lambda_2 = 0.656\mu$, the following values were obtained: hexane 104.4, heptane 101.4, decane (di-isoamyl) 101.9, cyclohexane 99, C_6H_6 189.7, PhMe 186.3, comm. xylene 179.4, cyclohexene 114.5. Though the values for different hydrocarbons of a given series show some variation, in using them for the analysis of mixts. of hydrocarbons of different series, the values selected should preferably be those of the hydrocarbon having approx. the same b. p. as the fraction being analyzed. This method for the detn. of aromatic hydrocarbons in aviation gasoline free from C_2H_4 hydrocarbons always gave results agreeing closely with those obtained from detn. of the critical soln. temp. in $PhNH_2$. A. PAPINEAU-COUTURE

Identification of hydrocarbons by means of their magnetic rotatory power. A. JAVELLE. *Chimie et industrie* Special No., 264–6(April, 1928); cf. Jacob, *C. A.* **21**, 645.—Using the method and app. previously described by Jacob, which Javelle studied and to which he made certain refinements, and taking Verdet's figures of $k = 1.53 \times 10^{-2}$ for H_2O at 20.2° and $k_1 = 3.38 \times 10^{-2}$ for C_6H_6 at 20.8°, J. obtained the following values for k at $\lambda = 0.546\ \mu$: hexane (18.3°) 1.46, heptane (21.4°) 1.51, octane (20.6°) 1.52, C_6H_6 (20.8°) 3.38, PhMe (20.3°) 3.08, PhEt (20.8°) 3.03, cyclohexane (20.1°) 1.47, dimethylcyclohexane (18.3°) 1.58, cyclohexene (20.6°) 1.747, 2-methylcyclohexene (18.25°) 1.71, 4-methylcyclohexene (18.5°) 1.75, 3-methylcyclohexene (18.4°) 1.753. A study of the variation of the value of k for mixts. of cyclohexane and PhMe, cyclohexane and C_6H_6, and cyclohexene and PhMe showed that k is a linear function of the compn., in accordance with Biot's law of additivity. The possible error in the detns. carried out on these mixts. was less than 0.25%. A. P.-C.

Investigation of the specific inductive power of hydrocarbons. R. TOUSSAINT. *Chimie et industrie* Special No., 270–4(April, 1928).—With a view to the possible application of the detn. of sp. inductive power to the identification and analysis of hydrocarbons, a method has been devised based on the electrometric detn. of the capacity of a given condenser with air as a dielec. and then with the liquid under investigation as dielec. The requirements of such a method and of the app. used in carrying it out are discussed, and the app. adopted is described. The limit of accuracy obtainable is of the order of 0.005. The following values (at 23°) were obtained: C_6H_6 2.275, heptane 1.978, hexane 1.884, cyclohexane 2.026. A study of the variation of the sp. inductive power of mixts. of hydrocarbons as a function of their compn., which was carried out on hexane-C_6H_6 and pentane-C_6H_6 mixts., showed that this variation is not a linear function. A. PAPINEAU-COUTURE

The hydrogenation of organic compounds. E. J. LUSH. *Notiz. chim.-ind.* **3**, 489–95(1928).—A review, with 22 references. C. C. DAVIS

The succinic derivative of triaminophenol. MARIO COVELLO. *Atti II congresso naz. chim. pura applicata* **1926**, 1343.—2,4,6-$(H_2N)_3C_6H_2OH$ fused with $\underbrace{CH_2.CO.O.CO.CH_2}$ (3 mols.) at 200° gives quant. the *trisuccinic deriv. of 2,4,6-triaminophenol*, 2,4,6-$(\underbrace{CO.CH_2.CH_2.CO.N}){}_3C_6H_2OH$, easily oxidized by HNO_3 (d. 1.43) to *2,6-bis(succinylamino) quinone*. Reduced with SO_2 this gives the *hydroquinone*, pale yellow. C. C. DAVIS

Thermal decomposition of gaseous hydrocarbons. S. MANTEL. Chem. Research Institute, Warsaw. *Przemysl Chem.* **12**, 333-42(1928).—Preheated natural gas, 97%, was passed through a furnace and the products were measured at the end of reactions under various conditions. Slower rate and larger catalyst surface cause greater percentage decompn. H_2 with 0.7% CH_4 impurity was obtained. No higher purity was attained up to 1700°. Periodical and patent literature on the subject is reviewed and a bibliography is given. A. C. ZACHLIN

The action of the silent electrical discharge on the hydrocarbons of the ethylene series. D. N. PRYANISHNIKOV. Landwirtschaftl. Timirjasevschen Akad., Moskau. *Ber.* **61B**, 1358-63(1928); cf. Demjanov and P., *C. A.* **21**, 3344.—In this paper, which is a continuation of the work on the action of the silent elec. discharge on C_2H_4, MeCH:CH_2, $Me_2C\cdot CH_2$ (I) and $(MeCH\cdot)_2$, are reported the results of a more thorough study of the liquid polymerization product obtained from I. It shows d_4^{20} 0.831, n_D^{20} 1.4483, av. mol. wt. 202, C 85.46%, H 14.60%, I no. (Wijs) 156; 30% b_{740} up to 150°. The light fractions contain more H than corresponds to the formula C_nH_{2n}, *i. e.*, the polymerization is accompanied by a distribution of the H. The satd. hydrocarbons resulting from this distribution, which are more stable and have a lesser tendency to further transformations, are found in the lighter fractions, while the unsatd. compds., which polymerize more rapidly, serve for the production of non-volatile, resinous products of high mol. wt. The polymerization is also accompanied by the splitting off and addn. of hydrocarbon radicals, which explains the formation of fractions b 32-52° and 75-85° and having mol. wts. corresponding to compds. of the C_6 and C_7 series. The compn. of these fractions indicates that they contain 20-30% of C_nH_{2n} and 70-80% of C_nH_{2n+2} compds. and the addn. of Br and decolorization of $KMnO_4$ points to the presence of compds. with double bonds. Polymethylenes, which have a much higher b. p., can be present in only very small quantities. The 32-52° fraction most probably contains $(Me_2CH)_2$ and $(Me_2C\cdot)_2$, the 75-85° fraction $CH_2(CHMe_2)_2$, $PrCMe_3$, Me_2CHCMe_3 and the corresponding pentenes. The higher fractions are considerably richer in unsatd. hydrocarbons and also contain naphthenes. After treatment with CrO_3-H_2SO_4 their compn. corresponds to 60% C_nH_{2n} and 40% C_nH_{2n+2}. The presence of naphthenes is also indicated by the lack of additive power. Since oxidation with CrO_3-H_2SO_4 gives AcOH and a little HCO_2H (as well as acids with a higher mol. wt.) it is probable that among the compds. with double bonds in the original fractions (before treatment with CrO_3-H_2SO_4) are present the ordinary polymerization products of I contg. the Me_2C: grouping. No attempts were made to prove the presence of aromatic compds., but the consts. of the products indicate that no appreciable quantities are present. The character of the products depends greatly on the conditions, especially on the length of the expt., every prolongation increases the yield of highly polymerized, non-volatile products. Increase in the voltage, on the other hand, seems not to influence the character of the products to the same degree but essentially only to accelerate the polymerization; the yield increased several-fold on raising the voltage from 12,000 to 20,000-25,000. The structure of the original hydrocarbon has a great influence on the velocity of the reaction; cyclopropane is apparently polymerized only half as rapidly as $MeCH\cdot CH_2$ under the same conditions. The elec. energy consumed could not be detd. for lack of a wattmeter, but is probably not very great. The resinous products formed can be converted into volatile hydrocarbons by the cracking process. C. A. R.

A new class of compounds with tervalent carbon. STEFAN GOLDSCHMIDT WITH ALFRED SADLER, ERICH GELBER, HERBERT SCHÜSSLER AND ADOLF VOGT. *Ber.* **61B**, 829-38(1928).—The analogy between C_2H_6 and N_2H_4 finds expression, beyond merely formal lines, especially in the aromatic substitution products of the 2 substances. The dissocn. of $(CPh_3)_2$ into CPh_3 corresponds to that of $(NPh_2)_2$ into Ph_2N. Analogous to Ph_2NNPh is the monomol. Ph_3CCPh_2. Qual., the 2 series differ in the generally lesser dissocn. of the N as compared with the corresponding C derivs. The $\alpha,\alpha,\alpha',\alpha'$-tetraphenyl-$\beta,\beta'$-diacyltetrazanes (*C. A.* **16**, 2852) are characterized by their extensive dissocn. into the corresponding hydrazyls and it therefore seemed that it should be possible to synthesize the analogous C radicals, Ph_3CCBz_2, from the corresponding ethanes (as yet unknown). All attempts to prep. the latter by treating, *e. g.* Bz_3CMe with $BrCHPh_2$, Ph_3CMe with $BrCHBz_2$ or Ph_3CCl with $MeCHBz_2$, failed, however. Better results were obtained by condensing Ph_3CCl and CH_2Bz_2 with $NaNH_2$; this yielded a small quantity of a compd. which after much purification proved to be a hydrocarbon (I) of the expected compn. The chief products of the reaction, however, were Ph_3CNH_2 and $(Ph_3C)_2O_2$, together with a large quantity of uninviting tars. With K as the condensing agent, the I was finally obtained in about 30% yield by carrying

out the reaction in very concd. C_6H_6 soln. and scrupulously excluding moisture and O; along with the I were formed much tar and more or less considerable quantities of Ph_3CH. During the reaction there develops a deep red color which, however, finally disappears again. The compn. and mol. wt. of the I correspond to the formula Ph_3CCHBz_2 but on vigorous treatment with Br it gives a *di-Br deriv.*, $C_{34}H_{24}O_2Br_2$ (II), which holds both Br atoms very loosely; boiling MeOH splits them off (with differing velocity) as HBr through an intermediate *bromocarbinol*, $C_{34}H_{24}O_2Br(OH)$ (III), which was isolated. Again, on boiling several hrs. in AcOH with CrO_3, I yields, not Ph_3COH + BzOH, but p-$BzC_6H_4CO_2H$ + BzOH. I can therefore be only *ω,ω-diphenyl-ω′,ω′-dibenzoyl-p-xylene*; possibly Ph_3CCHBz_2 is first formed and rearranges into I by migration of the $CHBz_2$ group. Oxidation of II likewise yields only BzOH and $BzC_6H_4CO_2H$ and no brominated product; this and the ease with which it is hydrolyzed (by boiling MeOH, as stated above, and also by concd. H_2SO_4, in which it dissolves with deep brown-red color) indicate that both Br atoms are in tertiary aliphatic combination, $Ph_2CBrC_6H_4CBrBz_2$. Since $Ph_2CBrC_6H_4CBrPh_2$ with metals gives the quinomethane $Ph_2C{:}C_6H_4{:}CPh_2$, II might have been expected to react in the same way but as a matter of fact it does not. With Cu or Ag, it loses only one Br atom with formation of deep brown-red solns. of a *methyl* (IV), which could not be obtained in cryst form. In soln. it is entirely free of the dimer, as shown by mol. wt. detns. and by application of Beers' law; towards O it is exceedingly unreactive, undergoing no appreciable alteration after several days; it does not react with other radicals (NO, Ph_3C, Ph_2N, diphenyltrinitrophenylhydrazyl); it is sensitive only towards NO_2 (with which it forms no cryst. products, however), halogens and the halogen acids; with Br, *e. g.*, it regenerates II, taking up 1 atom Br. Among the metals, Zn occupies an exceptional position in its reaction with II; in the form of Zn dust it gives, not a quinomethane ether, but halogen-free products (probably formed through IV), *viz.* $Ph_2CHC_6H_4CHBz_2$, and a compd. (V), contg. 2 atoms more of O and characterized by its slight soly.; V is very probably a *peroxide carbinol*, $(HOC_{34}H_{24})_2O_2$. Of the 2 possible structures, $Ph_2CC_6H_4CBrBz_2$ and $Ph_2CBrCBz_2$, for IV, the 2nd is probably the correct one, for the 1st represents a deriv. of Ph_3C and such a substance would be expected to have the properties of a Ph_3C compd., especially the sensitivity to O, while the 2nd formula represents a ketomethyl (hitherto known only in cyclic compds. as the tautomers of aroxyls, in which the sensitivity to O can be greatly diminished). I, m. 165–6°, sol. in concd. H_2SO_4 almost without color, mol. wt in freezing C_6H_6 431; its boiling alc. soln. is colored a characteristic deep yellow by NaOH. *ω,ω-Diphenyl-ω′,ω′-dibenzoyl-p-xylene dibromide* (II), m. 171–3°, mol. wt in C_6H_6 622. V, m. 195–6°. III, m. 181°, dissolves in concd. H_2SO_4 with deep yellow-red color, is unchanged by long boiling in C_6H_6 with metals (Cu, Ag powder, Zn dust). The red solns. of IV are decolorized by NO_2 and the color is not restored by heating. C. A. R.

Nitrogen trichloride and unsaturated hydrocarbons. II. GEORGE H. COLEMAN, G. M. MULLINS AND ELIZABETH PICKERING. State Univ. of Iowa. *J. Am. Chem. Soc.* **50,** 2739–41(1928); cf. *C. A.* **18,** 1812.—The reaction products of NCl_3 with $CH_2{:}CH_2$ are N, NH_4Cl, CH_2ClCH_2Cl and $CH_2ClCH_2NCl_2$, converted by HCl to $CH_2ClCH_2NH_2$ (13.7% yield); Bz deriv., m. 104–5°. $CH_2{:}CH_2$ requires about 2 weeks at 20–5° for the completion of the reaction. $MeCH{:}CH_2$ reacts similarly but more rapidly than $CH_2{:}CH_2$; of the 2 possible addn. products, only $MeCH(NCl_2)CH_2Cl$ was definitely shown to be formed; the yield of amine is 19.5%; the Bz deriv., m. 74–5°. $Me_2C{:}CH_2$ reacts in 2–3 hrs., even at −45° to −50°; in this reaction most of the $Me_2C(NH_2)CH_2Cl$ ppts. as the HCl salt along with the NH_4Cl; yield, 12.2%, Bz deriv., m. 83–4°. 2-Pentene and cyclohexene behave similarly; the yields of amine-HCl were 10–21 and 23%, resp.; the Bz derivs., m. 106–7° and 162–3°, resp. **III. Nitrogen trichloride and diphenyl ketene.** G. H. COLEMAN AND ARTHUR W. CAMPBELL. *Ibid* 2754–7.—$PhCH{:}CH_2$ (200 mols. in 400 g. CCl_4) and 71 mols. NCl_3 in 250 g. CCl_4 give 46.4 mg. atoms N, 3.2 mg. mols. NH_4Cl and 19.6 mg. mols. (27.6%) of the amine, $PhCH(NH_2)CH_2Cl$, whose Bz deriv. m. 133–4°. $PhCH{:}CHPh$ and NCl_3 give 70.5 mg. atoms N, 2.8 mg. mols. NH_4Cl and 16.8 mg. mols. of $PhCH(NH_2)CHPhCl$, whose Bz deriv. m. 192–3°. $Ph_2C{:}CH_2$, $Ph_2C.CHMe$, $Ph_2C{:}CHPh$ and $Ph_2C{:}CPh_2$ gave no amines under the exptl. conditions used. $Ph_2C{:}CO$ and NCl_3 give an addn. product, which, warmed with NaOH, gives $Ph_2C{:}NH$ (35%). C. J. WEST

Equilibrium in the reaction $C_2H_6 \rightleftharpoons C_2H_4 + H_2$. ROBERT N. PEASE AND ELFORD S. DURGAN. Princeton Univ. *J. Am. Chem. Soc.* **50,** 2715–8(1928).—The position of equil. in the reaction $C_2H_6 \rightleftharpoons C_2H_4 + H_2$ has been measured at 600°, 650° and 700°, equil. being approached from both sides. Some uncertainty exists because of the simultaneous formation of CH_4, but the indications are that the equil.

consts. at the 3 temps. are 0.0310, 0.082 and 0.20, resp., partial pressures being expressed in atms. The data are satisfactorily reproduced by the equation $\Delta F = -RT \ln K = 31{,}244 - 28.88\ T$. C. J. WEST

Catalytic hydrogenation of different types of unsaturated compounds. III. Hydrogenation of conjugated systems. SERGUEY V. LEBEDEV AND ANASTASIA O. YAKUBCHIK. Military Medical Acad., Leningrad. *J. Chem. Soc.* **1928**, 2190–204; cf. *C. A.* **22**, 2362.—Continuing the earlier work, the reduction of diisopropenyl, divinyl and piperylene has been studied. The hydrogenation of H_2C:CMeCMe:CH_2 proceeds at a similar rate to that of isoprene, 68–70% of the H necessary for satn. being absorbed at a uniform velocity; in the next stage the rate of absorption increases (22.5% H absorbed) and then falls abruptly in the 3rd and last section (8.5% H). The 2nd section corresponds to H_2C:CMeCHMe_2, the 3rd to Me_2C·CMe_2. The compn. of the reaction mixt. after 25, 50 and 69% hydrogenation is given and also the behavior of mixts. with standard ethylenic derivs. of different degrees of substitution. The original should be consulted for the details. All 3 compds. belong to the so-called Type II of conjugated systems. C. J. WEST

Relative rates of reaction of olefins in combustion with oxygen and in oxidation with aqueous potassium permanganate. H. S. DAVIS. *Ind. Eng. Chem.* **20**, 1055–7 (1928).—Known mixts. of C_2H_4 and propene and of C_2H_4 and isobutene were exploded with O and also oxidized in H_2O with $KMnO_4$. In every case it was found that propene or isobutene was oxidized faster than the C_2H_4. The reaction with Br was similar. In bromination of the olefins the main reaction is Br addn. to the unsatd. C atoms. In combustion there is good evidence that the primary reactions are the addn. of 1 or 2 atoms of O to the olefin. The rates of combustion and of bromination of olefins can both be increased by intensive drying. D. F. BROWN

Relative rates of bromination of the olefins. HAROLD S. DAVIS. Mass. Inst. Tech. *J. Am. Chem. Soc.* **50**, 2769–80(1928).—C_2H_4 brominates in CCl_4 at a rate measurable with time; if the solns. are dried and kept away from bright light, the reaction requires hrs. and even days for completion. The rate of the dark reaction of C_2H_4 with Br in CCl_4 varies greatly with the quantity of moisture in the soln.; the rate is increased over 5 times on the addn. of 5% by vol. of CCl_4 satd. with H_2O; O and HBr have no influence on the rate. Bright light enormously increases the rate of bromination of C_2H_4 in CCl_4 (shown by figure). The rate of the dark bromination increases progressively as the temp. is lowered from 25° to 0°, the ratio of K (25°/0°) varying from 1 20 to 1:130. It is suggested that the dark bromination of C_2H_4 in CCl_4 proceeds mainly through a Br hydrate and that the concn. of this hydrate increases as the temp. is lowered from 25° to 0°. The bromination of C_3H_6 is considerably faster at 0° than at 25°; however, temp. has little effect on the rate of bromination of Me_2-C:CHMe or diisobutene. Light increases the rates of bromination of the olefins but decreases the relative difference between them. The methods used for following the course of the bromination were color comparison with a standard Br soln. and titration of the Br. Care must be taken in the preservation of the dried Br-CCl_4 solns.
C. J. WEST

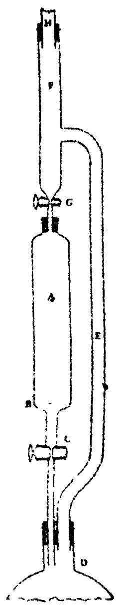
Relative rates of absorption of the gaseous butenes into sulfuric acid. HAROLD S. DAVIS. Mass. Inst. Tech. *J. Am. Chem. Soc.* **50**, 2780–2(1928).—Calcns. on the relative absorption of the 3 butenes into H_2SO_4 have been made from the exptl. data of Michael and Brunel (*C. A.* **3**, 1165). With 1-butene as 1,2-butene is 2 and isobutene is 280–390. C. J. WEST

Reaction between acetylene and sulfur at temperatures up to 650°. JOHN B. PEEL AND PERCY L. ROBINSON. Armstrong College, Newcastle-on-Tyne. *J. Chem. Soc.* **1928**, 2068–70; cf. Briscoe and Peel, *C. A.* **22**, 3657.—In the reaction between S and C_2H_2, the liquid condensed at lab. temp. contains CS_2(I), thiophene(II) and thiophthene (III). At about 325°, 38% of the S was converted into a brown oil, contg. 77% I, 9% II and 6% III; at 500°, 74% of the S was converted into a brown oil, contg. 77% I, 12% II and 6% III; at 650°, 77% of the S was converted into a product contg. 83% I, 5% II and 3% III. The remaining S probably converts the C_2H_2 into C and H_2S. II has d_4^{20} 1.0615, γ_{20} 32.58; these data give a mol. parachor of 189.0 and the parachor of S as 46.5. C. J. WEST

Method of separation of zinc formaldehydesulfoxylate and zinc formaldehyde bisulfite. CH. SUNDER AND A. KEMPF. *Bull. soc. ind. Mulhouse* **94**, 473–4(1928).—Sealed Note 2223 of Feb. 20, 1913.—Heating Zn formaldehydebisulfite with Zn powder gives an insol. basic salt of Zn formaldehydesulfoxylate. The same basic salt can be obtained by the action of ZnO on Zn formaldehydesulfoxylate, but not on Zn formaldehydebisulfite. This allows of practically quant. sepn. of the two by treating a soln.

contg. them both with ZnO at 45–50° for 1 hr. Report. R. FLATT. *Ibid* 474–6.—The results of S. and K. were confirmed, but the sepn. was not quant., probably because the ZnO used by F. may not have been as active as the one used by S. and K., and longer time should have been allowed for the reaction. A. PAPINEAU-COUTURE

A modification of Adam's method of preparing alkyl iodides. H. S. KING. Dalhousie Univ., Halifax, N. S. *Proc. Trans. Nova Scotian Inst. Sci.* **16,** 87–91 (1928).—The app. proposed by Adams and Voorhees (*C. A.* **13,** 2032) has been simplified as shown by the fig. *A* is a cylindrical separatory funnel capable of holding 2 kg. of loose I crystals; *B* is a perforated Pt plate, to prevent clogging of the stopcock; *C* is 5 mm. in bore, *G* 3 mm. in bore; *E* 25 mm. in diam.; *F* 40 mm. in diam.; *H* is a condenser. The lower tube of *G* is flush with the stopper so that the condensate will run along the sides of *A*. A. L. HENNE



Synthetic methanol. F. VALETTE. *Chimie & industrie* **Special No.,** 235–8 (April, 1928).—A theoretical discussion of the possibilities of the synthesis of MeOH from CO and H_2, from which V. concludes that the experience gained in the synthesis of NH_3 would enable the production of MeOH independently of the manuf. of synthetic NH_3 to be readily established, that the cost would be approx. 1.18 francs per l., that the cost of MeOH equiv. to 1 l. of gasoline would be about 1.77 francs, and that it would be feasible to produce enough MeOH to replace the whole of the gasoline now being imported into France. A. P.-C.

A study of the synthesis of methanol. ÉTIENNE AUDIBERT AND ANDRÉ RAINEAU. *Ind. Eng. Chem.* **20,** 1105–10 (1928).—The effect of a large no. of metals and metallic oxides in catalyzing the synthesis of MeOH from CO and H_2 under high pressure has been studied. Reduced Cu and ZnO were the most effective. The method of prepn. of the catalyst is very important, and it is essential that the reduction be carried out at a low temp. Mixed catalysts were superior to single-component catalysts. T. S. CARSWELL

Comparative study of values obtained in synthesis of methanol. A. C. FIELDNER AND R. L. BROWN. *Ind. Eng. Chem.* **20,** 1110–2 (1928).—Values for the equil. const. in the Nernst equation have been calcd. for the reaction: $CO + H_2 = MeOH + Q$ calories, with the experimental data which have been reported by different independent observers. In spite of probable variation in the exact conditions of the expts from different labs., there is a close agreement in the values of the const. T. S. C.

Condensation of phenylenediamines with acetanilide. Salts of tolylphenylethenylamidines. H. BECKER. *Roczniki Chem.* **8,** 242–9 (1928); cf. *C. A.* **20,** 1799.—*Diphenylethenylamidine* (I) was prepd. in 98% yield by the condensation of acetanilide (II) with aniline in the presence of $POCl_3$, m. 132.5°. I.*HCl*, m. 218° (decompn.). I.*HBr*, m. 200° (decompn.). *m-Phenylenebis(phenylethenylamidine)*, *1,3-C_6H_4(N:C-(CH_3).NH.C_6H_5)$_2$* (III), m. 212.5–3°, was obtained by heating 4 hrs. on the water bath 5.4 g. II with 4.2 g. $C_6H_4(NH_2)_2.H_2SO_4$ in 50 cc. benzene with 4 cc. $POCl_3$. Yield 60%. Easily sol. in hot MeOH, EtOH and acetone, it crystallizes on diln. Moderately sol. in $CHCl_3$, slightly in benzene, CCl_4 and ether. III.*2HCl*, m. 275° (decompn.), is prepd. by dissolving 1.4 g. III in 10 cc. 10% HCl, evapn. on the water bath and drying in the vacuum desiccator, easily sol. in water, EtOH, MeOH, less in other org. solvents. The *condensation product* of II with o-$C_6H_4(NH_2)_2$ is impure. *Tolylphenylethenylamidines* (IV), *o*-, m. 141.5°, *m*-, m. 98.5°, and *p*-, m. 90°, are prepd. by the same method. *o*-IV.*HCl*, prisms from benzene, m. 154–6°. *m*-IV.*HBr* from benzene-petroleum ether, m. 152° (decompn.). *p*-IV.*HCl* from xylene, m. 194° (decompn.), is faintly yellow. The amidines are tasteless. The salts are bitter, sol. in water, MeOH, EtOH, acetone, $CHCl_3$, moderately sol. in hot benzene and ligroin, scarcely in other org. solvents. Both amidines and salts show multicolored luminescence in polarized light. Alkaloidal reagents, with the exception of tannin, produce ppts. in the aq. salt solns.; phosphomolybdic acid, yellow; I-KI, brown; $KBiI_4$, brick-red; $KHgI_3$, greenish or yellowish; $HAuCl_4$, yellow (HCl), or brick-red (HBr). H_2PtCl_6 gives a ppt. only with III.*2HCl*. MARY JACOBSEN

***O, N, N*-Trialkylhydroxylamines.** LAUDER W. JONES AND RANDOLPH T. MAJOR. Princeton Univ. *J. Am. Chem. Soc.* **50,** 2742–7 (1928).—MeONHMe and MeI in dry Et_2O, allowed to stand 4 days, give a ppt., m. 134° ($MeONH_2MeI$); the Et_2O filtrate was treated with a little K_2CO_3 to combine with HI and with PhCNO to remove MeONHMe; distn. gives a mixt. of Et_2O and *O,N,N-trimethylhydroxylamine* (I), pptd.

as the *HCl salt*, m. 123° (46% yield); *chloroplatinate*, orange, m. 159° (decompn.); *free* **I**, from the HCl salt and concd. KOH, b. 30°; it has a fishy odor, does not reduce NHOH-$AgNO_3$ and shows no tendency to rearrange to Me_3NO. Heating **I** with concd. HCl gives $CHCl_3$, $MeNH_2$ and HCHO, the intermediate product probably being Me_2-NOH, which gives MeN:CH_2 and H_2O and finally HCHO and $MeNH_2$; the possibility that the initial reaction is the formation of Me_2NH and HCHO is excluded by the fact that at 190° Me_2NH is not decompd. by concd. HCl. *O,N-Diethyl-N-methylhydroxylamine*, prepd. in a similar manner in 20% yield, b. 79°; *chloroplatinate*, orange, m. 158°. EtI reacts with EtONHEt very slowly. Me_2CHOH and EtONHEt.HCl give $EtNH_2$.HCl, Me_2CO and EtOH. I and MeI give Me_3NOMeI, identical with that obtained from Me_3NO and MeI. C. J. West

Condensation products from acid amides and aldehydes. Constitution of the transformation products of the benzometoxazones. Erhard Glaser and Siegmund Frisch. *Arch. Pharm.* **266**, 103–16(1928).—The present study is an amplification of the investigation of nitro compds., as carried out by Glaser and others (cf. *C. A.* **20**, 2487). Simple melting together at about 100° of *m*-nitrobenzaldehyde and salicylamide yielded *2-m-nitrophenylbenzometoxazone* (I), $C_{14}H_{10}O_4N_2$, m 220° (*N-acetyl* deriv., m 116°, the *N-benzoyl, deriv.* m. 173°). This condensation is also smoothly effected in alc. soln. in the presence of a little HCl. On treating I with 50% KOH in C_5H_5N, followed by strong diln. in an excess of HCl, a phenolic polymer, m. 175°, may be sepd. Its differentiation from the cyclic form is readily effected by soln in ammoniacal alc Titherly's hypothesis that syn - and antiforms of the phenolic type exist is without foundation. The phenolic form is not a true tautomeric modification, but rather a dimeride, $C_{28}H_{20}O_8N_4$, susceptible of easy dissocn. Its *O-acetate* m. 187–8° (decompn.), the *O-benzoate* m. 161°. Attempts to methylate I with Me_2SO_4 lead to its conversion into the phenolic dimeride. It is unaffected by CrO_3 in AcOH, but yields with Br in AcOH dibromosalicylamide. Condensation of *m* nitrobenzaldehyde and benzamide was effected in alc soln. (in the presence of dil HCl) to *m-nitrobenzalbisbenzamide*, m. 224°. Similarly, the following were prepd · *o-nitrobenzalbisbenzamide*, m. 217–8°; *m-nitrobenzalbisacetamide*, m. 236–7; *o-nitrobenzalbisacetamide*, 231–2°, *m-nitrobenzalbisurethan*, m. 192 3°; *o-nitrobenzalbisurethan*, m. 179°. W. O E.

β-Phenylalanine derivatives. V. M. Rodionov and A. M. Fedorova. Tech. High School, Moscow. *Arch. Pharm.* **266**, 116–21(1928).—In continuing their studies on the β-phenylalanine derivs. the following methoxy compds. have been prepd. and characterized. Vanillin and protocatechualdehyde both are converted into veratraldehyde, on treatment with phenyltrimethylammonium hydroxide soln , in yields of 86 and 58.3%, resp. Similarly, 2,4-dimethoxybenzaldehyde was prepd. from resorcylaldehyde (yield 41.7%), and *o*-, *m*- and *p*-methoxybenzaldehydes from salicylaldehyde, *m*-hydroxy- and *p*-hydroxybenzaldehydes, resp. (yields 72 8, 88 and 66 6%, resp.). Veratraldehyde, malonic acid and abs. alc. NH_3 yield *β-amino-β-3,4-dimethoxyphenylpropionic acid* (*HCl salt*, $C_{11}H_{15}O_4N$.HCl, m. 207 8°, yield 59%). Similarly, β-amino-β-2,4-dimethoxyphenylpropionic acid was obtained in poor yield from 2,4-dimethoxybenzaldehyde, likewise the 3 monomethoxy analogs. In each case the corresponding methoxycinnamic acid appeared as by-product. *β-Amino-β-o-anisylpropionic acid* (*HCl salt*, m. 208–10°; yield 33%). *β-Amino-β-m-anisylpropionic acid* (*HCl salt*, m. 190°; yield 39%). *β-Amino-β-p-anisylpropionic acid* (*HCl salt*, m. 205°, decompn.; yield 59%). W. O. E.

Dibutyl ether as a solvent for the Grignard reagent. C. S. Marvel, A. T. Blomquist and L. E. Vaughn. Univ. of Ill. *J. Am. Chem Soc.* **50**, 2810–2(1928).—The yields of the Grignard reagent from several typical halogen compds. when Bu_2O is the solvent are nearly equal to those obtained in Et_2O MeEtCHCO$_2$H is obtained in 66% yields, $C_9H_{19}OH$ in 65% yields and cyclohexylcarbinol in 61–5% yields In many reactions it has a decided advantage over Et_2O. C. J. West

Some ethers of the cyclohexanediols. L. Palfray and S. Sabetay. Houbigant Lab., Puteaux, Seine. *Bull. soc. chim.* **43**, 895–900(1928).—Thirty-five g. dry 1,2-cyclohexanediol (pyrocatechitol) (I), m. 74°, probably a *cis-trans* mixt., was dissolved in 200 g. MeI, heated on a water bath and 150 g. freshly prepd. and dried Ag_2O added in small portions. After being heated for 9 hrs., the material was dried, washed with MeOH and distd. The 2 ethers were sepd. by repeated fractionation, though because of the proximity of their b. ps., each contained a small amt. of the other. *Mono-Me ether* of **I**, b_{15} 74–6°, n_D^{18} 1.4572, d_{18} 1.001 (cf. *C. A.* **8**, 3186; **21**, 572). *Di-Me ether* of **I**, mint-like odor, burning taste, b_{15} 65–6°, n_D^{18} 1.4460, d_{18} 0.9652. *Bis(chloromethyl) ether* of **I**, prepd. by method of Henry, b_{16} 136–7°, n_D^{21} 1.4880. In C_6H_6 soln. it reacted

vigorously with Na when heated. The product consisted of a liquid fraction (b_{15} 62–5°, n^{18}_{D} 1.4555) and a solid fraction which decompd. when distd. These are to be studied later. In the methylation of 1,3-cyclohexanediol (resorcitol) (II), a little abs. MeOH was added because of the insoly. of II in MeI. The fraction corresponding to the *di-Me ether* of II had a $CHCl_3$-like odor, a burnt-sugar taste, b_{15} 65–6°, n^{17}_{D} 1.4985, d_{17} 1.395. The fraction corresponding to the *mono-Me ether* of II had a faint aromatic odor, b_{15} 97–8°, n^{17}_{D} 1.4650. *Bis(chloromethyl) ether* of II b_{14} 144–5°, n^{17}_{D} 1.4922. From this and an excess of MeMgI was obtained the *di-Et ether* of II, burning taste, b_{15} 85–6°, n^{18}_{D} 1.4400, d_{18} 0.9127. 1,4-Cyclohexanediol (quinitol) (III) has a *cis*-form (IV), m. 101–2° and a *trans*-form (V), m. 139–40°. Methylation of III with MeI and Ag_2O, by using abs. MeOH to dissolve III, gave the *mono-Me ether* of IV, bitter taste, b_{15} 102–3°, n^{19}_{D} 1.4671, d_{19} 1.023; the *di-Me ether* of IV, strong odor, burning taste, b_{14} 67.5–8°, n^{18}_{D} 1.4440, d_{18} 0.9526; the *mono-Me ether* of V, b_{15} 102.5–3°, n^{20}_{D} 1.4649, d_{19} 1.021; the *di-Me ether* of V, b_{15} 68–9°, n^{18}_{D} 1.4430. The *bis(chloromethyl) ether* of III, b_{14} 148–9°, n^{21}_{D} (for superfused liquid) 1.4936, by reaction with iso-PrMgBr gave the *diiso-Bu ether* of III, b_{13} 122–4°, n^{19}_{D} 1.4410, d_{19} 0.8833. LOUISE KELLEY

Preparation of ethylenic ethers by cyclization of bis(chloromethyl) ethers. S. SABETAY AND G. SANDULESCO. Houbigant Lab., Puteaux, Seine. *Bull. soc. chim.* **43**, 904–6(1928).—To 3 mols pulverized Na in suspension in C_6H_6 was added drop by drop 33 g. of the bis(chloromethyl) ether of 1,2-cyclohexanediol (I). The C_6H_6 began to boil at once. After 2 hrs. the C_6H_6 layer was free from Cl. After removal of C_6H_6 and distn., there was obtained 7 g. of the ethylenic ether of I, having a mint-like odor, a burning taste, b_{20} 65.5–6.5°, n^{18}_{D} 1.4585, d_{18} 1.035. S. and S. give an easy method for the prepn. of the methylenic ether of homopyrocatechol by heating the semicarbazone of piperonal with EtONa in an autoclave for 7 hrs. (cf. *C. A.* **7**, 790), b_{14} 80–1°, n^{13}_{D} 1.5330. LOUISE KELLEY

Ether of isosafrole bromohydrin. C. MANNICH AND FRIDA SCHMITT. *Arch. Pharm.* **266**, 84–6(1928).—The by-product appearing in the prepn. of isosafrole bromohydrin by the interaction of its dibromide and AcMe (cf. Mannich, *C. A.* **4**, 1044) is *bis[α-3,4-methylenedioxyphenyl-β-bromopropyl] ether*, $C_{20}H_{20}O_5Br_2$, m. 134°, and formed apparently by the action of unchanged dibromide on the bromohydrin. The compd. is quite stable, remaining unaffected by Pd and H, or org. bases. Hot alc. KOH, however, attacks the Br, yielding apparently a diethylenic ether in the form of a viscous oil, the latter being converted by HCl into 3,4-methylenedioxyphenyl ethyl ketone. An AcOH soln. of $AgNO_3$ likewise eliminates the Br with formation of a diacetate, which on distn. is resolved into AcOH and isosafrole oxide. HBr in AcOH converts the ether into isosafrole bromohydrin. W. O. E.

Stearic aldehyde. R. FEULGEN AND M. BEHRENS. Univ. Giessen. *Z. physiol. Chem.* **177**, 221–30(1928).—The aldehydes of higher fatty acids prepd. by Krafft (*Ber.* **13**, 1413) by dry distn. of the Ca salts of fatty acids with Ca formate are shown to be polymers incapable of forming functional derivs. or of reacting with fuchsin-SO_2. The simple aldehydes may, however, be obtained by reduction of the acid chlorides in xylene at 150° in the presence of Pd catalyst with a current of H. Completion of the reaction is detd. by collecting the HCl in *N* NaOH and titrating. The product when distd. at 1 mm. solidifies in the receiver. *Stearic aldehyde*, m. 55° (Krafft's polymer, m. 63.5°); *thiosemicarbazone*, m. 111° with previous sintering. *Palmitic aldehyde thiosemicarbazone*, m. 109°. The polymeric aldehyde has the mol. wt. of a dimer and may be depolymerized by vacuum distn. A. W. DOX

Pyrogenic decomposition of mixed magnesium carbonates. Preparation of ketones. D. IVANOV. *Bull. soc. chim.* **43**, 441–7(1928).—The carbonated Mg compds. obtained by the action of CO_2 on Mg aralkyl or *n*-primary alkyl compds. at −20° (cf. *C. A.* **19**, 1694) after removal of the ether by distn. afford (1) the hydrocarbon resulting from the decompn. 2RX + Mg = R·R + MgX_2 with (2) the ketone from the secondary decompn. RCO_2MgX + RMgX = RCO·R·MgX_2 + MgO; and (3), mainly, the ketone resulting from the decompn. $2RCO_2MgX$ = RCOR + MgX_2 + $MgCO_3$, the commencement of the 3rd stage being usually marked by the liberation of CO_2. With Mg *sec* alkyl or aryl or hydroaryl compds., the yields of ketone are poor and the decompn. affords mainly the corresponding ethylenic hydrocarbon, water, CO and CO_2. In the case of the carbonated Mg aryl compds., the corresponding hydrocarbon is the chief product, and dry distn. of the corresponding Ca or Ba salts affords the same products. Since decompn. of the corresponding Mg salts at similar

temps. affords practically the same yield of ketone, the mixed Mg carbonates are regarded as true salts of Mg and probably possess the sym. structure suggested by Jolibois (*C. A.* **6**, 2741) at high as well as at low temps. (cf. *C. A.* **21**, 3893), and the decompn. is to be represented: $(RCO_2)_2Mg.MgX_2 = RCOR + MgX_2 + MgO + CO_2$. The stability of the carbonated compd. is also dependent on the nature of the halide, the temp. of decompn. being lowest with the iodides and highest with the chlorides. The reaction is, however, best effected with the chlorides or bromides, these affording cryst. carbonates, whereas those derived from *sec.*-bromides or iodides are oily products. The following ketones have been prepd. in this way, the yields and temp. of decompn. being indicated: acetone, 330–60°, 57% (59% from $Mg(OAc)_2$); Et_2CO, 340–60°, 70% (74% from the propionate); Pr_2CO, 330–40°, 70%; Bu_2CO, 360–80°, 63% (from the chloride), 50% from the bromide at 330–40°; $(iso\text{-}Am)_2CO$, 390–400°, 43% from the chloride, 35% at 370–90° from the bromide; $(iso\text{-}Pr)_2CO$, 380–90°, 35%, $(iso\text{-}Bu)_2CO$, 360°, 28%; $(MeEtCH)_2CO$, 340–50°, traces; $(PhCH_2)_2CO$, 370°, 57% (60% from PhMgOAc at 370–80°); dihexyl ketone, 390–410°, traces; Ph_2CO, 460–500°, 6% (30% from $Mg(OBz)_2$); $(p\text{-}MeC_6H_4)_2CO$, 450°, traces. The following m. ps. are recorded for the anhyd. (probably basic) Mg salts: *acetate*, 357°; *propionate*, 286°, *butyrate*, 275°; *valerate*, 258°, *isovalerate*, 224°, *benzoate*, 320°, *hexahydrobenzoate*, 492°. B. C. A.

Conjugated double bonds. VI. The coloring matter of the Chinese fruit of the gardenia. The occurrence of polyene coloring matter in the plant kingdom. RICHARD KUHN, ALFRED WINTERSTEIN AND WILLY WIEGAND. Zürich. *Helv. Chim. Acta* **11**, 716–24(1928); cf. *C. A.* **22**, 2950.—*Gardenin:* (I), $HO_2CCH{:}(CH.CMe.CH.CH)_3{:}CH\text{-}CO_2H$, the coloring matter in a no. of plants, has now been prepd. in a cryst. form (cf. *C. A.* **16**, 2503) and found to be identical with *α-crocetin* (I) (cf. *C. A.* **21**, 2474). Attempts to isolate β- and γ-crocetin from the seed of *Gardenia grandiflora* L were not successful. Many other plants are named which contain I, which is a deriv. of a tetradecaheptenedicarboxylic acid and is very closely related to bixin (II), $C_{25}H_{30}O_4$, and differs from norbixin by having one less C_5H_6 group (a hydrogenated isoprene group). A table of color reactions with various reagents which distinguish I from II is given. Polyene colors (I, II, carotin, lycopine, etc.) give an intense blue color with concd. H_2SO_4, dark blue to green addn. compds. with Br vapor, characteristic reactions with HCO_2H, Cl_2CHCO_2H, Cl_3CCO_2H, etc., but do not give (*i. e.*, I and II) addn. compds. with picric acid, showing the absence of aromatic rings. I (1.5 g.) was isolated from the finely ground, whole fruit of *Gardenia grandiflora* (1 kg.) by first removing fats with petr. ether, followed by Et_2O, extg. I by shaking 24 hrs. with 70% Me_2CO, filtering, distg. off nearly all the Me_2CO, removing oily impurities with Et_2O, neutralizing the red, aq. residue with NaOH (α-naphtholphthalein indicator), adding 1% excess NaOH, allowing to stand 3 hrs., then warming slightly, acidifying with AcOH and recrystg. the ppt. from Ac_2O. In a similar manner, except that the Me_2CO was removed *in vacuo*, a 0.07% yield of I was obtained from the petals of *Crocus luteus*. It forms a salt $C_{19}H_{20}O_4K_2$; the equivalent weight of I detd. by titration in Me_2CO soln. with 0.025 *N* alkali (α-naphtholphthalein indicator) was found to be nearly 157.1; II gave a value near to 394.2. N. A. LANGE

Saffron coloring matter. III. P. KARRER AND HARRY SALOMON. Univ. Zürich. *Helv. Chim. Acta* **11**, 711–3(1928); cf. *C. A.* **22**, 2949.—β-Crocetin and its Na salt have been purified thoroughly and analyzed. The formula for α-crocetin is $C_{17}H_{20}(CO_2H)_2$, which corrects the formula previously accepted. β-Crocetin and γ-crocetin are the mono-Me and the di-Me esters, resp., of α-crocetin. It is suggested that the developed formula is $HO_2CCH{:}CHCMe.CHCH{:}CHCMe{:}CHCH{:}CHCMe{:}CHC\text{-}HCO_2H$, the location of the Me groups remaining unproved. A. L. HENNE

Quinazolines. I. Mechanism of the reaction between formaldehyde and *p*-substituted aromatic amines in presence of acids. G. MAFFEI. Lab. Lepetit Farmaceutici, Milano. *Gazz. chim. ital.* **58**, 261–9(1928).—5-Nitro-2-aminobenzyl-*p*-nitroaniline (cf. Meyer and Stillich, *Ber.* **35**, 739(1902); Stillich. *Ber.* **36**, 3115(1903)) (6 g.) heated with abs. HCO_2H (40 cc.) for 1 hr. at 140° in a sealed tube with agitation, poured into water (200 cc.), filtered, NH_4OH added to the filtrate, the ppt. dried, pulverized, digested and washed with AcMe and recrystd. from EtOH, gave *6-nitro-2-hydroxy-3-[4-nitrophenyl]-1,2,3,4-tetrahydroquinazoline* (I), m. 207–8°. This compd. had properties identical with those of a compd. assigned a different formula by Stillich (*loc. cit.*). Condensed with Ac_2O it formed an *Ac deriv.* the properties of which were identical with those described by M. and S. for a compd. to which they assigned quite a different formula. Furthermore, with glacial AcOH it formed *6-nitro-3-[4-nitrophenyl]-3,4-dihydroquinazoline* (II), m. 243–6°, identical with that described by M. and

S. A crit. survey of previous literature in conjunction with the present expts. leads to an explanation of the *mechanism of reaction between aromatic p-substituted amines and HCHO in acid medium.* One mol. of HCHO reacts with 2 mols. of amine, forming $CH_2(NHC_6H_4R\text{-}p)_2$. The latter in acid medium then undergoes transposition to 3,6-$R(H_2N)C_6H_4CH_2NHC_6H_4R\text{-}p$. With HCO_2H this forms an intermediate compd. of the type (III), which by elimination of 1 mol. of H_2O forms compds. of the type (IV). The reaction does not proceed exclusively thus, but includes secondary reactions, such as the formation of compds. of the type $p\text{-}RC_6H_4NHMe$, which does not form by direct methylation of the amine first entering the reaction, but results from a methylation which takes place at the same time as a decompn. of the methylene-diamino deriv.

Linear dithioxanthone. C. Finzi. R. Univ. di Parma. *Gazz. chim. ital.* **58,** 269–78(1928).—$o\text{-}H_2NC_6H_4CO_2H$ (7.32 g.) in concd. HCl (17 g.), dild. with water, diazotized with $NaNO_2$ (4 g.), the mixt. poured slowly with agitation into thioresorcinol (4 g.) in aq. NaOH (9 g.), heated to 40°, let stand, heated on the water bath, filtered, the filtrate acidified with HCl, filtered, the residue washed with water and recrystd. from AcOH and boiling EtOH, yields *m-phenylenedithio-o-dibenzoic acid* (I), flesh-colored, m. 270°. Oxidized in AcOH with H_2O_2 it is transformed into the corresponding *sulfone.* I added slowly to concd. H_2SO_4 (10 cc. per g. of I) at 100°, heated 2 hrs. at 100°, cooled, poured into ice-water, the ppt. filtered, washed with aq. Na_2CO_3 or NH_4OH and then with water, and the residue recrystd. from boiling C_5H_5N or from a large vol. of $CHCl_3$, yields *dithioxanthone* (II), light yellow, m. 316°, resistant to oxidizing agents, not being attacked even by long boiling in glacial AcOH with $K_2Cr_2O_7$ or H_2O_2. Excess 30% H_2O_2 boiled with I (2 g.) in glacial AcOH (20 cc.), partly evapd., dild. with water, and the ppt. recrystd. from boiling water, yields *m-phenylenedisulfone-o-dibenzoic acid.* $m\text{-}C_6H_4(SO_2C_6H_4CO_2H\text{-}m)_2$ (III), m. 201°, is not dehydrated by concd. H_2SO_4 at 200°. II (1 g.) dissolved in concd. H_2SO_4 (12 cc.), dild. with a few drops of water until turbid, K persulfate (4 g.) added slowly with continuous agitation, let stand several hrs., poured into ice-water, filtered, washed with water, and the residue recrystd. from $PhNO_2$, yields *dibenzophenone disulfone* (IV), yellowish, blackens around 300°, m. 305°. This method of prepn. is essentially that of Ullmann and Glenck (cf. *C. A.* **11,** 2668). II (3 g.) refluxed with K (30 g.) in EtOH (300 cc.), adding Zn dust (40 g.) slowly during 2 hrs., refluxed several hrs. more until the violet color changes to yellow and then to green, filtered hot, dild. with water, partly evapd., acidified with excess HCl, filtered, washed with water, the residue (which is difficult to purify) dissolved in boiling C_6H_6, repptd. with petr. ether, washed with boiling AcOH and recrystd. from boiling xylene, yields *dithioxanthydrol* (V), yellowish, m. 224° (frothing), gives amaranth-red solns. in concd. H_2SO_4 and HNO_3. The *prepn. of diazothio ethers of thioresorcinol* was also carried out. The prepn. of *m-phenylenedithio-o-diazobenzoic acid,* $m\text{-}C_6H_4\text{-}(SN_2C_6H_4CO_2H\text{-}o)_2$ (VI), is similar to that of *m*-phenylenedithiosalicylic acid (cf. *Ber.* **28,** 3237(1895)), it being necessary only that the HCl used in the diazotization be in large excess of the NaOH used in prepg. the thiophenate. The diazo deriv. poured into the alk. thiophenol, the ppt. let stand, filtered and washed, yields VI, which is insol. in almost all solvents (except $CHCl_3$) and cannot be obtained in pure cryst. form. It is transformed into phenylenesalicylic acid by alk. solns. and by boiling EtOH. *m-Phenylenedithiodiazobenzyl alc.,* $m\text{-}C_6H_4(SN_2C_6H_4CH_2OH\text{-}o)_2$ (VII), can be prepd. not only in acid medium but (unlike other thiodiazo ethers) also in alk. medium. The diazo deriv. of $o\text{-}H_2NC_6H_4CH_2OH$ (2 mols.) poured into alk. Na *m*-dithiophenate ppts. VII, yellow, which is not decompd. by prolonged boiling in alk. medium, is difficult to purify, and is sol. only in hot $CHCl_3$, a pitchy substance being deposited on cooling.

2,3-Aminonaphthoic acid (2.63 g.) dissolved in water contg. Na_2CO_3 (1 g.), repptd. by concd. HCl (10 g.), diazotized with $NaNO_2$, aq. thioresorcinol (1 g.) and NaOH (1 g.) added, ppts. *m-phenylene[dithio-2,3-diazonaphthoic] acid*, $C_6H_4(SN_2C_{10}H_6CO_2H)_2$ (VIII), decompd. by aq. alkalies.

Resolution of racemic chlorobromoacetic acid. Hilmar Johannes Backer and Hindrik Willem Mook. State Univ., Groningen. *J. Chem. Soc.* **1928,** 2125-30; cf. *C. A.* **20,** 3686.—ClBrCHCO₂H (I), b_{11} 103 4°, b. 214.5 5° (slight decompn.), m. 31.5°, yields an *acid K* and a *normal K salt*. The elec. cond. at 25° is reported. The *brucine salt* crysts. with 2 or 3 mols H_2O and may be recrystd by shaking with 2 parts H_2O at room temp. and then mixing with 20 parts of boiling H_2O, the salt is optically pure after 5 such crystns. The salt is best decompd. by using excess NaOH and extg the brucine with $CHCl_3$. The rotation of the Na salt is $[M]_D$ 6.3°; the rotation of the free acid in H_2O is greater than that of the Na salt and of opposite sign, it depends on the concn. and is raised by addn. of strong acids. The av. value of $[M]_D$ for the undissociated acid is −28°. The dissociation const., K_{17}, is 8.1 × 10^{-2}. I (0.08 g mol./l.) in 1.38 equivs. H_2SO_4 at 25° shows no racemization after 77 hrs.; at 100° the racemization const. is k_{100} 4.5 × 10^{-2}; the racemization of the salts in neutral soln is negligible; in $CHCl_3$ the racemization of the neutral salts is much faster than in H_2O; a soln. contg. 0.15 g. of Na salt of I and 0.049 g mol. NaOH has k_{25} 9 × 10^{-2}, 0.18 g. Na salt and 0.031 g.-mol NaOH has k_{25} 4.2 × 10^{-2}, the presence of KNO_3 accelerates the racemization in alk. soln while $Ca(NO_3)_2$ causes a greater acceleration than KNO_3. C. J. West

Decomposition of acetyl peroxide and the mechanism of Kolbe's electrosynthesis. Oswald J. Walker. Univ. of Edinburgh. *J. Chem. Soc.* **1928,** 2040 5.—Fichter (*C. A.* **18,** 1438; **20,** 3135) has extended the peroxide theory to electrochem. oxidation in general; W. shows that the exptl. justification for this view is unsound and that there is no necessity to assume that Ac_2O_2 is formed during the electrolysis of acetates. The main arguments against the peroxide theory are: The thermal decompn. of Ac_2O_2, both in the pure state and in soln., does not indicate a reaction according to the equation: $Ac_2O_2 = C_2H_6 + 2CO_2$; CH_4, which is not found in the anode gases during the electrolysis of acetates, is always present among the decompn. products of Ac_2O_2, often in large amts.; peroxides have not as yet been isolated by electrochem. means, even at low temps. at which the peroxides are comparatively stable. The view that the discharged AcO ions, which must necessarily be very unstable radicals, react together to give C_2H_6 and CO_2, still affords the most satisfactory, although perhaps incomplete, explanation of Kolbe's electrosynthesis. In the interaction of these radicals some sort of momentary loose union may well take place prior to a more far-going disruption, but the assumption of the actual formation of the chem. known peroxide is unnecessary and also exptly. unsound. That a small portion of the AcO radicals might unite to form the more stable peroxide would not be surprising and this possibility is not excluded. C. J. West

Action of organomagnesium derivatives on some aliphatic dialkylamides. Marthe Montagne. *Compt. rend.* **187,** 128-31(1928); cf. *C. A.* **20,** 3280 and following abstract.—Reactions previously described by M. may be explained provisionally as follows:

$$PrCONEt_2 + MeMgI + MeI \longrightarrow PrCMe(OMgI)NEt_2MeI. \quad \begin{array}{l} PrC(OMgI)NEt_2 \\ \;\;| \\ H_2C\,|\,H\;\;I\,|\,Me \end{array}$$

$$+ 2\ MeMgI \longrightarrow \begin{array}{l} PrCMeNEt_2 \\ \;\;| \\ CH_2Me \end{array} + 2\ MgI_2 + MgO + CH_4.$$

BuBr, BuI or $PhCH_2Cl$ reacts in the same way as MeI, but less vigorously; BuBr or BuI with $PrCONEt_2$ and MeMgI gives $PrCMe_2NEt_2$ (I) and *PrCMe(CH₂Bu)NEt₂* (II). II, b_{20}

128–9°; *picrate*, m. 78–9°; *chloroaurate*, m. 54°. $PhCH_2Cl$ with $PrCONEt_2$ and MeMgI gives I and *PrCMe*[$(CH_2)_2Ph$]NEt_2 (III), b_{10} 163°; *picrate*, m. 99°; *chloroaurate*, m. 101°. The constitution of II and III, inferred from that of $PrCMe(CH_2Me)NEt_2$ is confirmed by the analysis of the bases and of their derivs.; also, the HCl salt of II gives, when heated, an ethylenic hydrocarbon, b. 161–4°, of which the vapor d. and b. p. correspond to the formula $C_{10}H_{20}$. $PrCMe(CH_2Bu)NEt_2.HCl \longrightarrow NHEt_2.HCl + PrCMe{:}CHBu$ or $EtCH{:}CMeCH_2Bu$. The equation for the reaction of an alkyl halide on $PrCONEt_2$ in the presence of MeMgI is as follows. $PrCONEt_2 + 3\ MeMgI + RX \longrightarrow PrCMe_2NEt_2 + PrCMe(CH_2R)NEt_2$; this is an aliphatic condensation analogous to the Friedel reaction. It furnishes a means for the synthesis of branched-chain tertiary bases having an asym. carbon. M. W. McPherson

Action of organomagnesium compounds on aliphatic dialkylamides. Marthe Montagne. *Compt. rend.* **186**, 874–7(1928).—MgMeI reacts with $PrCONEt_2$ to give the normal product, $PrCMe_2NEt_2$ (*C. A.* **20**, 3280), and also *γ-diethylamino-γ-methylhexane*, b_{16} 81° (*picrate*, m. 78°; *perchlorate*, m. 154°; *chloroaurate*, m. 84°; *chloroplatinate*, m. 199°), the HCl of which decomps. at 170–80° into $NHEt_2$ and γ-methyl-Δ^{β}-hexene, identical with that obtained by the dehydration of γ-methylhexan-β-ol. The new base can be synthesized from $PrCMeEtCONH_2$ by the Hoffmann rearrangement followed by diethylation of the product. Since no trace of PrCMeEtNMeEt is formed in the reaction, the interchange of radicals is improbable; it is suggested that the abnormal product occurs through the presence of free MeI in the reaction mixt. This view is supported by the exclusive production of the base when MeI (1 mol.) is added at the beginning of the reaction. B. C. A.

Mechanism of the acetal reaction. The explosive rearrangement of hydroxyethyl vinyl ether into ethylidene glycol. Harold S. Hill and Lloyd M. Pidgeon. McGill Univ. *J. Am. Chem. Soc.* **50**, 2718–25(1928); cf. Hill and Hibbert, *C. A.* **18**, 1987.—In previous work dealing with the formation of cyclic acetals from $CH{:}CH$ and poly-HO compds., the intermediate compd., *hydroxyethyl vinyl ether* (I), was assumed, which rearranged to give ethylidene glycol (II). This assumption is now verified. By the action of 315 g. Br on 125 g. paraldehyde at −12° (stirring for 10 hrs. at −10°) and the addn. of 135 g. $(CH_2OH)_2$ at −10° (stirring at room temp. for 6 hrs.), there results 80% of $BrCH_2CH(OCH_2)_2$, which may be purified by shaking with 10% NaOH; 140 g. $(CH_2OH)_2$ and 185 g. dibromoparaldehyde, heated on the steam bath for 10 hrs., give 40% of the same compd. The action of Na in Et_2O for 7 hrs. gives 56.4% of I, b_{10} 44–5°, b_{760} 140°, n_D^{17} 1.4564; I is stable when distd. from a slightly alk. soln. but is very sensitive to acids. Benzoate, b_6 133°; this shows no activity in contact with a trace of concd. H_2SO_4. Freshly prepd., pure I rearranges violently with a trace of concd. H_2SO_4, giving II; 2 cc. I, treated with a fraction of a drop of concd. H_2SO_4 with cooling, and, after the rapid reaction has taken place, slowly treated with more I, gives 90% of II. A trace of dry HBr also produces the same instantaneous rearrangement of I into II. Since the Bz deriv. does not rearrange, the HO group must play a sp. role in the transformation. The mechanism of the reaction is elaborated so as to include similar reactions such as those occurring in glucoside and polysaccharide formation. C. J West

Vinyl derivatives: their relationship to sugars and polysaccharides. Harold S. Hill. McGill Univ. *J. Am. Chem. Soc.* **50**, 2725–31(1928).—In order to show that the rearrangement of $CH_2{:}CHOCH_2CH_2OH$ into $MeCH(OCH_2)_2$ represents a general tendency toward cyclization in derivs. of this type, *hydroxypropyl vinyl ether* (I) was prepd.; this undergoes the same violent, quant. rearrangement with a trace of 50% H_2SO_4 or dry HCl, indicating that this is a general type reaction. Paracetaldehyde (132 g.), brominated at −12° with 320 g. Br, and then treated with 240 g. $CH_2(CH_2OH)_2$, gives 55% of bromoethylidenetrimethylene glycol (II), b_{10} 74–5°; with Na in Et_2O, there results 85% of I, b_{10} 64–5°. I, with a few bubbles of dry HCl or with 50% H_2SO_4, gives quant. ethylidenetrimethylene glycol (III), b. 108–10°. I (5.1 g.) and 1.6 g. MeOH, treated with HCl, give 3.5 g. III; with 3 times the quantity of MeOH, the main product is $MeCH(OMe)_2$. II (90 g.) in 250 cc. abs. Et_2O, treated with 23 g. Na, the Et_2O removed and the residue treated with 80 g. MeI, yields 69% of *methoxypropyl vinyl ether* (IV), b_{137} 75–6°. IV (5.5 g.) and 1.5 g. MeOH, treated with a trace of 40% H_2SO_4, give 1 g. $MeCH(OMe)_2$, 2 g. of an intermediate mixt. and 3 g. of the mixed *acetal*, $MeCH(OMe)OCH_2CH_2CH_2OMe$, b. 153–5°. IV and $(CH_2OH)_2$ with dry HCl give as the main products ethylidene glycol and mono-Me ether of trimethylene glycol, b_{15} 86–92°. IV and α-Me glucoside with dry HCl give ethylidene-α-methylglucose, m. 77°. The expts. support the hypothesis that vinyl derivs. are the intermediates through which transformations of this nature take place. C. J. West

Condensation of glycerol. M. Rangier. *Compt. rend.* **187**, 345–6(1928); cf. *C. A.* 7, 3113; **16**, 2038, 3224.—In view of the contradictory information in the literature, R. has studied the condensation of glycerol by heating with 2% AcONa at different temps. and times. The reaction products were acetylated, and the following acetins were isolated and analyzed: $(AcO)_4(C_3H_5)_2O$, b_2 164–5°; $(AcO)_5(C_3H_5)_3O_2$, b_2 194–5°; $(AcO)_6(C_3H_5)_4O_3$, b_2 224–5°; $(AcO)_7(C_3H_5)_5O_4$, b_2 254–5°; $(AcO)_8(C_3H_5)_6O_5$, b_2 284–5°, all of which are viscous liquids, and which were obtained in yields of 10–82 g. from 100 g. glycerol. In pushing the condensation very far, a cryst. acetin was obtained which appears to be the same as a diacetin of the homologous diglyceric alc. from dichlorohydrin, reported by Fauconnier and Sanson (see *Bull. soc. chim.* **48**, 236(1887)).

Frederick C. Hahn

Sulfur-containing derivatives of glycerol. Emil Fromm, Regine Kapeller and I. Taubmann. *Ber.* **61B**, 1353–8(1928).—The compds. (I and II) obtained by the action of $NaHSO_3$ and Na_2SO_3, resp., on epichlorohydrin (III) have hitherto been assigned the structures $ClCH_2CH(OH)CH_2SO_3H$ and $HOCH(CH_2SO_3H)_2$, structures apparently confirmed by Pazscke's observation that II is formed by boiling I with Na_2SO_3. But when I is boiled with NaOH it decomps. with loss of Na_2SO_3, identified by its reduction to SnS_2 with $SnCl_2$ and HCl by the Böttger method. S so easily split off cannot be present as a sulfonic acid but must be in a sulfite ester, *i. e.*, I must be $ClCH_2CH(OH)CH_2OSO_2H$, decompd. by alkalies into Na_2SO_3 and III which then give II. To det. whether or not II also contains S easily split off is not easy for the Na salt of II is, from its method of prepn., contaminated with Na_2SO_3, an impurity not removed when the Na salt is converted into the difficultly sol. Ba salt, since $BaSO_3$ is also difficultly sol., and all prepns. of the Na or Ba salt give the Böttger SnS_2 reaction. But if the salt of II is repeatedly evapd. with HCl, which would decomp. all the metal sulfite and any sulfite ester present, the Ba salt of the unchanged II can still be pptd. with $BaCl_2$, showing that III with a primary sulfite gives a sulfite ester and with a secondary sulfite a true di-SO_3H acid. $PhCH_2SNa$ and III give *S,S'-dibenzyl-α,α'-dithioglycerol* (IV); this with HCl, Ac_2O and BzCl gives oily products which cannot be distd. but that Ac_2O gives the *mono-Ac deriv.*, $AcOCH(CH_2SCH_2Ph)_2$ (V), was shown by oxidizing the oily V to the cryst. *disulfone*, $AcOCH(CH_2SO_2CH_2Ph)_2$ (VI). IV itself with acid $KMnO_4$ gives the corresponding *β,β'-dibenzylsulfoneisopropyl alc.* (VII). crystals with 1 H_2O, which can be converted into V by acetylation. $K_2Cr_2O_7$ and concd. acids merely remove the H_2O of crystn. but the *ketone* $CO(CH_2SO_2CH_2Ph)_2$ (VIII) was finally obtained from $CO(CH_2Cl)_2$ and $NaSCH_2Ph$ and subsequent oxidation of the oily product with $KMnO_4$. The H atoms of the CH_2 groups between the SO_2 and C:O groups in VIII are labile, as would be expected, and readily replaceable by metals and alkyl groups. VIII dissolves more readily in alc. alkalies than in alc. itself. Methylation could not be effected in alc., evidently because the sulfone is decompd. by boiling alkalies, forming $PhCH_2SO_2H$, easily identified as $(PhCH_2)_2SO_2$ when the alkali cleavage is effected in the presence of $PhCH_2Cl$. VIII does not react with the usual ketone reagents ($PhNHNH_2$, NH_2OH, $N_2H_4.H_2O$), but does form mercaptoles. Thus with $PhCH_2SH$ and HCl is obtained an oily *dibenzyl mercaptole*, oxidized to the cryst. *sulfonal* (IX), $(PhCH_2SO_2)_2C(CH_2SO_2CH_2Ph)_2$, also obtained from 2 mols. $PhCH_2SH$, $CO(CH_2Cl)_2$ and dry HCl, subsequent treatment of the oily mercaptole with 2 mols. $PhCH_2SNa$ and oxidation of the resulting tetrasulfide. IV m. 59°. VI m. 159–60°. VII m. 215° and, anhyd., 206–8°, loses its H_2O in boiling glacial AcOH or H_2SO_4 (3 parts concd. acid to 1 of H_2O) but not when heated alone 2 hrs. at 130° or refluxed in alc. NaOH. VIII m. 182°. IX m. 198°.

C. A. R.

The preparation of trinitroresorcinol and some of its salts. Antonin Majrich. Tschech. techn. Hochschule Prag. *Chemicky Obzor.* **2**, 225–7; *Chem. Zentr.* **1927**, II, 2286.—The different methods of W. Friedrich, Merz-Zetter and Escales for the prepn. of trinitroresorcinol were tested, as a result of which the best conditions for the prepn. of this compd. are described. Yields of 95% can be obtained. The following new *salts of styphnic acid* were prepd.: $Hg_2C_6HO_8N_3.9H_2O$, light orange; $Hg(C_6H_2O_8N_3)_2.18H_2O$, by the action of $Hg(NO_3)_2$ on NH_4 styphnate, yellow; $Hg(C_6H_2O_8N_3)_2.5H_2O$, by boiling aq. styphnic acid with HgO, silky; $CdC_6HO_8N_3.25H_2O$, yellow; $ZnC_6HO_8N_3.18H_2O$, yellow; $FeC_6HO_8N_3.20H_2O$, olive-green; $NiC_6HO_8N_3.20H_2O$, green; $MgC_6HO_8N_3.4H_2O$, orange. The order in which these salts decomp. when heated is: Hg, Cd, Zn, Fe, Ni and Mg.

C. C. Davis

By-products of the Gattermann aldehyde reaction. Frank Bell and Thomas A. Henry. Wellcome Chem. Research Labs., London. *J. Chem. Soc.* **1928**, 2215–27.—Thymol, $Zn(CN)_2$ and C_6H_6 were treated with HCl until it ceased to be absorbed, $AlCl_3$ was then added and HCl passed through for 4 hrs.; the resulting products were *m*-

cresolaldehyde (I), $PhCHMe_2$ (II), *p*-thymolaldehyde (*semicarbazone*, m. 226°), a small amt. of *o*-thymolaldehyde (*semicarbazone*, m. 198°) and *dithymylacetonitrile* (III), m. 205°. The action of $AlCl_3$ upon thymol gives II and *m*-cresol, from which I is derived. The yields of I and II were greatest when the yield of aldehyde was least. Carvacrol, similarly treated, gives the following products: *o*-cresolaldehyde; *4-hydroxy-3-aldehydo-5-methyl-2-isopropylphenyldicarvacrylmethane*, isolated as the *semicarbazone*, pale yellow, m. 275°; *o*-carvacrolaldehyde (*semicarbazone*, m. 180°); *p*-carvacrolaldehyde (*semicarbazone*, m. 224°); *dicarvacrylacetonitrile* (IV), m. 240°. $AlCl_3$ and carvacrol give *o*-MeC_6H_4OH and $PhCHMe_2$. Carvacrol, $CHCl_3$ and NaOH give a mixt. of the *o*-aldehyde with a little *p*-aldehyde. *o*-MeC_6H_4OH with $Zn(CN)_2$ and HCl gives a mixt. of the *o*-cresolaldehyde (*semicarbazone*, m. 248° (decompn.)) and the *p*-aldehyde (*semicarbazone*, m. 216°). No cryst. material could be isolated from the gums obtained by the action of KCN on alc. solns. of *o*-HOC_6H_4CHO, *p*-HOC_6H_4CHO or carvacrolaldehyde, either alone or when mixed with PhOH or carvacrol, resp. Thymolaldehyde, thymol and KCN give III. With $Zn(CN)_2$ and HCl there results *trithymylmethane*, m. 280°; *Ac deriv.*, $C_{37}H_{46}O_6$, m. 186°. *Tricarvacrylmethane*, m. 275°; *Ac deriv.*, m. 185°. Thymolaldehyde and thymol in abs. EtOH were treated with dry HCl, then $ZnCl_2$ was added and the mixt. boiled for 2 hrs., giving III quant.; no combination occurs when $ZnCl_2$ is omitted. III is not attacked by boiling HCl or by 50–65% H_2SO_4. Heating with EtOH-KOH gives *dithymylacetamide*, m. 243° (decompn.). III yields a *di-Ac deriv.*, m. 174°. IV yields a *di-Ac deriv.*, m. 196°. Thymolaldehyde and carvacrol or carvacrolaldehyde and thymol give *thymylcarvacrylacetonitrile*, m. 227°; *di-Ac deriv.*, m. 145°. *Tolylthymylacetonitrile*, m. 153° (*di-Ac deriv.*, m. 131°); *tolylthymylacetamide*, m. 211°; 10% HCl gives *tolylthymylacetic acid*, m. 188°. *p-Hydroxyphenylthymylacetonitrile*, m. 144°; *Me ether*, m. 106°. *o-Hydroxyphenylthymylacetonitrile*, m. 142°. *Catechylthymylacetonitrile*, m. 147–9°. *m-Hydroxyphenyldithymylmethane*, m. 165°. *o*-$O_2NC_6H_4CHO$ gives only the HCN addn. product. *m-Nitrophenyldithymylmethane*, m. 171°; *p-NO_2 deriv.*, m. 145°; *p-Cl deriv.*, m. 156°; *o-Cl deriv.*, m. 138°. C. J. West

Stereochemistry of fluorene series, citric acid, etc. III. Isomerism of citric acid. K. Nakamura. Osaka Ind. Research Inst. *J. Pharm. Soc. Japan* No. **539**, 47–9 (1927).—In paper II, it was concluded that citric acid (I) has 2 isomers, one of which is labile and is represented by the so-called hydrated form (II) (softens at 70–5°), and the other (III), m. 153°, is obtained by dehydration of II. The evidences for the existence of isomerism were the facts that I and diphenyleneglycolic acid (IV) resemble each other greatly in chem. and phys. properties; the existence of isomerism in the fluorene derivs. when 2 different substituents are located at position 9; and that III cannot be converted back to II by a simple crystn. from H_2O. Further to substantiate the former conclusions, the absorption spectra of aq. solns. of both modifications were compared. As expected, they showed entirely different absorption. In contrast to II, III showed a strong absorption in the ultra-violet region, and its aq. soln. showed a strong fluorescence in a dark room with Fe monochromatic light. X-ray studies are now being made. Nao Uyei

Preparation of β-iodoethylurethan. S. Kuroda. *J. Pharm. Soc. Japan* No. **539**, 44–7(1927).—*First Method.*—Heating of 32.5 g. $Cl(CH_2)_2OH$ and 61 g. NaI in 80 cc. EtOH gave 39 g. $I(CH_2)_2OH$ (I); 20 g. of I and about 20 g. of $COCl_2$ gave $I(CH_2)_2OCOCl$ (III); III with NH_3 gave $I(CH_2)_2OCONH_2$ (IV), m. 93°. *Second Method.*—Passing about 12 g. of $COCl_2$ into 20 g. $Cl(CH_2)_2OH$ gave $Cl(CH_2)_2OCOCl$, (V). V with NH_3 gave $Cl(CH_2)_2OCONH_2$ (VI), m. 76°. Heating 11 g. of VI and 26 g. of NaI in 40 cc. EtOH gave 7 g. of IV. Nao Uyei

Oxidation of α-monobenzoylglycerol. S. Aoyama. Tokyo Imp. Hyg. Lab. *J. Pharm. Soc. Japan* **539**, 27–39(1927).—Prepn. of α-glyceryl phosphate (I) by Fischer's method (*Ber.* **53**, 1606) and its β-isomer (II) by King's method (*C. A.* **8**, 3023) in order to study their structures led to the isolation of the same product. Since the oxidation of I or II should give an aldehyde or ketone, different in each case, this reaction was used to study the structure of *α-monobenzoylglyceric acid* (III). Oxidation of III with CrO_3, $KClO_3$ or Br_2-H_2O gave an acid or resinous products with no intermediate products, while with NaOBr, *α-benzoylglyceric aldehyde* (m. 106–10°; *semicarbazone*, decomps. 160–2°; *oxime*, m. 117–8°), *benzoyldihydroxyacetone* (*semicarbazone*, decomps. 156–8°), *α-benzoylglyceric acid* (m. 141–2°) and benzoylglycolic acid (?) were obtained. Oxidation with $MnSO_4$ or PbO_2 and HCl gave *benzoylglycolic aldehyde* (m. 32–4°, b_9 124–6°; *semicarbazone*, m. 194–5°; *oxime*, m. 78–81°). The above reactions show that the acyl group in III is in α-position and F.'s synthesis of α-glyceride is correct. N. U.

Preparation of thioglycolic and thiolactic acids by electroreduction. Erik Larsson.

Svensk Kem. Tid. **40,** 149–50(1928); cf. following abstr.—$CH_2(SH)CO_2H$(I) was prepd. from $S_2(CH_2CO_2H)_2$ and $MeCH(SH)CO_2H$(II) from $S(SCHMeCO_2H)_2$ by electrolysis with 2*N* H_2SO_4 as electrode solns. and semicylindrical Pb plates as electrodes. For I the c. d. 0.02 amp./sq. cm. and for II, 0.04. The precursors were poured into a porous cup which was placed in a beaker contg H_2SO_4 and the anode. A spiral stirrer was placed in the cathode liquor. A cooling bath was not necessary. The yield for I was 70–80% and for II 80–90%. The precursor of I was prepd. from CH_2ClCO_2Na + Na_2S and that of II from $AcCO_2H$ and H_2S. A. R. ROSE

Electrolytic reduction of dithiodiglycolic acid. ERIK LARSSON. Univ. Lund. *Ber.* **61B,** 1439–43(1928); cf. preceding abstr.—The reduction of $(SCH_2CO_2H)_2$ (I) at Pt and Pb cathodes in 2 *N* H_2SO_4 was studied with polarization and direct reduction expts. With Pb as the cathode I can be reduced practically completely to $HSCH_2CO_2H$ either at a const. cathode potential or with const. c. d. The current yields are in general somewhat larger with const. cathode potentials, but equally good current yields can be obtained by using a sufficiently small c. d., although the reduction then requires a somewhat longer time. C. A. R.

An improvement in our method for the preparation of lactic acid. V. SHAPOSHNIKOV AND A. MANTEIFEL. *Trans. Sci. Chem.-Pharm. Inst., Moskow* (Russ.) **1927,** No 18, 26–9; *Chem. Zentr.* **1927,** II, 1713.—Supplementary to a previous communication (cf. *C. A.* **21,** 4011), it is shown that extn. of albuminous substances by Ca lactate soln. is preferable to extn. with $MgSO_4$ soln. The application of wash water contg. lactic acid after complete neutralization with $CaCO_3$ is then described. C. C. DAVIS

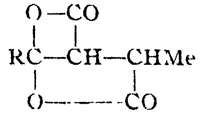
Abietic acid. G. DUPONT, J. DUBOURG AND G. ROUIN. Inst. du Pin. *Chimie et industrie* Special No., 549–51(April, 1928).—See *C. A.* **22,** 123. A. P.-C.

Tetradecenic acid from sperm oil. MITSUMARU TSUJIMOTO. Imp. Inst. Chem Techn. Tokyo. *Chem. Umschau Fette, Oele, Wachse Harze* **35,** 227(1928) – In 1923 T. isolated from sperm oil the liquid 5,6-tetradecenic acid, $CH_3(CH_2)_7CH{:}CH(CH_2)_3$-COOH, which he now wishes to name "*physeteric*" acid. P. ESCHER

The constitution of tetradecenic acid from Tsuzu oil. MITSUMARU TSUJIMOTO *Chem. Umschau Fette, Oele, Wachse Harze* **35,** 225–7(1928) —The oil was obtained from the seed of "tsuzu" or "Shirodamo" (*Tetradenia glauca,* Matsum) belonging to the family of the Lauraceae. The acid was isolated by fractionating the Me esters of the fatty acids at about 15 mm., sapong. the fraction 155–170°, sepg. the solid acids by the Pb salt-ether method, esterifying the satd. acids and collecting fraction 158–168°, which yielded 2% of the tetradecenic acid of n_D^{15} 1.4572. It was then ozonized, decomposed by H_2O at 100°, extd. with ether and the ether soln. shaken with $NaHCO_3$ soln.; this gave 3 products: (1) the ether soln., which yielded on fractionating at 15 mm. and treatment with semicarbazide-HCl 0.4 g. of white crystals of semicarbazone of capraldehyde, m. 96°, and after recrystn., m. 102–102.5°. The higher fraction yielded nearly 2 g. capric acid. (2) The $NaHCO_3$ soln., which was acidified and extd. with ether, yielded succinic acid. (3) The aq. soln. likewise yielded succinic acid and its half aldehyde. Thus the constitution was proved to be 4,5-tetradecenic acid, $CH_3(CH_2)_8CH{:}CH(CH_2)_2COOH$. T. proposes for it the name of tsuzuic acid. P. ESCHER

Constitution of protolichestearic acid. I. Y. ASAHINA AND M. ASANO. Tokyo Imp. Univ. *J. Pharm. Soc. Japan.* No. **539,** 1–17(1927).—By Et_2O extn. of *Cetraria islandica Ach. f. angustifolia, Kraplh.,* a subalpine moss in Japan, *l-protolichestearic acid* (I), $C_{19}H_{32}O_4$, m. 105°, $[\alpha]_D^{27}$ —12.71°, was isolated in 1.3% yield. It is the optical antipode of the *d*-acid found in European lichens. I, H_2 and Pt black gave *dihydroprotolichestearic acid,* $C_{19}H_{34}O_4$, m. 101°. I and $H_2NCONHNH_2$ gave the *semicarbazone,* m. about 140°. These reactions indicate the presence of a double bond in α,β-position to the CO group. Oxidation of I with $KMnO_4$ gave myristic acid, while the oxidation with O_3 and subsequent decompn. with H_2O gave besides HCO_2H and $(CO_2H)_2$, *α-hydroxypentadecylic acid,* $C_{14}H_{28}(OH)CO_2H$. Heating of I with Ac_2O resulted in an isomeric change and gave *l-lichestearic acid* (II), $C_{19}H_{32}O_4$, m. 124°, $[\alpha]_D^{26}$ —32.66°. Heating of II with 10% KOH gave with CO_2 evolution, *lichesteryl acid* (III), $C_{18}H_{34}O_3$, m. 83–4°. III has previously been prepd. by Sinnhold (*Ann.* **55,** 144), but the nature of the third O atom remained unexplained. Heating of the oxime of III with H_2SO_4 resulted in Beckmann rearrangement and gave an *acid amide* (IV) $C_{18}H_{35}(NO_3)$, m. 102°. IV and concd. HBr in a closed tube gave tridecylamine and methylsuccinic acid. The above reactions show that III has 2 possible structures $RCOCH_2CHMeCO_2H$ or $RCOCHMeCH_2CO_2H$(R = $Me(CH_2)_{12}$—). Heating of II in a vacuum at 20 mm. and 210° gave *lichesteryl lactone* (V), b. 207°, which on sapon. with KOH gave III.

V, H_2 and Pd-$BaSO_4$ gave the *dihydro deriv.* of V, m. 37–8°, while V, O_3 and H_2O gave AcOH as a decompn. product. Contrary to the view of Boehm (*Arch. Pharm.* **241**, 1) V is therefore unsatd. The above reactions show that the relation of III to V is like that of levulinic acid to angelic lactone. Hence V has one of the following 4 possible structures: (*a*) R—CH.CH:CMe.CO.O, (*b*) R—C:CH.CHMe.CO.O, (*c*) RCH.CMe:CH.CO.O, (*d*) RC:C.Me.CH_2.CO.O. But the fact that the ozonide of V gave AcOH instead of $(CO_2H)_2$ favors the structure (*a*) for V, while III should have the structure, $RCOCH_2CH(Me)CO_2H$. I, therefore, has one of the 2 possible structures, RCH.CH(CO_2H) C(.CH_2)CO.O or RCH.C(CO_2H):CMe.CO.O. Since the ozonide of I gave HCO_2H and $(CO_2H)_2$ instead of AcOH, the former structure is preferred. From the fact that I did not give III, but II gave III by sapon. with an alkali, the following structure is assigned for III.



NAO UYEI

The rate of saponification of the esters of unsaturated alcohols. M. H. PALOMAA AND ARVO JUVALA. *Ber.* **61B**, 1770 6(1928).—The rate of acid and alkali sapon. has been detd. for allyl formate, Δ^3-butenyl formate, Δ^4-pentenyl formate, vinyl acetate, allyl acetate, Δ^3-butenyl acetate, Δ^4-pentenyl acetate. The rate decreases as the no. of CH_2 groups increases for both acid and alkali sapon., the change being much larger for the latter RAYMOND H. LAMBERT

The separation of liquid and solid aliphatic acids. V. VESELY AND J. HAAS. École Polytechnique Tchèque de Brno. *Chimie et industrie* Special No., 507–15(April, 1928).—A detailed description of expts. carried out with a view to sepg. liquid from solid aliphatic acids by formation of their hydrazides. The solubilities of the hydrazides obtained from $PhNHNH_2$ in the ordinary org. solvents were found to be too similar for the end in view. With α-naphthylhydrazine there is decompn. with formation of $C_{10}H_8$; with β-naphthylhydrazine condensation takes place readily, but the solubilities of the hydrazides of the various acids did not permit of sepg. them. Secondary hydrazides (prepd. with α,α methylphenyl-, diphenyl-, di-p-tolyl- and phenyl-2,4-xylylhydrazine) gave similar results, except that stearic phenylxylylhydrazide is almost insol. in cold alc. while the corresponding oleic hydrazide is easily sol.; unfortunately the prepn. of the reagent was so difficult that sufficient could not be obtained to attempt the sepn of the 2 acids. Secondary dihydrazides were prepd. from diphenylmethanedimethyldihydrazine (I), first prepd. by J. von Braun (*C. A.* **2**, 2804, 2806), and from *diphenyldimethyldihydrazine* (II). The solubilities of oleic and stearic dihydrazides obtained from II are too similar to permit of their sepn.; but by means of the hydrazides obtained from I oleic and stearic acids can be sepd. at least as completely as by means of their amides, anilides, Pb, Ba, etc., salts. In most cases the hydrazides were prepd. *via* Strache and Iritzer (*Monatsh.* **14**, 37(1893)) by refluxing the acid about 1 hr. at 130–40° with 50% excess of the hydrazine. *Palmitic phenylhydrazide*, m. 110°, is easily sol. in alc., Me_2CO, $CHCl_3$, C_6H_6, anhyd. AcOH and benzine (b. 90–100°). *Stearic phenylhydrazide*, m. 111°, is less sol. in alc. and Me_2CO than the palmitic deriv., but is easily sol. in $CHCl_3$ and C_6H_6. *Oleic phenylhydrazide*, m. 92–3°, is difficult to prep. and is obtained only in small yield. *Erucic phenylhydrazide*, m. 82–3°, is easily sol. in org. solvents. *Brassidic phenylhydrazide*, m. 98°, is very easily sol. in alc. *10-Hydroxystearic phenylhydrazide* was obtained as a white powder, m. 106–7°, very easily sol. in alc. *Myristic phenylhydrazide*, m. 108°, is more easily sol. in org. solvents than the palmitic deriv. *Lauric phenylhydrazide*, m. 105–6°, is more easily sol. in org. solvents than hydrazides of acids contg. more C atoms. *Δ^9-Elaidic phenylhydrazide*, m. 98–9°. *Δ^{10}-Elaidic phenylhydrazide*, m. 101°. *Stearic β-naphthylhydrazide*, prepd. by heating 2 hrs. at 110–20° (at higher temps. the hydrazide is partially decompd.), m. 132–3°, is insol. in Et_2O and benzine, sol. in cold C_6H_6 and in hot Me_2CO, $CHCl_3$ and CCl_4, and slightly sol. in hot alc. *Palmitic β-naphthylhydrazide*, m. 134–5°, is a little more sol. in alc. than the stearic deriv. *Myristic β-naphthylhydrazide*, m. 139°. *Lauric β-naphthylhydrazide*, m. 136°, is a little more easily sol. in alc. than the hydrazides of acids contg. more C atoms. *Erucic β-naphthylhydrazide*, m. 106–7°, is very slightly sol. in Et_2O and boiling petrolic ether, easily sol. in Me_2CO, $CHCl_3$, CCl_4,

and anhyd. AcOH. *Brassidic β-naphthylhydrazide*, m. 121–2°, is less sol. in alc. than the erucic deriv. Attempts to prep. oleic β-naphthylhydrazide and the α-naphthylhydrazides of the higher fatty acids were unsuccessful. The phenyl- and β-naphthylhydrazides can be sapond. by heating 30 min. with 10 parts of 50% (by wt.) H_2SO_4, dilg. with an equal vol. of H_2O and heating for 30 min. *Stearic α,α-methylphenylhydrazide*, m. 78.5°, is insol. in Et_2O and benzine, easily sol. in cold C_6H_6, sol. in hot alc., Me_2CO, CCl_4 and anhyd. AcOH. *Palmitic α,α-methylphenylhydrazide*, m. 74°, has solubilities similar to those of the stearic deriv. *Myristic α,α-methylphenylhydrazide*, m. 63°, is very easily sol. in hot alc. *Lauric α,α-methylphenylhydrazide*, m. 56°. *Erucic α,α-methylphenylhydrazide*, m. 74°, is very easily sol. in alc. *Brassidic α,α-methylphenylhydrazide*, m. 69°, is less sol. in alc. than the erucic deriv. Oleic α,α-methylphenylhydrazide could not be obtained. *Stearic diphenylhydrazide*, obtained by heating 90 min. at 180–90°, m. 122.5°, is slightly sol. in hot alc. *Palmitic diphenylhydrazide*, m. 124°, is a little more sol. in alc. than the stearic deriv. *Oleic diphenylhydrazide*, m. 83–6°. *Erucic diphenylhydrazide*, m. 88°. *Brassidic diphenylhydrazide*, m. 106°. *10-Hydroxystearic diphenylhydrazide*, m. 124–5°, is easily sol. in alc., Me_2CO and $CHCl_3$. Comparison of *di-p-tolylhydrazine* prepd. *via* Lehne (*Ber.* 13, 1546) (A) and *via* Wieland (*C. A.* 3, 181) (B) showed that A is the *mono-Ac deriv. of ditolylhydrazine*, m. 171–2°, and B is true ditolylhydrazine, m. 93°. *Stearic di-p-tolylhydrazide*, m. 115–6°, insol. in Et_2O. *Oleic di-p-tolylhydrazide*, m. 79–80°, but analysis showed the product obtained was impure (N 7.30%, instead of a theoretical 5.88%). *Phenyl-2,4-xylylhydrazine*, prepd. from phenylxylylnitrosoamine by the method used by Wieland (*C. A.* 3, 181) for the prepn. of di-*p*-tolylhydrazine, m. 70–1°, easily sol. in hot alc. and in Et_2O and petrolic ether, readily oxidized on standing in the air. *Stearic phenyl-2,4-xylylhydrazide*, m. 119–20°, easily sol. in hot alc. *Oleic phenylxylyl-2,4-hydrazide*, m. 92–3°, fairly sol. in alc., insol. in Et_2O. *Stearic diphenylmethanedimethyldihydrazide*, obtained by heating the hydrazine with excess of stearic acid at 140°, m. 145–6°, is insol. in Et_2O, petrolic ether, hot Me_2CO, AcOEt, very slightly sol. in alc., very easily sol. in hot AcOH, C_6H_6, CCl_4, $CHCl_3$ and AmOH. *Palmitic diphenylmethanedimethyldihydrazide*, m. 148°. *Lauric diphenylmethanedimethyldihydrazide*, m. 147–8°, is fairly sol. in hot alc. and Me_2CO. *Oleic diphenylmethanedimethyldihydrazide*, m. 122°, is much more sol. in most solvents (especially Me_2CO and alc.) than the corresponding derivs. of satd. acids, is insol. in Et_2O and ligroin. *Δ^9-Elaidic diphenylmethanedimethyldihydrazide*, m. 127°, is slightly less sol. than the oleic deriv. *Δ^{10}-Elaidic diphenylmethanedimethyldihydrazide*, m. 136°. *Dimethyldiphenyldihydrazine* was prepd. by treating dimethylbenzidine in alc. and HCl with $NaNO_2$, sepg. the nitrosoamine (m. 211–2°), suspending in a 1:1:1 mixt. of alc., H_2O and AcOH, reducing with Zn powder, filtering and liberating the base with NaOH. Recrystg. from ligroin gives colorless needles, m. 90–1°, gradually turning yellow when exposed to the air. It is preferable to reduce by the method used by Wieland for the reduction of nitrosodi-*p*-tolylamine. The *diphenyldimethyldihydrazides of stearic and oleic acids* are more difficult to obtain than the other aryl hydrazides, and the quantities obtained were barely sufficient to make m. p. detns. Both are very sol. in alc. and cannot be sepd. by crystn. from this solvent. The stearic deriv. m. 131–2° and the oleic m. 104–5°, but the products obtained were impure. A. PAPINEAU-COUTURE

Transformation of methylpropionylcarbinol to ethylacetylcarbinol. E. VÉNUS-DANILOFF. *Bull. soc. chim.* 43, 582–6(1928).—MeCH(OH)COEt (I) is prepd. by treating Et_2CO with Br, and hydrolyzing the resulting MeCHBrCOEt on the water bath with H_2O and $BaCO_3$. I b_{761} 152.5°, b_{20} 60–0.5°, d_0^0 0.9943, d_{20}^{20} 0.9771, d_4^{20} 0.9742, MR 26.82; *semicarbazone*, m. 208–9°. I heated with alc. contg. a few drops of concd. H_2SO_4 in a sealed tube at 127–8° for 8 hrs. is transformed to EtCH(OH)COMe (II), b_{761} 147–8°, b_{27} 59–9.5°, d_0^0 0.9673, d_{20}^{20} 0.9516, d_4^{20} 0.9500, MR 27.09; *semicarbazone*, m. 216–7°. II and MeMgBr give $EtCH(OH)C(OH)Me_2$, b_{112} 122°, d_0^0 0.9764, d_{20}^{20} 0.9643, d_4^{20} 0.9627, MR 32.76. FREDERICK C. HAHN

The action of acetic anhydride and pyridine on amino acids. P. A. LEVENE AND ROBERT E. STEIGER. Rockefeller Inst. *J. Biol. Chem.* 79, 95–103(1928); cf. *C. A.* 21, 3900.—The main products of the action of Ac_2O and C_5H_5N on phenylaminoacetic acid, phenylalanine and *l*-tyrosine are CO_2 and derivs. of acetylaminoacetone of the formula $RCH(NHCOCH_3)COCH_3$. With phenylmethylaminoacetic acid there is no loss of CO_2; the reaction product is the acetylated amino acid indicating the importance for the reaction of a mobile H on the C atom (2). The following mechanism for the reaction is suggested: Under the influence of C_5H_5N enolization occurs, permitting the entry of an Ac group on the (OH)-H of the CO_2H;

there is then a migration of the Ac group to C atom (2) followed by CO_2 elimination with the formation of the ketone. Azlactones are probably formed as secondary products of the reaction. The constitution of the ketonic compds. was established by their conversion into the corresponding hydrochlorides and pyrazines. *1-Benzyl-1-acetylaminoacetone*, m. 95–95.5°. *1-Benzyl-1-aminoacetone-HCl*, m. 123–5°. *3,6-Dimethyl-2,5-dibenzylpyrazine*, m. 100–100.5°. *1-(Acetyl-p-hydroxybenzyl)-1-acetylaminoacetone*, m. 123–4°. *1-(p-Hydroxybenzyl)-1-aminoacetone-HCl*, m. 165–6° with decompn. *3,6-Dimethyl-2,5-di(p-hydroxybenzyl)pyrazine*, no m. p. given. *Acetylphenylmethylaminoacetic acid*, m. 192–3.5°. A. P. Lothrop

Salt formation with the amino acids. J. V. Dubsky. *Z. med. Chem.* **5**, 37–42; *Chem. Zentr.* **1927**, II, 914.—Critical review of the work on the formation of salts and double salts of the amino acids, particularly *glycine*. *Glycine-zinc chloride*, $ZnCl_2.3NH_2CH_2CO_2H$, crystallizes from an aq. soln. of the components, decomps. 228° and changes to an orange-red color. J. S. Reichert

Transformation of methylbenzoylcarbinol to phenylacetylcarbinol with sulfuric acid and under conditions of alcoholic fermentation. E. M. Kotchergine. *Bull. soc. chim.* **43**, 573–5(1928).—EtCOPh and Br give MeCHBrCOPh (I), b_{18} 134–5°, d_0^0 1.454, strong lachrymator. I heated with H_2O and $BaCO_3$ on the water bath, with energetic stirring, gives 69–81% BzCH(OH)Me (II), b_{13} 125–6°. II (10 g.) in 40 cc. alc. contg. 3 drops concd. H_2SO_4 in a sealed tube 8 hrs. at 120–5° gives PhCH(OH)Ac. This transformation was also realized under conditions of alc. fermentation. Frederick C. Hahn

Transformation of ethylbutyrylcarbinol to propylacetylcarbinol. E. Vénus-Daniloff. *Bull. soc. chim.* **43**, 575–82(1928).—Pr_2CO in Et_2O with Br gives 50% PrCOCHBrEt (I) and 34% of the dibromoketone (II). PBr_5 in place of Br gave 30% I. I, b_{17} 82–3°, d_0^0 1.2717, d_4^{20} 1.2433, irritates mucous membranes, II, b_{17} 100–1°, d_0^0 1.5572, d_4^{20} 1.5234. PrCOCH(OH)Et (III), b. 181–2°, b_{18} 75–6°, b_{26} 86–7°, d_0^0 0.9488, d_0^{20} 0.9326, d_4^{20} 0.9309, MR 36.06, is obtained in 43% yield by heating II on the water bath with aq. K_2CO_3, or water and freshly prepd. $CaCO_3$ or $BaCO_3$. *Semicarbazone* of III, m. 117–8°. Reduction of III, with Me_3CMgCl, gives 20% PrCH(OH)CH(OH)Et, b_{21} 117.5–8°, m. 98–9°. III is unstable during distn., forming some condensation products which upon hydrolysis with 2% H_2SO_4 28 hrs. on the water bath give PrCH(OH)COEt (IV), b. 176–7°, b_{18} 74–5°, b_{26} 83–5°, d_0^0 0.9395, d_{20}^{20} 0.9250, d_4^{20} 0.9235, MR 36.08 (*semicarbazone*, m. 121–2°) and $(PrCOCHEt)_2O$, b_{20} 151–1.5° (*semicarbazone*, m. 178–9°). III is transformed to IV by heating with 4 vols. alc. contg. a small quantity of concd. H_2SO_4, 8 hrs. at 120–30°. Frederick C. Hahn

Action of phosphorus pentachloride on ethyl tertiary-butyl ketone. Transformation of methyldimethylacetylcarbinol. Vl. Vassliev. *Bull. soc. chim.* **43**, 563–7 (1928).—$EtCOCMe_3$ and PCl_5 at 70° give $MeCHClCOCMe_3$ (I), b_{22} 84°, $d_4^{20,0}$ 0.9814, 0.9993. I heated in sealed tube with 3 mols. HCO_2K and 2 vols. MeOH, 10 hrs. at 150° gives $Me_3CCH(OH)COMe$ (II), b_{100} 108–11°, $d_4^{0,20}$ 0.9523, 0.9352, MR 36.01 (*semicarbazone*, m. 188°); and, due to the reducing action of the HCO_2K, $Me_3CCH(OH)CH(OH)Me$, m. 54°. II and MeMgBr give $Me_3CCH(OH)C(OH)Me_2$ (III), which upon oxidation with 4% $KMnO_4$ gives $Me_3C\overline{C(OH).O.C}Me_2$ (IV), m. 52°. III exists in 2 cryst. forms, isotropic crystals decompg. in the air, and crystals belonging to monoclinic syngonimetry and rhomboprismatic symmetry. II and PhMgBr give $Me_3CCH(OH)C(OH)MePh$, m. 82.5°, and $Me_3CCPh(OH)CH(OH)Me$, m. 94°. Frederick C. Hahn

Mechanism of osazone formation. B. Glassmann and Mrs. Rochwarger-Walbe. Nahrungsmittel-Trust, Odessa. *Ber.* **61B**, 1444–51(1928).—$PhNHNH_2$ in AcOH heated in the air, besides decompg. according to the equation $2PhNHNH_2 + O_2 = Ph_2NNH_2 + N_2 + 2H_2O$, also decompgs. chiefly (*in vacuo* exclusively), as the result of autoreduction, according to the equation $2PhNHNH_2 = C_6H_6 + PhNH_2 + NH_3 + N_2$. According to the Fischer formulation, osazone formation is also related with a peculiar reduction to NH_3 and $PhNH_2$ of the otherwise difficultly reducible $PhNHNH_2$, but the quantity of either NH_3 or $PhNH_2$ formed has never been detd. quant. and it has been suggested that possibly the $PhNHNH_2$ in the osazone formation in acid soln. directly oxidizes the hydrazone: $PhNHNH_2 + H_2O = PhNH_2 + NH_3 + O$. G. and R.-W. accordingly undertook to measure quant. the NH_3 formed and devised a method for detg. small quantities of NH_3 in the presence of $PhNHNH_2$. The tedious Fuchs and Nissel method (*C. A.* **21**, 1650) did not prove satisfactory for the large

series of detns. of small quantities of NH_3 which had to be made. Permutite in very dil. solns. of $PhNHNH_2$, $PhNH_2$ and NH_3 quant. adsorbs the NH_3 while the $PhNHNH_2$ and $PhNH_2$ can be quant. washed away, and the NH_3, liberated with alkali, can then be very accurately detd. colorimetrically with Nessler soln. Detn. of the NH_3 and N_2 liberated from $PhNHNH_2$ in AcOH on the H_2O bath showed that the $PhNHNH_2$ undergoes partial autoreduction to C_6H_6, $PhNH_2$, NH_3 and N_2. The NH_3 values of the osazone filtrates are quant. equal to the sum of the NH_3 resulting from the reduction of the $PhNHNH_2$ according to the Fischer formulation of osazone formation, plus that produced by the thermal autoreduction of the $PhNHNH_2$, plus that already present (presumably as the result of autoreduction) in the com. $PhNHNH_2$.

Use of toluenesulfonic esters in place of halogen esters in malonic ester syntheses. DAVID H. PEACOCK AND PO THA. Univ. of Cambridge. *J. Chem. Soc.* **1928**, 2303–5.—The reaction between $CHNa(CO_2Et)_2$ and esters of *p*-$MeC_6H_4SO_3H$ takes place much more slowly than when the halogen esters are used but they are equally suitable, in spite of a similar tendency to form dialkylmalonic esters from equimol. proportions of $CHNa(CO_2Et)_2$ and toluenesulfonic esters. $CH_2(CO_2Et)_2$ (16 g.), 18.6 g. *p*-$MeC_6H_4SO_3Me$, 2.3 g. Na and 78 cc. EtOH, boiled 4 hrs., give 13.9 g $MeCH(CO_2Et)_2$. *p*-$MeC_6H_4SO_3Et$ gives 68% of $EtCH(CO_2Et)_2$. $PhOCH_2CH_2OH$ (70 g.), 100 g. *p*-$MeC_6H_4SO_2Cl$ and 100 cc. NaOH give 90% of *β-phenoxyethyl p-toluenesulfonate*, m. 80°; with $CHNa(CO_2Et)_2$ this gives $PhOCH_2CH_2CH(CO_2Et)_2$, m. 134–6°. C. J. WEST

New method for the preparation of mono esters of diacids. E. FOURNEAU AND S. SABETAY. Pasteur Inst. *Bull. soc. chim.* **43**, 859–61(1928); cf. *C. A.* **21**, 3890.—Heating the di-*Et* esters (I) and the corresponding free acids (II) in an oil bath for 4–6 hrs., gave *mono-Et esters* of the following acids: at 130°, *oxalic* (330 g.) from 600 g. of I and 348 g. of II; at 180–200°, *succinic* (40 g.), b_{17} 146–9°, n_D^{21} 1.4323, d_{21} 1.148, from 87 g. of I and 65 g. of II; at 250°, *adipic*, b_{17} 169–70°, m. 28–9°, n_D^{20} 1.4384, d_{20} 1.081, from 55 g. of I and 42 g. of II; at 280°, *suberic* (37 g.), b_{16} 186–8.5°, m. 21–2°, n_D^{23} 1.4412, d_{23} 1.037, from 58 g. of I and 44 g. of II; at 280–300°, *sebacic* (13 g.), m. 35°, b_{15} 202–3°, from 26 g. of I and 21 g. of II. A. S. CARTER

Electrometric titration curves of dibasic acids. II. β-Substituted glutaric acids. RICHARD GANE AND CHRISTOPHER K. INGOLD. Univ. of Leeds. *J. Chem. Soc.* **1928**, 2267–72.—The titer and p_H are given for a no. of β-substituted glutaric acids; the following figures represent the values of the 1st (k_1) and 2nd (k_2) electrometric dissociation consts. and the calcd. value of the apparent distance (r) between the CO_2H groups (in A. U.): Glutaric acid, 4.60 × 10^{-5}, 5.34 × 10^{-6}, 9.22; β-Me deriv., 5.77 × 10^{-5}, 6.28 × 10^{-7}, 2.27; β-Pr deriv., 4.97 × 10^{-5}, 4.32 × 10^{-7}, 2.12; β,β-di-Me deriv., 2.03 × 10^{-4}, 5.51 × 10^{-7}, 1.57; β,β-di-Et deriv., 3.40 × 10^{-4}, 7.85 × 10^{-8}, 1.02, β,β-di-Pr deriv., 2.03 × 10^{-4}, 5.42 × 10^{-8}, 1.01; cyclopentane-1,1-diacetic acid, 1.68 × 10^{-4}, 2.63 × 10^{-7}, 1.40; cyclohexane-1,1-diacetic acid, 3.36 × 10^{-4}, 1.02 × 10^{-7}, 1.04; cycloheptane-1,1-diacetic acid, 2.78 × 10^{-4}, 1.09 × 10^{-7}, 1.10. It is surprising that the value for r for glutaric acid is so very much greater than for any of the substituted acids, but this is in keeping with the conception that the normal dibasic acids tend to a straight (zig-zag) and not a coiled configuration; otherwise the data are in general agreement with the valency-deflection hypothesis in regards to both the sequence of the compds. and the relative magnitude of the differences in respect of the property under discussion. C. J. WEST

Decomposition of the six-carbon chain of adipic acid. II. JULIUS V. BRAUN, FRITZ JOSTES AND HANS WAGNER. Univ. Frankfurt a. M. *Ber.* **61B**, 1423–31(1928); cf. *C. A.* **21**, 60; Fuson, *C. A.* **22**, 2144.—F. reports that $NHEt_2$ and its homologs with $(CH_2CHBrCO_2Et)_2$ (I) gives, along with $AcCO_2Et$, $Et_2NCH_2CH_2CO_2Et$ (II) and not $MeCH(NEt_2)CO_2Et$ (III), as v. B. and his co-workers believed. Their belief was based on the fact that the alc. (IV) formed by reduction of the substance was different from the $Et_2NCH_2CH_2CH_2OH$ (V), which had been obtained 12 yrs. before from Et_2NH and $BrCH_2CH_2CH_2OBz$ and subsequent sapon of the resulting $Et_2NCH_2CH_2CH_2OBz$; the IV and V boiled at very nearly the same temp., to be sure, but IV gave an only slightly hygroscopic methiodide, m. 188°, while V yielded a quite hygroscopic methiodide, m. 174°. Having occasion recently to prep. some of the latter methiodide, the authors found that the old prepn. must still have been somewhat impure, for 2 more crystns. raised the m. p. to 188° and the hygroscopicity diminished somewhat. Again, III gives a methiodide which, contrary to Fuson, is not oily but m. 70° and depresses the m. p. (80°) of the methiodide of the ester (II) obtained from I about 50°, and the methiodide, m. 263°, of $MeCH(NEt_2)CH_2OH$ (obtained from III) materially lowers

the m. p. of the methiodide m. 188° obtained in either of the 2 ways described above. The authors now therefore agree completely with Fuson as to the course of the decompn. of I, but while F. believes that the detg. factor is the tendency to the formation of a 4-C ring, the authors still think that it is the form of the amine reacting with the I. This conclusion was based on a comparison of the behavior of Me_2NH and piperidine on the one hand and of Et_2NH and copellidine on the other; the more disk-like form of the first 2 bases allows them to substitute both Br atoms (spatially near to each other) in I, while the branched, more 3-dimensional form of the last 2 bases either prevents or represses such a substitution; if one Br atom is substituted, there is started a transition reaction which results either in the formation of a 4-membered ring, which decomps. further, or of a double bond, which persists. The formation of a double bond with β-methyladipic acid had already been shown to be very probable and a very careful study of I has now shown that a very small quantity of the compd. $EtO_2CCH(NEt_2)$-CH_2CH:$CHCO_2Et$ is formed in this case too. A study was then made of bases which may be considered as intermediate between those given above. Below are given the no of mols. of basic propionic ester per 100 mols. of diaminoadipic ester formed by I with various amines: Me_2NH 0, MeNHEt 10, MeNHPr 20, $MeNHCHMe_2$ 200, Et_2NH 1600, $(RCH_2CH_2)_2NH$ > 1600, piperidine 0, β-methylpiperidine 200, α-methylpiperidine 570, decahydroquinoline 520, α-methyl-β'-ethylpiperidine 500. These values show clearly that it is the progressive alkylation of the α-C atoms to the N and not of the more distant atoms which is of the greatest influence on the tendency of the bases to produce decompn. III, b_{13} 69–71°, gives with Na and alc. 40% of the alc., b_{13} 56–8°. *Me β-[methylethylamino]propionate*, b_{13} 75–80°, and impure *di-Et α,α'-bis[methylethylamino]adipate*, b_{13} 160–5° (found C 59.95, H 9.50%), are obtained in the ratio 1:20 from I and MeNHEt. MeNHPr, b. 61–2°, is obtained almost quant. from $PhSO_2NHMe$ and PrI and subsequent hydrolysis with concd. HCl at 160° of the resulting $PhSO_2NMePr$, b_{13} 182–3°, which is obtained in 80% yield; HCl salt, hygroscopic, m. 150°; *phenylurea*, m. 95°. With I it gives 5 parts *Et β-[methylpropylamino]-propionate*, b_{13} 83–5° (*HCl salt*, hygroscopic, m. 111–2°; *picrate*, m. 75–7°), and 36 parts of the impure diaminoadipate. *N-Isopropylbenzenesulfonamide*, b_{13} 190°; *methylisopropylbenzenesulfonamide*, b_{13} 175° (yield, 85%). *Methylisopropylamine*, b. 50°, d_4^{19} 0.7026; picrate, m. 135°; chloroplatinate, m. 185–9°; *HCl salt*, hygroscopic, m. 77°; *Ac deriv.*, b_{13} 69–70°; *Bz deriv.*, b_{12} 144°; *phenylurea*, m. 131°; *phenylthiourea*, m. 120°. With I it yields about equal parts of *Et β-[methylisopropylamino]propionate*, b_{13} 84–6° (*picrate*, m. 85–6°), and impure diaminoadipate. β-Pipecoline, b. 125° (Bz deriv., m. 44–5°; CdI_2 compd., m. 144°), gives with I about equal parts of *Et β-β'-pipecolylpropionate*, b_{13} 111–2° (*HCl salt*, m. 167–9°; *picrate*, m. 98–9°), and *di-Et α,α'-di-β'-pipecolyladipate*, m 61–3°, mol. wt. in camphor 388 (*HCl salt*, m. 191°; *picrate*, m. 196°). α-Pipecoline gives relatively more (about 75% of the total product) of the *Et β-α'-pipecolylpropionate*, b_{14} 117–9°; *picrate*, m. 123°. *trans*-Decahydroquinoline gives about 3 parts *Et β-[decahydroquinolyl]propionate*, faintly yellow, b_{13} 155–6° (*HCl salt*, m. 165–7°; *picrate*, m. 102°), and 25% pure *di-Et α,α'-di[decahydroquinolyl]adipate*, b_{13} about 220°, m. 107–8°. C. A. R.

The influence of solvent upon the optical rotation of diethyl tartrate. T. J. HEBERT AND J. N. PEARCE. State U. of Ia. *Proc. Iowa Acad. Sci.* **34**, 218–9(1927).—Detn., of the [α] of di-Et tartrate in various mixed solvents have been made at 25° and 30°, with 2 different concns. of the ester. The solvents used were EtOH, MeOH, C_6H_6 and PhMe and the binary mixts. of each solvent with each of the remaining solvents. The mixed solvents were made on a mol. fraction basis. The [α] was found to be dependent on the compn. of the mixed solvent, upon the concn. of the ester and upon the temp. It was also found to be influenced by the nature and proportions of the 2 solvents forming the binary mixt. W. G. GAESSLER

Composition and structure of the polymer of hydrocyanic acid. E. GRYSZKIEWICZ-TROCHIMOWSKI *Roczniki Chem.* **8**, 165–74(1928); cf. *C. A.* **17**, 1424; **18**, 1985; *Bull. soc. chim.* **35**, 366(1924).—The formula of a *4,5-dicyano-1,2,3-triazole* proposed for the polymer (I) by G. is made probable by Bedel's finding that I is $C_4H_4N_4$. It was confirmed by condensation with glyoxylic acid. When prepd. by polymerization of an aq. (90%) HCN with 10% aq. NH_3 at the b. p. the product is black and the yield very small. A brown product with a yield of 20–5% is obtained by using anhyd. HCN contg. 0.5% KCN at room temp. The crystals are easily sepd. from amorphous matter by extn. with boiling ether or cold acetone. The acetone ext. is evapd. at room temp. since it reacts on heating. I recrystd. from water or aq. MeOH with bone coal, is almost colorless, m. 180° (decompn.). Ten g. powd. I was added to 5.5 g. polyglyoxal in 50 cc. hot water. The dark cryst. reaction product seps. instantaneously. Yield 80%. Recrystd.

from alc. or water, then from benzene, it m. 132.5°. The mol. wt. (ebullioscopic) is 131.0, which points to $C_6N_4H_2$. It yields on sapon. of 2 g. with 3 g. NaOH in 10 cc. 50% alc., neutralization with HNO_3, pptn. with $AgNO_3$ and liberation with HCl 1.2 g. *pyrazine-2,3-dicarboxylic acid*, m. 182–5° (decompn.). It is therefore *2,3-dicyanopyrazine*, and I is accordingly *cis-dicyanodiaminoethylene* or *diaminomaleic dinitrile*. The sapon. of I probably first leads to $HO(NH_2)C:C(NH_2)CN$ and in the second stage to NH_2CO_2H and $NCCH_2NH_2$ which finally are decompd. to CO_2, NH_3 and glycine. The polymerization probably takes place over the dimer, *diiminoethylene*. M. J.

Cyano compounds of the platinum metals. IV. Cyano-oxo salts of osmium. F. Krauss and G. Schrader. Tech. Hochschule Braunschweig. *J. prakt. Chem.* **120**, 36–40(1928).—A satd. soln. of OsO_4 in H_2O and 10% KCN give an orange soln. (I) in which the Os is 6-valent. I, acidified with H_2SO_4, boiled to destroy the excess KCN and treated with 10% $CuSO_4$, gives the grayish cryst. $Cu[OsO_2(CN)_4]$, not decompd. by acids; concd. NH_4OH gives $[Cu(NH_3)_4][OsO_2(CN)_4]$, black needles, which gives off NH_3 in the air. I, acidified with HNO_3 and treated with $AgNO_3$, gives the *compd.*, $Ag_2[OsO_2(CN)_4]$, yellow, which gives with NH_4OH the *compd.* $[Ag_2(NH_3)_4][OsO_2(CN)_4]$, dark reddish brown needles, slowly gives off NH_3 in the air. C. J. West

Tetrathiocyanogen dichloride and several compounds of the thiodiazole series derived therefrom. E. Soderback. Univ. Upsala. *Ann.* **465**, 184–210(1928).—$(SCN)_2$ and HCl in Et_2O give an immediate ppt. of $(SCN)_2.2HCl$; after 2 days this is filtered off and the Et_2O distd. off, giving *tetrathiocyanogen dichloride* (I), $S_4C_4N_4Cl_2$, m. 69–70°; this also results in C_6H_6 but the yield is much smaller than in Et_2O. HBr and I give $(SCN)_2.2HBr$. Hg and I, shaken 4 days in Et_2O, give the *compd.* $Hg[(SCN)_2Cl]_2$, m. 168–9° (yield, almost quant.). With Na_2S in H_2O this gives the *compd.* $Na(SCN)_2Cl$(II), which crysts. with 2 H_2O; the aq. soln. with a slight excess of $CuSO_4$ gives the corresponding *cupro compd.*, pure yellow. A soln. of II gradually decomps., giving the *compd.* $(SCN)_n$, decomps. above 300°. From an excess of Na_2S with the Hg compd., there results *Na persulfocyanate*, $Na_2S(SCN)_2$, which crysts. with 5 H_2O. A soln. of II, heated with NaOH, gives *Na hydroxydithiocyanate* (III), crystg. with 4 H_2O, m. 108° (decompn.); *Pb salt*, pale yellow. III, decompd. with dil. HCl (with cooling), gives *thiocyanogen hydrate*, $(SCN)_2H_2O$. Shaking III with I in 92% EtOH gives *Na dihydroxytetrathiocyanate*, $Na_2O_2(SCN)_4.5H_2O$, prisms; 4 mols. H_2O are readily lost over concd. H_2SO_4 in a vacuum. Dil. H_2SO_4 gives the free *dihydroxytetrathiocyanic acid*, decomps. above 160°. *Hydroxytetrathiocyanic acid*, yellowish white; the *Na salt* crysts. with 7 H_2O. C. J. West

Nitric oxide and carbon monoxide compounds of apparently univalent iron and nickel. Hans Reihlen, Adolf v. Friedolsheim and Walter Oswald. Tech. Hochschule Karlsruhe. *Ann.* **465**, 72–96(1928); cf. Manchot *C. A.* **21**, 869; **22**, 1134.—The original should be consulted for the 18 pages of discussion of the results. EtSH (4.8 g.) in 20 cc. 6 *N* KOH, shaken with NO, gives 95% of Et_2S, N_2O and H_2O also being formed. Ni_2SO_4 (10.85 g.) in 100 cc. H_2O and 4.8 g. EtSH in 12.9 cc. 6 *N* KOH, shaken with NO, give 84% of the *compd.*, $40NiNOSEt + Ni(SEt)_2 + 6H_2O$; a parallel expt. gave a less pure compd., $14NiNOSEt + Ni(OH)_2 + 7H_2O$. In AcOH there resulted the compd. $7NiNOSEt + Ni(SEt)_2 + 2.5H_2O$; in an alk. soln. with excess EtSH, approx. the same compd. is formed. A slightly alk. suspension of $Fe(OH)_2$ and EtSH, treated with a lively stream of CO, gives *bis[ethyl mercaptoiron carbonyl]*, $Fe_2(SEt)_2(CO)_6$, m. 67°; the mol. wt. indicates the bimol. form. C. J. West

Hydrolysis of guanidine carbonate. James Bell. Trinity College, Dublin. *J. Chem. Soc.* **1928**, 2074–7; cf. *C. A.* **20**, 2825.—A 0.1 *N* soln. of guanidine carbonate (I) was unchanged after remaining for 10 weeks at room temp. When boiled under reflux, hydrolysis took place to an appreciable extent; $CO(NH_2)_2$ was first formed and then decompn. to $(NH_4)_2CO_3$ took place to a lesser degree; no cyanate could be detected among the products of this hydrolysis. The rate of hydrolysis diminishes very much after 3 hrs.' boiling and the reaction appears to stop after 12 hrs., because of the accumulation of $(NH_4)_2CO_3$ in the soln. The hydrolysis of I in H_2O is due to its dissociation into free guanidine and H_2CO_3, the free base being hydrolyzed in the manner already described. Salts, such as the chloride, which undergo no such dissociation in H_2O, remain unchanged on boiling. C. J. West

The preparation of derivatives of guanidine from *S*-methylisothiourea sulfate. Vittorio Piovano. Istituto Naz. Med. Farm. Serono, Roma. *Gazz. chim. ital.* **58**, 245–9 (1928).—The synthetic method described is of general application, and is of advantage in that (1) guanidine derivs. are obtained directly without the necessity of eliminating secondary products; (2) there is a min. consumption of the amino compd., and (3) the use of a sealed tube is avoided. $[H_2NC(:NH)SMe]_2H_2SO_4$ (I) (10 g.) (cf. Arndt, *Ber.* **54**, 2236) in a min. of water treated with $PrNH_2$ (4.20 g.), after some hrs. heated slowly

to boiling until MeSH is no longer evolved, cooled, and the ppt. dissolved in water and pptd. by EtOH, yields 9 g. (70%) of *propylguanidine sulfate*, $[H_2NC(:NH)NHPr]_2.H_2SO_4$ (II), m. 220° (decompn.). BaO (5 g.) added to II (4 g.) in a little water to remove all H_2SO_4 but not to leave excess Ba and filtered, gives a soln. from which were prepd. 3 *propylguanidine salts: picrate*, $C_4H_{11}N_3.C_6H_3O_7N_3$, golden yellow, m. 177–8°; *chloroaurate*, $C_4H_{11}N_3.HAuCl_4$, bright red, unstable in air, m. 200° (decompn.), and *chloroplatinate*, $(C_4H_{11}N_3)_2H_2PtCl_6$, golden yellow, m. 195° (decompn.). *Piperazine* (3.20 g.) added to I (10 g.) in a min. of water, boiled until MeSH is no longer evolved, cooled and the ppt. recrystd., yields *piperazineguanidine sulfate*, $[H_2NC(:NH)N(CH_2CH_2)_2NC(:NH)NH_2]H_2SO_4$, m. 288–90° (decompn.). By treating this (10 g.) in water with BaO (5.69 g.), a soln. was obtained from which were prepd. the following 3 *piperazineguanidine salts: picrate*, $C_6H_{14}N_6(C_6H_3N_3O_7)_2$, from alc. picric acid, lemon-yellow, m. 260–70° (decompn.); *chloroaurate*, $C_6H_{14}N_6(HAuCl_4)_2$, from concd. $AuCl_3$ acidified with HCl, greenish yellow, birefringent, turns brown in air, m 243° (decompn.) and *chloroplatinate*, $C_6H_{14}N_6.H_2PtCl_6$, lemon-yellow, m. 265–8° (decompn.). C. C. Davis

Caffeidine and caffeidinecarboxylic acid. Heinrich Biltz and Hans Rakett. Univ. Breslau. *Ber.* **61B**, 1409–22(1928).—Caffeine with alkalies takes up 1 mol. H_2O to form caffeidinecarboxylic acid (I), which by loss of CO_2 gives caffeidine; this, from its monobasic character and its reactions must have the structure **II.** Whether in the formation of I the purine ring is broken between positions 1 and 2 or 2 and 3 was not known but the present work shows that it is between 1 and 2 and hence that I has the structure III. In its prepn. 2 *N* NaOH in moderate excess was used instead of $Ba(OH)_2$ and heating was avoided; by shaking with a machine, the time necessary for the reaction was reduced from more than 2 weeks to 3-4 days. From the cooled soln. the II can be pptd. directly with HNO_3 as the difficultly sol. nitrate (hitherto described as a hygroscopic substance), and from the mother liquors the I is obtained as the Cu salt by the original May and Andreasch method. II behaves as a monoacid base (with HCl, HI, HNO_3, $HClO_4$, H_2PtCl_6). With H_2SO_4 it forms a 1:1 salt, to be sure, but this is undoubtedly an acid salt. Since caffeine is monoacid through the 9-N atom and the imidazole ring of II is the same as that in caffeine, the basic nature of II is probably due to the same N atom (3 in the notation for II). The MeNH group on C atom 4 is apparently not capable of adding acids, probably because of the adjacent 4,5-double bond. In agreement with this view is the fact that I, whose 8-N atom certainly does not add acids, forms with acids salts like caffeine and II. II also forms a *complex Ag salt* $[Ag(C_7H_{12}ON_4)_2NO_3]$ with $AgNO_3$. The action of HNO_2 on II shows that the 8-N atom is secondary. The 7-MeNH group does not react with HNO_2, for *allo*-caffuric acid can in no way be nitrosated. Since I does not react with HNO_2, the CO_2H group must be on N atom 8, as shown in formula III. Similarly II can and I cannot be benzoylated. The 1st Me group which can be introduced with MeI certainly enters the same position; the 2nd Me group, which can be likewise introduced with MeI, may enter position 7 but this is not proved. Me_2SO_4 introduces only one Me group. The smooth transformation of II into 1,3-dimethylparabanic acid does not seem to harmonize with the structure given for II; it would appear to indicate that II contains a ring with two NMe groups. The explanation is doubtless that the reaction is complicated; the II splits open between positions 2 and 3, a CO_2H group is produced at 2, and this with the NHMe group at 8 forms the new ring of the parabanic acid, the N atoms at 3 and 7 being split off by oxidation at the same time. The presence of the 4,5-double bond in II can be shown by means of Cl in MeOH and H_2O; in MeOH is obtained *caffeidine-4,5-glycol di-Me ether* (IV), while with Cl water the II likewise adds two HO groups at the double bond but at the same time oxidation occurs at 2 and the MeNHCO group at 6 is split off, the product being *1-methyl-2-keto-4-methylaminotetrahydroimidazole-4,5-glycol* (V). II can be converted back to caffeine, with 50% yield, with $ClCO_2Et$ or KOCN, and, through the amide of I, into theobromine. With $CSCl_2$ is obtained a *2-thiocaffeine* (VI), which can be converted in $CHCl_3$ into the *8-Cl deriv.* (VII), and this with NaOMe gives the *8-MeO compd.* (VIII), which can be rearranged into *2-thiotetramethyluric acid* (IX) or converted with HCl into *1,3,7-trimethyl-2-thiouric acid* (X). Finally VII was converted into *1,3,7-trimethyl-2,8-dithiouric acid* (XI) and, by alkylation, into various ethers of *2-thio-8-thiocaffeine* (XII). Nitrate of II (yield, 41%), m. 215° (decompn.), soly. in boiling H_2O about 50, H_2O at room temp. about 2, boiling MeOH about 2.7, boiling AcOH about 15 (with decompn.). II, as detd. by J. Pohl, has no diuretic action and does not affect the blood pressure. *Perchlorate*, m. 220–1° (decompn.), soly. in boiling MeOH and EtOH about 8.6; *HCl salt*, m. 215° (decompn.), is not deliquescent when pure. *Bz deriv.*, m. 174°, decompd. by alkalies, stable towards dil. acids, forms no

salts with acids. *NO deriv.*, m. 155° (effervescence), quite stable towards even concd. NaOH at room temp., forms no salts with acids. *Methylcaffeidine* (3.5 g. from 5 g. II.HNO_3 and alk. Me_2SO_4), m. 86°; *perchlorate*, m. 173°, soly. in MeOH at room temp. 1.8, at the b. p. about 8. IV.*HCl* (2.5 g. from 5 g. II in cold dry alc. with Cl); free IV, m. 164°. V.*HCl*, crystals with 1 H_2O, m. 112°, belonging (according to J. Valeton) to the monoclinic holohedral class, β 116° 17′, $a:b:c$ = 1.074:1:1.480, gives $(CO_2H)_2$ when dissolved in boiling 2 *N* NaOH and then boiled a short time with AcOH. Free V, prepd. from the HCl salt with KOCN (but not with NaOH, Na_2CO_3, $Ba(OH)_2$, $PbCO_3$ or Ag_2O), m. 163° (effervescence), soly. in alc. at room temp. about 0.3, at the b. p. 1. *Amide* of I, from II and urea with HCl gas at 135–40°, m. 244–5°, gives theobromine on long boiling in mineral acids or AcOH, evapn. with concd. HCl, boiling with Na_2CO_3 and acidifying with AcOH, treating with HCl gas in alc. or heating above its m. p. VI (20–2 g. from 25 g. II. HNO_3), light yellow, sinters 203°, m. 205°, sol. in concd. mineral acids but repptd. on diln., much more bitter than caffeine and has a strong diuretic action; *perchlorate*, deflagrates on Pt, m. 239–40° (decompn.), hydrolyzed by boiling H_2O or alc. VII (6–7 g. from 8.6 g. VI), yellow, m. 186–7°, easily sol. in concd. acids. VIII (1.5–1.7 g. from 2 g. VII), m. 174°, soly. in boiling alc. about 25. IX, from VIII in MeOH at 200°, darkens 260°, m. 297–8°. X, m. 343°, apparently with decompn., sol. in alkalies and concd. mineral acids. XI (2.5 g. from 3 g. VII with boiling aq. KSH), yellow, m. 285°, soly. in boiling H_2O about 0.8, easily sol. in alkalies and repptd. by acids; *Na* and *K salts*, yellow. *Me ether* of XII (0.8 g. from 1 g. XI with alk. Me_2SO_4), m. 183°, soly. in alc. about 5. *Et ether* (0.9 g. from 1 g. XI with EtBr and KOH), light yellow, m. 156°. *Allyl ether*, yellow, m. 98°. I m. 159° (decompn.); AcOH compd., m. 127–9°; *nitrate*, m. 173° (effervescence); *perchlorate*, m. 167–8° (effervescence); *HCl salt*, m. 179° (decompn.).

Hydroxypropyltheobromine. St. Weil and St. Rozenblum(owna). *Roczniki Chem.* **8**, 175–6(1928); *Bull. pharm. inst. Poland* No. **2**, 175–6.—*sym-Ditheobromine isopropanol*, $(RCH_2)_2CHOH$, was obtained by heating 2 mols. Na theobromine with 1 of dichlorohydrin to 130°, extn. of the white compd. with dild. NaOH and washing with H_2O. It is insol. in water and org. acids, sol. in mineral acids. In a dog of 4.5 kg. 1 g. caused marked diuresis with no untoward effects. Clinical expts. showed that the diuretic effect was not greater than that of diuretin. Mary Jacobsen

Alkali cleavage of pentoses. F. Fischler and R. Boettner. Univ. Munich. *Z. physiol. Chem.* **177**, 264–9(1928).—Distn. of 1% arabinose or xylose during the gradual addn. of a soln. contg. 0.04 *M* Na_2CO_3 and 4.6% Na_2SO_4 yields a neutral distillate which gives the CHI_3 test and reacts with Schiff's reagent. Treatment of the distillate with $PhNHNH_2$ gives a mixt. of osazones which may be sepd. by gradually dilg. the EtOH soln. At a concn. of 70.5% EtOH glycolaldehyde osazone, m. 179°, seps., and at 40–5% EtOH methylglyoxal osazone, m. 145°, seps. Just as hexoses on distn. with alkali break into two 3-C chains (*C. A.* **20**, 3722), so pentoses break into one 3-C and one 2-C chain. No CH_2O, AcH or MeAc could be detected. Although the 2 products should be obtained in equal mol. proportions, the distillate contains a greater amt. of the AcCHO because of its greater volatility. The cleavage indicates a γ-oxide structure for the pentoses. The reaction probably consists first in the formation of Na arabinosate, which immediately breaks down into glyceraldehyde and glycolaldehyde. The former easily rearranges into $CO(CH_2OH)_2$, which on distn. is converted into AcCHO. A. W. Dox

The percentage formula of pentosans. Gerhard Schorsch. *Papierfabr.* **25**, *Tech.-Wiss. Teil* 576–7(1927).—The formula $(C_{10}H_{18}O_9)_n$ is advanced for pentosans based on the following evidence: (1) They never yield 100% xylan, for instance, when detd. as the furfuralphloroglucide; (2) the purest prepns. available yielded only 92.6% pentosan; and (3) no sugar other than a pentose has ever been isolated from a pentosan. The formula $2C_5H_{10}O_5 - H_2O = C_{10}H_{18}O_9$ is in accord with the exptl. results.

J. L. Parsons

Diglucosyl tetrasulfide. Fritz Wrede and Otto Hettche. Univ. Greifswald. *Z. physiol. Chem.* **177**, 298–300(1928).—Sulfides and disulfides of sugars have already been prepd. by the action of K_2S and K_2S_2 on acetobromo-sugars (*C. A.* **14**, 1546).

The octaacetate of dithioglucosyl tetrasulfide, m. 208°, $[\alpha]^{20}_D$ −306°, has now been obtained by treating tetraacetylthioglucose (I) in dry Et_2O with excess of S_2Cl_2. The reaction mixt. solidifies to a cryst. mass which can best be recrystd. by dissolving in cold $CHCl_3$ and adding a large vol. of MeOH or petroleum ether. It is practically insol. in cold EtOH, Et_2O, C_6H_6 or H_2O and is gradually decompd. by hot EtOH. The usual method of removing Ac by treatment with MeOH-NH_3 at 0° decomps. it into octaacetyldiglucosyl disulfide and S. Similar condensations of I with SCl_2 and Se_2Cl_2 were unsuccessful. A. W. Dox

Reactivity of the methylated sugars. III. The action of dilute alkali on tetramethyl-*d*-mannose. Richard D. Greene and W. Lee Lewis. Northwestern Univ. *J. Am. Chem. Soc.* **50**, 2813 25(1928).—Directions are given for the prepn. of cryst. tetramethyl-*d*-mannose, m. 50.5–1.5°, $[\alpha]^{20}_D$ 2.4° (H_2O), 27.6° (MeOH), 23.0° ($CHCl_3$) (*c* 5 in all cases). A *M* mannose soln. in 0.342 *N* $Ca(OH)_2$, allowed to stand at 35° for 200 hrs. changed in rotation from 14.3 to 0.6° and the equil. mixt. contained mannose 71.7, glucose 8.9 and fructose 16.9% with 2.5% of non-sugar substances (probably saccharinic acids). On treating 100 g. tetramethylmannose with dil. alkali, 93.5 g. of sugar was recovered, which yielded a wt. of cryst. anilides equiv. to 87.8 g. of sugar; the wt. of pure anilides sepd. from this was equiv. to 74.7 g. of sugar, of which 36.9 g. was tetramethylglucose and 37.8 g. was tetramethylmannose; no methylated ketose was formed. Evidence is presented for the presence of the monomethyl ene-diol common to tetramethylmannose and tetramethylglucose. The ring structures of the normal forms of these 2 sugars are indicated to be identical. The prediction of the ene-diol theory as applied to the action of dil. alkali upon tetramethylmannose has been confirmed. C. J. West

Synthesis of sugars. VIII. Burckhardt Helferich and Hellmut Bredereck. Univ. Greifswald. *Ann.* **465**, 166–84(1928); cf. *C. A.* **21**, 2879.—*Vicianose.*—1,2,3,4-Tetraacetylglucose (23 g.) and 10.4 g. acetobromoarabinose in 80 cc. $CHCl_3$, shaken with 10.4 g. Ag_2O, give 0.7 g. *heptaacetyl-6-β-l-arabinosido-d-glucose*, m. 158–60°, $[\alpha]^{14}_D$ 7.5° ($CHCl_3$); sapon. with MeONa gives *6-β-l-arabinosido-d-glucose*, sinters 190°, m. 210° (decompn.), $[\alpha]^{14}_D$ 56.6° (10 min. after soln.), 40.5° (after 1 hr. in H_2O); this is assumed to be identical with vicianose (Bertrand, *Compt. rend.* **143**, 832(1906)) *Melibiose.* *Tetraacetyl-α-phenol-d-galactoside*, m. 131–2°, $[\alpha]^{20}_D$ 173.3° (C_6H_6), 175.5° ($CHCl_3$), results in 2.2 g. yield from 6 g. acetobromogalactose, 20 g. PhOH and 2.5 cc. quinoline. 1,2,3,4-Tetraacetyl-β-*d*-glucose (21 g.), 6.2 g. acetobromogalactose and 2.1 cc. quinoline, heated 1 hr. on the H_2O bath, give finally 0.025 g. *octaacetyl-6-α-d-galactosido-β-d-glucose* (octaacetylmelibiose), m. 172–3°, $[\alpha]^{20}_D$ 97.2° ($CHCl_3$). *Synthesis of an acetate of a cellobiosidogentiobiose.*—(With W. Schafer and K. Bauerlein.) Heptaacetyl 6-β-cellobiosidoacetobromoglucose (2.4 g.) and 4.8 g. 1,2,3,4,β-tetraacetyl *d*-glucose with Ag_2O in $CHCl_3$ give 0.45 g. of *6′-β-cellobiosido-β-gentiobiose tetradecaacetate*, m. 239–40°, $[\alpha]^{15}_D$ −19.6° ($CHCl_3$). *Heptaacetyl-6-β-cellobiosido-2,3,4-β-triacetylglucose*, m. 233°, $[\alpha]^{15}_D$ −6.6° ($CHCl_3$), results by shaking the Br deriv. with Ag_2O in Me_2CO. *A new tetraacetyl-d-fructose.*—(With Irmgard Modrow.) Fructose (100 g.) in 600 cc. abs. C_5H_5N and 160 g. Ph_3CCl gives 31 g. *triphenylmethylfructose*, m. 160–5° $[\alpha]^{15}_D$ −26.2° (C_5H_5N, 15 min. after soln.), changing to 4.2° after 75 hrs. Ac_2O gives the *tetra-Ac deriv.*, m. 146°, $[\alpha]^{20}_D$ 42.4° ($CHCl_3$). AcOH-HBr gives 30.7% of a *tetraacetyl-d fructose*, m. 112°, $[\alpha]^{18}_D$ 51.0° ($CHCl_3$); at 18° H_2O dissolves 2.5%, which soln. shows mutarotation The penta-Ac deriv. m. 68–70°, $[\alpha]^{18}_D$ 37.1° ($CHCl_3$). Acetobromoglucose and Ag_2O give *octaacetyl-β-d-glucosidofructose*, m. 129°, $[\alpha]^{20}_D$ 14.1° ($CHCl_3$). C. J. West

Action of (quadrivalent) titanium chloride on sugar derivatives. I. New method for the preparation of α-acetochlorosugars and the rearrangement of β-methyl glucoside into its α-form. Jenö Pacsu. Univ. Budapest. *Ber.* **61B**, 1508–13(1928).—The rearrangement of β-glucosides and β-acetylsugars into their α-forms with $SnCl_4$ in abs. $CHCl_3$ recently reported on (*C. A.* **22**, 1332) is very slow at room temp. and if it is accelerated by heating slight decompn. occurs and the soln. becomes too dark for polariscopic readings. Other $CHCl_3$-sol. metal halides have accordingly been tried. $SiCl_4$ has practically no effect while $TiCl_4$ has a very powerful action which makes it possible to convert tetraacetyl-β-methylglucoside quant. and without decompn. into the α-form in 4–5 hrs. on the H_2O bath. The mechanism of the reaction is, however, apparently different than with $SnCl_4$. On adding the $TiCl_4$ the soln. does not remain clear but a lemon-yellow addn. product is formed, which is difficultly sol. in $CHCl_3$

and in great part seps. out as an amorphous ppt.; even on warming it only partially dissolves so that the course of the reaction cannot be followed polarimetrically as with $SnCl_4$. With the other sugar derivs. mentioned below, $TiCl_4$ likewise immediately forms yellow, orange to purple ppts., which, however, generally redissolve rapidly with distinct evolution of heat. These colored mol. compds. all decomp. immediately, with loss of color, on stirring with H_2O, the $TiCl_4$ remaining in the H_2O as titanic acid and the sugar deriv., completely colorless, in the $CHCl_3$. The much more energetic action of $TiCl_4$ as compared with $SnCl_4$ on the 1-C atom of the sugar derivs. is shown by its behavior with completely acetylated mono- and disaccharides. Whereas the influence of $SnCl_4$ is exhausted when the groups in the β-position on the 1-C atom have rotated after a time into the α-position and there is a quite insignificant formation of an α-acetochlorosugar by replacement of the 1-AcO group in the α-acetylsugar, $TiCl_4$ acts so energetically that the sole product is the α-acetochlorosugar. The action of $TiCl_4$ on β-acetylsugars differs from that of $SnCl_4$ in that here too there are at once formed strongly yellow halochromic compds. which, however, quickly redissolve. The rotation of the resulting clear yellow soln., *e. g.*, of β-pentaacetylmannose, is strongly shifted towards the right from the original *l*-rotation but this instantaneous change in rotation does not indicate an instantaneous rearrangement of the β- into the α-form; the new rotation value is that of the $TiCl_4$ addn. compd. since decompn. with H_2O yields the original β-deriv. unchanged. If, however, the soln. is allowed to stand a long time at room temp. or is gently refluxed 3–4 hrs. the *d*-rotation gradually increases to a max. and on working up the product the pure α-acetochlorosugar is now found in the $CHCl_3$ layer. This replacement of the 1-AcO group by Cl proceeds so smoothly in all the acetylated mono- and disaccharides studied that the reaction affords a new, very convenient method for the prepn. of α-acetochlorosugars. By means of it tetraacetyl-α-chloroglucose (I) and -mannose (II), heptaacetyl-α-chlorolactose (III) and *heptaacetyl-α-chlorogentiobiose* (IV) were obtained in cryst. form with 1 mol. $TiCl_4$ per mol. of acetylsugar. Pentaacetyl-β-salicin, $[\alpha]^{23}_D$ $-18.5°$, gives with $TiCl_4$ an orange-yellow ppt., which quickly redissolves on shaking, the orange-yellow soln. showing $[\alpha]$ 48°. At this point H_2O regenerates the unchanged β-salicin but on standing the rotation decreases (from 3.8° to 3.1° in 6 hrs.) and the color deepens (orange-red); after 24 hrs. the bordeaux-red soln. has a rotation of 2.48°, and after 4 days the soln. is almost black-red and the rotation can no longer be measured. H_2O completely discharges the color and the resulting clear $CHCl_3$ layer yields pure tetraacetyl-β-salicin chloride, m. 160°, $[\alpha]^{20}_D$ 12.02°; this same smooth replacement by Cl of the AcO group in the aglucone can be effected in 2–3 hrs. under a reflux. I (8.6 g. from 10 g. β-pentaacetylglucose), m. 73°, $[\alpha]^{20}_D$ 167.85° ($CHCl_3$). II (8 g. from 10 g. of the β-pentaacetate), m. 81°, $[\alpha]^{20}_D$ 90.58°. III (7.8 g. from 10 g. of the β-octaacetate), m. 122°, $[\alpha]^{20}_D$ 83.97°. IV, m. 142–3°, $[\alpha]^{20}_D$ 89.22°. C. A. R.

Trimethylglucose. WILFRED H. LINNELL. *J. Pharm. Soc.* **1**, 200–9(1928).—This research was instituted in an attempt to throw further light on the constitution of 2,3,6-trimethyl-γ-methyl glucoside. Various expts. now appear to indicate definitely that the trimethylglucose obtained from sucrose is different from that prepd. from methylated cellulose and from methylated lactose. The product of this reaction was isolated in the usual way and obtained as a yellow viscid sirup which deposited white silky needles on standing. The latter m. 62–4°. Attempts to recrystallize failed because of extreme soly. in all org. solvents. Analysis proved the substance to be a trimethyl-β-methyl glucoside having $[\alpha]$ $-15.5°$. W. O. E.

Depolymerization of inulin. HANS VOGEL AND AMÉ PICTET. Univ. Geneva. *Helv. Chim. Acta* **11**, 215–20(1928); cf. *C. A.* **21**, 2665.—Com. inulin (10 g.) is depolymerized by heating for 3 hrs. at 120° and 15 mm. with 15 g. of glycerol. The product is dissolved in 200 cc. MeOH, filtered and by pptn. with 300 cc. of Et_2O, 9 g. of a yellow *trifructosan* (I) is obtained, m. 165°, sol. in H_2O and slightly sol. in MeOH and C_5H_5N, $[\alpha]^{21}_D$ -83.3. I does not reduce Fehling soln. nor give an osazone, but forms fructose (II) when heated with 5% H_2SO_4. By allowing 3 g. of I and 25 cc. of Ac_2O in 25 cc. of C_5H_5N to stand for 24 hrs. and pptg. with ice H_2O, a *nonaacetate*, $C_{18}H_{21}O_{15}(C_2H_3O)_9$, is obtained, m. 91°, insol. in H_2O, Et_2O and ligroin, sol. in hot MeOH and EtOH and very sol. in PhH and $CHCl_3$, $[\alpha]^{20}_D$ $-29.58°$. Heating inulin for 6 hrs. at 140° pro-

duces 51% of a *difructosan* (III), m. 96°, sol. in H_2O, MeOH and C_5H_5N, insol. in EtOH and Et_2O, $[\alpha]^{20}_D$ −24.5–24.8°. III reduces Fehling soln. and yields II by heating with H_2O. With 20 cc. of Ac_2O in 30 cc. of C_5H_5N, 2 g. of III forms a *hexaacetate*, m. 92°, insol. in cold EtOH and Et_2O, slightly sol. in hot H_2O, EtOH and AcOH, sol. n MeOH, $CHCl_3$ and PhH, $[\alpha]^{20}_D$ −29.8°. Evapn. of the mother liquor from II gives a sirup, $[\alpha]^{20}_D$ +12.9°, which appears to be a compd. of glycerol and a *monofructosan*, identical with the *levulosan* (IV) obtained by heating levulose *in vacuo* (*C. A.* **15**, 3462). Heating 9 g. of IV for 4 hrs. at 120° and 14 mm. with $ZnCl_2$ gives a *dilevulosan* (V), m. 138–40°, sol. in cold H_2O, insol. in EtOH, Et_2O and PhH, which reduces Fehling soln. and forms a hexaacetate, m. 83–4°, $[\alpha]^{20}_D$ +6.98°; hence III and V are not identical.

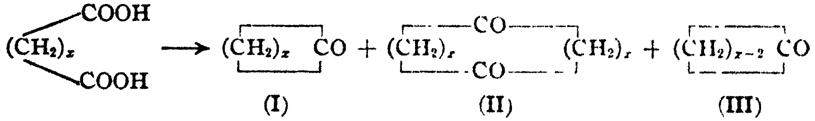
Syntheses of cyclic compounds. III. Reduction of some unsaturated cyano esters by moist aluminum amalgam. A new synthesis of mono-substituted malonic acids and of β,β,β′,β′-tetramethyladipic acid. Further evidence for the multiplanar configuration of the cycloheptane ring. Israel Vogel. Imperial Coll. Sci. Tech., London. *J. Chem. Soc.* **1928**, 2010–32; cf. *C. A.* **22**, 2369.—$Me_2C{:}C(CN)CO_2Et$, b_{14} 115°, m. 33°, reduced with moist Al-Hg, gives as the main product, $Me_2CHCH(CN)CO_2Et$, b_{16} 99°, d_4 0.9862, 0.9481 and 0.9261 at 19.2°, 62.4° and 86.8°, γ 31.49, 27.60, 25.32 for 23.3°, 61.8° and 86.6°, mean parachor, 374.8 (hydrolysis gives $Me_2CHCH(CO_2H)_2$, m. 87–8°), and *Et α,δ-dicyano-β,β,γ,γ-tetramethylbutane-α,δ-dicarboxylate*, viscid, reddish brown oil, the *amide* of which m. 95°; hydrolysis gives β,β,β′,β′-tetramethyladipic acid, m. 207°, a most convenient mode of prepg. this acid. Condensation of $Me_2C{:}C(CN)CO_2Et$ with KCN in EtOH and hydrolysis gives 60% of $HO_2CCH_2CMe_2CO_2H$, m. 141°; Et ester, b_{15} 101°, $d_4^{22.7}$ 0.9945, $n_D^{22.7}$ 1.4209. Cyclopentanone, $b_{761.5}$ 129.5°, $n_D^{16.0}$ 1.4383, d_4 0.9158, 0.9099, 0.8871 at 16.4°, 62.8°, 86.4°, γ 34.08, 29.04, 26.40 at 18°, 61.6° and 85.4°, mean parachor, 214.2. $(CH_2)_4C{:}C(CN)CO_2Et$ (I), on reduction with moist Al-Hg, gives as the main product *Et dl-cyclopentylcyanoacetate* (II), b_{13} 129°, d_4 1.0263, 0.9936, 0.9714 at 17.7°, 61.6° and 86.2°, γ 34.99, 30.87, 28.58 at 17.7°, 61.2° and 86.4°, mean parachor 430.1; a 2nd product consists of a very viscid, reddish brown oil, whose bimol. character was detd. by mol. wt. detns. in camphor; it appears to be a cyclic structure. Hydrolysis of II gives *cyclopentylmalonic acid*, m. 165° (decompn.). Condensation of I with EtOH-KCN, followed by hydrolysis, gives $C_4H_8C(CH_2CO_2H)CO_2H$, m. 160° (81% yield); the *anhydride* b_{13} 135–7°, m. 32°; the *anilic acid* m. 169°, decomps. 170°. The *Et ester* b_{13} 129°, $d_4^{20.2}$ 1.0412, $n_D^{20.2}$ 1.4477. Cyclohexanone, b_{15} 47°, d_4 0.9492, 0.9116, 0.8902 at 15.7°, 61.8° and 86°, γ 34.81, 29.84 and 2711 at 17.3°, 61.6° and 86.4°. Reduction of $(CH_2)_5C{:}C(CN)CO_2Et$ (100 g.) gives 85 g. of *Et dl-cyclohexylcyanoacetate*, b_{14} 145°, d_4 1.0221, 0.9901, 0.9690 at 18.5°, 61.2° and 86.4°, γ 35.84, 31.60, 29.36 at 17.3°, 61.8° and 85.6°, $n_D^{18.5}$ 1.4612 (hydrolysis gives $(CH_2)_5CH(CO_2H)_2$); there also results 6 g. of the *dicyano ester*, $C_{22}H_{32}O_4N_2$, m. 87°. Cycloheptanone, b_{10} 71°, d_4 0.9507, 0.9160, 0.8954 at 18.6°, 61.7°, 86.8°, γ 35.38, 30.80, 27.96 at 19.9°, 61.6° and 86.4°, mean parachor, 288; condensation with $NCCH_2CO_2Et$ gives 31% of *Et cycloheptylidenecyanoacetate*, b_{12} 160°, d_4 1.0564, 1.0219, 1.0037 at 16.3°, 61.6° and 85.6°, γ 37.70, 33.60, 31.37 at 18.6°, 62.0° and 85.4°, $n_D^{13.6}$ 1.5003; reduction gives a small amt. of the *dicyano ester*, $C_{24}H_{36}O_4N_2$, m. 74°, and, as the principal product, *Et dl-cycloheptylcyanoacetate*, b_{11} 149°, d_4 1.0209, 0.9898, 0.9704 at 19.7°, 61.8° and 86.6°, γ 35.96, 32.05 and 29.74 at 21.3°, 61.8° and 86.0°, n_D^{19} 1.4664; hydrolysis gives *cycloheptylmalonic acid*, m. 164.5° (decompn.). $(CH_2)_6C(CO_2H)CH_2CO_2H$, m. 159°, yields an *anhydride*, b_{13} 166°, m. 16° and an *anilic acid*, m. 159°, decomps. 160°. *trans*-β-Decalone, b_{12} 106°, d_4 0.9802, 0.9493, 0.9331 at 17.9°, 62.2° and 85.3°, γ 36.64, 32.45, 30.38 at 19.3°, 61.8° and 85.1°; *Et trans-decahydro-β-naphthylidenecyanoacetate*, b_{14} 197°, d_4 1.0523, 1.0239, 1.0091 at 19.4°, 62.3° and 85.0°, γ 37.37, 33.94, 32.07 at 21.6°, 61.8° and 850°, $n_D^{19.4}$ 1.5108; reduction gives principally *Et trans-dl-decahydro β-naphthylcyanoacetate*, b_{12} 186°, d_4 1.0302, 1.0011, 0.9861 at 19.9°, 62.2° and 84.8°, γ 36.32, 32.81 and 30.76 at 20.1°, 60.8° and 84.1°, $n_D^{19.3}$ 1.4805. Hydrolysis gives *trans-decahydro-β-naphthylmalonic acid*, m. 122° (decompn.). Et benzylidenemalonate, b_{14} 196°, d_4 1.1049 (supercooled), 1.0708, 1.0528 at 18.5°, 61.4° and 84°, γ 38.70, 34.42, 32.17 at 19.8°, 61.2° and 84.3°. Et benzylmalonate, b_{14} 163°, d_4 1.0761, 1.0433, 1.0231 at 19.7°, 61.2° and 85.0°, γ 35.54, 31.39 and 29.18 at 20.5°, 61.2° and 83.5°. **IV. The catalytic decomposition of suberic acid and the preparation of suberone directly from mixtures of suberic and azelaic acids.** *Ibid* **2032–5**.—Heating an intimate mixt. of 100 g. suberic acid, 100 g. Fe filings and 5 g.

of finely powd. crystd. $Ba(OH)_2$ at 280–90° gives 40% of suberone. The mixt. of azelaic and suberic acids obtained by the oxidation of ricinoleic acid with HNO_3 also gives a good yield of suberone, together with a relatively small amt. of a liquid the exact compn. of which has not been elucidated. C. J. West

Δ^3-Cyclohexenol. S. Sabetay and L. Palfray. Houbigant Lab., Puteaux, Seine. *Bull. soc. chim.* **43,** 906–9(1928); cf. *C. A.* **19,** 1857.—Δ^3-Cyclohexanol (I) was prepd. by heating 27 g. of 4-chlorocyclohexanol (II) with 5 g. Na wire in dry Et_2O for 2 days, removing the Et_2O and fractionating the liquid. I is a rather viscous oil with a bitter, burning taste, b_{14} 67–8°, n_D^{20} 1.4627, d_{20} 0.9425; phenylurethan, m. 82° (cf. Baeyer, *Ann.* **278,** 97(1893)). By passing HCl into a mixt. of trioxymethylene and **II,** there was obtained the *chloromethyl ether* of II, b_{15} 117.5°, n_D^{20} 1.4942. *Et ether* of **II,** b_{16} 84–5°, n_D^{20} 1.4622, d_{20} 1.028. II, left in contact with powd. KOH in Et_2O, either cold or boiling, is transformed only partially into cyclohexenol. *Chloro-4-cyclohexanone* (III), by oxidation of II with chromic mixt., bitter taste, b_{17} 95°, n_D^{20} 1.4867; *semicarbazone,* m. 191°. Louise Kelley

Some cyclohexyloxy derivatives. L. Palfray and S. Sabetay. Houbigant Lab., Puteaux, Seine. *Bull. soc. chim.* **43,** 900–3(1928).—Small portions of $C_6H_{11}OCH_2Cl$ (I) were added to an excess of MeONa (prepd. from powd. Na and MeOH in boiling PhMe), the mixt. was boiled until the filtered liquid contained no Cl, the NaCl sepd., the PhMe removed, and the liquid distd. *in vacuo.* The product, *methoxymethyl cyclohexyl ether,* mint-like odor, burning taste, b_{15} 61.5–2.5°, n_D^{17} 1.4387, n_D^{16} 1.4391, d_{16} 0.9375. By the same method, from the bis(chloromethyl) ether of 1,4-cyclohexanediol was obtained its *bis(methoxymethyl) ether,* burning taste, n_D^{17} 1.4490, d_{17} 1.038, b_{13} 121.5–2°. I with Ac_2O and AcONa gave *cyclohexyloxymethyl acetate,* fruity odor, b_{13} 96.5–7°, n_D^{15} 1.4465, d_{15} 1.022. From 75 g. of I, treated with 52 g. dry CuCN and heated on the oil-bath to boiling for 5 hrs., was obtained 36 g. *cyclohexyloxyacetonitrile* (II), penetrating odor, b_{15} 102–3°, n_D^{18} 1.4561, d_{18} 0.9825. *Cyclohexyloxyacetone* (8 g. from 13.9 g. II and an excess of MeMgI in Et_2O), agreeable odor, burning taste, b_{17} 98–8.5°, n_D^{17} 1.4522, d_{17} 0.9686. *α-Cyclohexyloxyacetophenone,* from II and PhMgBr, rather viscous oil, bitter taste, b_{14} 178°, n_D^{20} 1.5365, d_{20} 1.071. *s-Cyclohexyloxyphenylacetone,* from II and BzMgCl, bitter taste, b_{14} 185–6°, n_D^{21} 1.5200, d_{21} 1.044. *Me cyclohexyloxyacetate* (18 g. from 20 g. II and MeOH satd. with HCl), agreeable odor, bitter, burning taste, b_{16} 110°, n_D^{20} 1.4508, d_{20} 1.034. Attempts to reduce II with Pt black and H or with $SnCl_2$ in Et_2O satd. with HCl gave no satisfactory results. Louise Kelley

Carbon rings. XI. The 10-, 11-, 20- and 22-membered C rings and the formation of aliphatic ketones as well as the cyclic ketones obtained on decomposition of the metallic salts of polymethylenedicarboxylic acids. L. Ruzicka, M. Stoll and H. Schinz. Utrecht Univ. *Helv. Chim. Acta* **11,** 670–86(1928); cf. *C. A.* **22,** 2928.—On distn. of the salt of a polymethylenedicarboxylic acid the following might be formed:



(I) (II) (III)

$$H(CH_2)_xCOMe + H(CH_2)_xCO(CH_2)_xH + Me(CH_2)_{x-1}CO(CH_2)_xCO(CH_2)_{x-1}Me$$
(IV) (V)

Attempts were made to isolate as many of these compds. as possible. Since the yields of ring ketones with 9 or more members is very small, it was impossible to obtain sufficient starting material to give an amt. of compd. **III** sufficient for identification; it was not possible to ascertain with certainty if aliphatic ketones of type V are obtained simultaneously with 8- or 9-membered ring ketones, since the former do not form difficultly sol. semicarbazones. Compds. of the type **II** and **IV** were identified in each case. A table of yields of these various types obtained on distn. of dibasic acids from C_8 to C_{19} is given. *Cyclodecanone* (cf. *C. A.* **20,** 1792) prepd. by heating 1200 g. $(CH_2)_9(CO_2H)_2$ to decompn. (350–500°), collecting the distillate in xylene and finally by condensation with CO_2 + Et_2O cooling, was fractionated at 13 mm. and finally at 0.1 mm.; it gave a 3 g. yield of the *semicarbazone,* m. 205–7°, which was converted to the ketone, a colorless oil, b_{13} 106–7°, and which on standing at 10° gave crysts., m. 28°, d_4^{20} 0.9654, n_D^{30}

1.4782, M_D 45.57. The fraction $b_{0.1}$ 190–250° (130 g.) yielded 45 g of the *semicarbazone* (m. 228°) of cycloeicosan-1,1-dione, from which 15 g. of the diketone (VII) was obtained by hydrolysis with $H_2C_2O_4$; the diketone b_3 193°, crysts. from EtOH, m. 49–51°, d_4^{59} 0.9232, n_D^{59} 1.4662, M_D calcd. for $C_{20}H_{36}O_2$ 92.43, found 92.53; the *dioxime* forms crystals from EtOH, m. 147–8°. When 3 g. VII, 1 g. BzH and 0.8 g. Na in 40 cc. EtOH are allowed to stand for 2 weeks, dissolved in Et_2O, the NaOH removed by washing with H_2O, the Et_2O evapd., the residue steam-distd. to remove excess BzH, dissolved in Et_2O, washed with Na_2CO_3, dried over Na_2SO_4, the Et_2O evapd., heated with 2 g. $NaHSO_4$ for 1 hr. at 200°, dissolved in 30 cc. glacial AcOH, treated with O_3 for 8 hrs., CrO_3 added equiv. to 1 mol. O_2, treated with dil. HCl, extd. repeatedly with Et_2O, esterified with 10 cc. MeOH and 2 g. concd. H_2SO_4, 2 g. of *di-Me 9-ketooctadecane-1,18-dicarboxylate* is obtained, $b_{0.1}$ 210–30° and m. 59–60°; hydrolysis of this ester with alc. KOH, then acidifying and extg. the pptd. acid with PhH followed by reduction with Zn-Hg by Clemmensen's method gave *octadecane-1,18-dicarboxylic acid* (XII), m. 119–21°. On heating 3 g. VII with 25 g. Zn-Hg, 5 cc. concd. HCl and 10 cc. H_2O for 13 hrs. at 130°, extg. with Et_2O, washing with Na_2CO_3 and H_2O, evapg. the Et_2O and treating with $NH_2NHCONH_2$, it gave 3.1 g. of the *disemicarbazone* which was washed with EtOH in which it is almost insol.; the mother liquors were fractionally recrystd. and gave 0.3 g. of *cycloeicosanone semicarbazone*, m. 179–80°, hydrolyzed with 15% HCl to *cycloeicosanone* (VIII) ($C_{20}H_{38}O$), oil $b_{0.3}$ 170–1°, m. 58–9°. *Nonodecane-1,19-dicarboxylic acid* or *Japansäure* (IX), $(CH_2)_{19}(CO_2H)_2$, was obtained when Japan wax was hydrolyzed with alc. KOH, the acids thus obtained esterified (with EtOH and H_2SO_4) and then fractionated at 0.2 mm. to 0.5 mm.; it m. 112–3°; the *di-Me ester*, m. 57–8°; the Th salt on distn. gave VIII, proving the presence of $(CH_2)_{19}(CO_2H)_2$ in this wax (cf. *C. A.* 2, 801); no evidence was obtained for the presence of heptadecane-1,17- or octadecane-1,18-dicarboxylic acids in Japan wax. Electrolysis of a mixt. of the Na salt of 1-octenoic-8-acid (14 g.) and the acid ester of tetradecane-1,14-dicarboxylic acid (5 g.) gave *1-docosenoic-1-acid* which on oxidation with O_3 yielded X as follows: $CH_2{:}CH(CH_2)_5CO_2H + MeO_2C(CH_2)_{14}CO_2H \longrightarrow CH_2{:}CH(CH_2)_{19}CO_2Me \longrightarrow (CH_2)_{19}(CO_2H)_2$. *Cycloundecanone* (X), $C_{11}H_{20}O$ (0.8 g.) was obtained by dry distn. at 300–450° of 810 g. of the Y salt of $(CH_2)_{10}(CO_2H)_2$, dissolving the distillate in Et_2O, drying with Na_2SO_4, distg. at 10 mm. into fractions (*a*) 65–80°, (*b*) 80–100°, (*c*) 100–20°, (*d*) 120–50° and a residue (*e*), the semicarbazones in *b*, *c* and *d* were isolated, then hydrolyzed with $H_2C_2O_4$, the aliphatic ketones removed with $NaHSO_3$, washed with Et_2O, then converted to the *semicarbazone* (1.5 g.) which was recrystd. from EtOH and m. 202–3°; hydrolysis of the semicarbazone gave X which has an odor resembling camphor, m. 9–10°, d_4^{17} 0.9466, n_D^{17} 1.4786, M_D 50.32. The residue *e* was fractionated and the portion b_1 190–250° gave 8 g. of *cyclodocosane-1,12-dione* (XI), $C_{22}H_{40}O_2$, which was isolated as the *semicarbazone*, m. 228–30°, hydrolysis of which gave the diketone (XI), m. 55–6°, b_1 230°, d_4^{61} 0.9114, n_D^{61} 1.4633, M_D 101.6; *dioxime*, m. 151–3°; reduction (cf. formation of XII) yields *eicosane-1,20-dicarboxylic acid*, $(CH_2)_{20}(CO_2H)_2$, m. 120–2°, with the *di-Me 11-eicosanone-1,20-dicarboxylate*, $C_{24}H_{44}O_5$, m. 68–70°, as the intermediate product. As by-products in the prepn. of cyclodecanone, the following ketones were isolated with $NaHSO_3$ and converted to the following *semicarbazones: Me nonyl*, m. 115°; *Me decyl*, m. 104–5°; *Me undecyl*, m. 115–7°; *Me tetradecyl*, m. 117–8°; *Me hexadecyl*, m. 114–6°; and *Me heptadecyl*, m. 117–9°. **XII. The preparation of methylated 14-, 15- and 17-membered cyclic ketones.** L. RUZICKA, H. SCHINZ AND M. PFEIFFER. *Ibid* 686–700.—Since muscone is a 1-methylcyclopentadecan-3-one, attempts were made to prep. similar cyclic ketones with the Me group in a position 1, 2, 3 and 4 to the CO group and to compare the musk odors of such compds. The method of prepn. consisted in heating the Th or Y salts of polymethylenedicarboxylic acids and it was found that only those compds. with the Me group in position 3 or 4 yielded cyclic ketones. *1,3-Dimethylcyclotridecan-2-one* (5.4 g.) does not have a musk odor and was prepd. by destructive distn. of 173 g. of the Th salt of tetradecane-2,13-dicarboxylic acid (from the Na salt in H_2O and $Th(NO_3)_4$); the distillate was then redistd. at 12 mm., converted to semicarbazone in MeOH, which was sepd. and hydrolyzed to the ketone with concd. $H_2C_2O_4$; it b_{12} 130° – b_1 170°. An attempt to prep. 1-methylcyclotridecan-3-one from the Th salt of 2-methyldodecane-1,12-dicarboxylic acid was not successful, yielding a mixt. of products which were not completely sepd. and did not have a musk odor; 1-methylcyclotetradecan-2-one could not be prepd. from the Y salt of tetradecane-1,13-dicarboxylic acid and the product of distn. did not have a musk odor. *1-Methylcyclotetradecan-4-one*, m. 28–9°, which has a musk odor was prepd.

by heating to 170–80° the Y salt of 3-methyltridecane-1,13-dicarboxylic acid (133 g.); the 59 g. of product thus obtained was fractionated as follows: (*a*) 10 g., b_{12} 65–130°; (*b*) 4 g., b_{12} 130–50°; (*c*) 2.2 g., b_1 120–40°; (*d*) 5.5 g., b_1 140–60°; (*e*) 2.8 g., b_1 160–80°; all of these fractions were converted to the *semicarbazone* (*d* yielding the most), m. 182–3°; from the mother liquors the *semicarbazone* of *Me ω-methyltridecyl ketone* was obtained, m. 118–9°. An attempt to prep. 1-methylcyclopentadecan-2-one from the Th salt of pentadecane-1,14-dicarboxylic acid was not successful and did not give products with a musk odor. *1-Methylcyclopentadecan-2-one* was prepd. by adding 4 g. cyclopentadecanone in 100 cc. abs. Et_2O to 4 g. finely divided $NaNH_2$ under PhH and cooled with ice, allowed to stand several hrs., then shaken 2 days at room temp. The flocculent Na deriv. of the ketone was decanted with the liquid from the solid residue of $NaNH_2$, which was washed with abs. Et_2O, the Et_2O suspension boiled 2 days with excess MeI, treated with H_2O and distd., b_{12} 171–3°, converted to *semicarbazone* (m. 149–50°) and then the ketone was regenerated from the latter with $H_2C_2O_4$; the odor is similar but slightly less than the unmethylated ketone, d_4^{16} 0.9213, n_D^{16} 1.4812, M_D 73.60. 1,3-Dimethylcyclopentadecan-2-one could not be prepd. by distn. of the Y salt of hexadecane-2,15-dicarboxylic acid and the product of distn. did not have a musk odor. Attempts to prep. 1-methylcyclopentadecan-3-one (*dl*-muscone) from the Th salt of 2-methyltetradecane-1,14-dicarboxylic acid were not successful but gave a product which is probably *Me ω-methyltetradecyl ketone*, forming a *semicarbazone*, m. 122°; similarly the Y salt yielded the same semicarbazone (m. 122°) and another *semicarbazone* which is probably the isomer, m. 83°; regeneration of the ketones from the mother liquors gave an oil with a strong musk odor indicating the presence of traces of *dl-muscone*. Distn. of the Y salt of 2,13-dimethyltetradecane-1,14-dicarboxylic acid did not yield 1,5-dimethylcyclopentadecan-3-one but gave a very small amt. of *Me 2,3-dimethyltetradecyl ketone* which was isolated as the *semicarbazone*, m. 78–9°; the distillate had a very slight musk odor. *1-Methylcyclopentadecan-4-one* was prepd. by heating the Th salt of 3-methyltetradecane-1,14-dicarboxylic acid (from 81 g. acid) which yielded 60 g. of distillate and when fractionated gave: (*a*) 4 g., b_{12} 45–90°; (*b*) 7.2 g., b_{12} 90–150°; (*c*) 10.7 g., $b_{0.5}$ 120–60°; (*d*) 3 g., $b_{0.5}$ 160–80°; (*e*) 4.2 g., $b_{0.5}$ 180–205°; (*f*) 8 g., $b_{0.5}$ 205–50°. Fraction *c* has a decided musk odor and yields the greatest quantity of *semicarbazone*, m. 161–2°, although the latter could be obtained from all fractions; the ketone regenerated from the semicarbazone, $b_{0.5}$ 125° and has an odor which cannot be distinguished from muscone. Distn. of the Th salt of 4-methyltetradecane-1,14-dicarboxylic acid gave *1-methylcyclopentadecan-5-one*, which was isolated as the *semicarbazone*, m. 164°. Methylation of dihydrocibetone gave *1-methylcycloheptadecan-2-one*, which $b_{0.5}$ 150° and has an odor that can hardly be distinguished from the unmethylated ketone; the *semicarbazone*, m. 142–3°. *1-Methylcyclopentadecan-1-ol*, m. 85–6°, was prepd. by the Grignard reaction from cyclopentadecanone (10 g.) and MeI (5 g.); at the same time a small amt. of compd., m. 162°, was obtained and this is probably a *dimol. cyclopentadecanone* ($C_{30}H_{56}O_2$) or a *pinacone* ($C_{30}H_{58}O_2$); when the methylcyclopentadecanol was dehydrated by heating several hrs. with 90% HCO_2H it gave almost quant. *1-methylcyclo-1-pentadecene*, b_{12} 152–3°, d_4^{22} 0.8697, n_D^{22} 1.4853, M_D 73.26; reduction with H and Pt black in EtOAc gave *methylcyclopentadecane*, b_{12} 147–8°, d_4^{21} 0.8576, n_D^{21} 1.4735, M_D 73.34. N. A. LANGE

The configuration of polymethylenedicarboxylic acids. III. *cis*-Cyclobutane-1,2-dicarboxylic acids. RICHARD KUHN AND ALBERT WASSERMANN. *Helv. Chim. Acta* 11, 600–9(1928); cf. *C. A.* 22, 1761, 1765.—Et 1,1,4,4-butanetetracarboxylate, b_2 170–80°, was prepd. from 168 g. $CH_2(CO_2Et)_2$ and 55 g. $C_2H_4Cl_2$ and converted almost quant. to *1,1,2,2-cyclobutanetetracarboxylic ester* (I) by the action of Br_2 on the Na salt in abs. Et_2O (cf. Perkin, *J. Chem. Soc.* 65, 572(1894); *Ber.* 26, 243(1893); Beilstein, 4th Ed., 9, 725). When 45.5 g. I was sapond. with 130 g. $Ba(OH)_2.8H_2O$ in 2700 cc. H_2O, then acidified with H_2SO_4, the crude acid heated 30 min. at 200°, the black sirupy residue dried over P_2O_5 and KOH, dissolved in 150 cc. abs. MeOH, treated with dry HCl for 3 hrs. at 0°, stoppered and allowed to stand 2.5 days at room temp., dild. with 700 cc. H_2O, extd. 5 times with 100-cc. portions of Et_2O, the Et_2O ext. washed with H_2O and then dil. Na_2CO_3, dried and the Et_2O removed, 6 g. of a mixt. of the Me esters of *cis-* and *trans-cyclobutanedicarboxylic acids* were obtained, b_{11} 102–8°; sapon. of these esters gave 4 g. of mixed acids, m. 90–100° (fraction A). The aq.-alc. soln. from the Et_2O extn. above was evapd. to dryness, the residue extd. in a Soxhlet with Et_2O and gave 5 g. of acids sol. in Et_2O, m. 80–110° (fraction B). Fractions A + B (9 g.) were fractionally recrystd. 7 times from 35% HCl; the less sol. acid, m. 130° (uncor.), is *trans-1,2-cyclobutanedicarboxylic acid* (II), which was dried at 120°, recrystd. from Et_2O-petr.

ether and then from pure PhH; yield, 3.1 g. The Ba salt of this *trans*-isomer is identical with the *cis*-salt described by Perkin. All of the HCl mother liquors from the previous fractionations were united and further fractionated by crystn.; when no more crystals sepd. on cooling to room temp., the soln. was cooled with ice and 1.7 g. *cis*-isomer (III) sepd.; crystals from PhH, m. 97–8°. Mol. wt. detns. on these acids are 15% higher than the calcd. values (cf. *C. A.* **22,** 5). When 0.15 g. III was heated in a sealed tube with 5 cc. 35% HCl for 4 hrs. at 190°, the HCl evapd. and the dry residue recrystd. from PhH, 0.9 g. of II was obtained; conversion of III into II was also obtained by heating 2.5 hrs. at 100° with Ac_2O but not by boiling AcCl. These results indicate that the similarly constituted pair of isomeric acids described by Perkin were both the same compd., *viz.*, the *trans*-isomer. The 1st and 2nd dissocn. consts. (log K_1 and log K_2) were as follows:

Compd.	In H_2O	t°	In 50% MeOH	t°
II	log K_1 3.79	19°	log K_1 4.80	18°
II	log K_2 5.61	20°	log K_2 6.95	19°
III	log K_1 3.90	19°	log K_1 4.94	18°
III	log K_2 5.89	18°	log K_2 7.21	18°

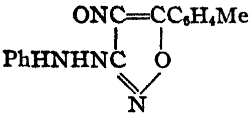
N. A. LANGE

The stereoisomers of quinitol (1,4-cyclohexanediol). L. PALFRAY AND L. ROTHSTEIN. *Compt. rend.* **186,** 872–4(1928).—Samples of quinitol prepd. by the method of Senderens and Aboulenc (*C. A.* **16,** 1087) at 130°, 160°, 180° and 200°, resp., were available. In order to study the effect of conditions of prepn. on compn. a practical method was developed for sepg. the isomers, based on the difference in soly. in Me_2CO. Crystals of *trans*-quinitol (I) are sepd. by means of a high-speed centrifuge; *cis*-quinitol (II) is obtained from the mother liquor by distn. of the solvent. 100 g. of quinitol, prepd. at 200°, gave 40 g. of I, m. 139°, 34 g. of II, m. 102° and 15 g. of a mixt. The m.-p. curve of mixts. of I and II goes through a min. at 45% of I. Quinitol is volatile in steam and sublimes readily at 150–200°. I crysts. in flattened needles. II solidifies after fusion in both cubic and uniaxial crystals, the latter becoming in a few min. triclinic needles similar to those obtained from solns. Phenylurethan of I, m. 262°, of II, m. 188°. Quinitol is unaltered by heating in a sealed tube 2 hrs. at 180°, but in contact with Hg 95% is changed to I, the stable isomer, in 20 min. at 150°. Hg also affects the transition of derivs. of I and II. In anhyd. Me_2CO the solubilities (presumably in parts per 100 parts of soln.—ABSTRACTOR) are, I at 14°, 1.86, at 16°, 1.91; II at 14°, 5.56, at 16°, 5.61. In Me_2CO contg. 5% H_2O the solubilities are, I at 12°, 2.55, at 17.5°, 2.76; II at 12°, 5.10, at 17.5°, 5.26. MARGARET W. MCPHERSON

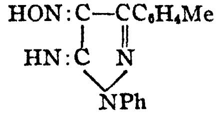
The fusion of cyclohexanol. N. N. NAGORNOV. *Ann. inst. anal. phys.-chim.* (*Leningrad*) **3,** 593–9; *Chem. Zentr.* **1927,** II, 2669.—Cyclohexanol, prepd. from PhOH by the method of Sabatier and Senderens, f. 23.72–23.40° and $b_{759.4}$ 160.4–0.6°. It exists in 2 allotropic modifications, the transformation point of which was 2.14°. The form stable at higher temps. dissolves considerable air, which is then evolved, with transformation into the other allotropic form. The dependence of the m. p. (t) on the pressure (P in megabars) between 1 and 127 megabars can be expressed as follows: $P = 441.80-51.5t + 1.394t^2$. The sp. vol. of the liquid is 1.0574 at 25° and is 1.0563 at 28.20°. The sp. vol. of solid cyclohexanol is 1.0304 at 25.10° and is 1.0284 at 28.20°. The heat of fusion at 23.7° is 2.71 cal. and at 28.20° is 5.44 cal. An extraordinarily small value of the heat of fusion which varies greatly with the pressure is obviously characteristic of hydroaromatic compds. (cf. Nagornov and Rotinjanz, *C. A.* **19,** 3266). C. C. DAVIS

Some heterocyclic derivatives of *p*-cymene. WALTER QVIST. Åbo Akad. (Finland). *Acta academiae Aboensis, mathematica et phys.* **4,** No. 3, 25 pp.; *Chem. Zentr.* **1927,** II, 1700–1.—A method for the *prepn. of di-p-toluylfuroxan* (I) is described and the action of amines and of hydrazines on this compd. was studied. The expts. show that the yields of acid hydrazides can be considerably increased if higher-boiling solvents are used in place of Et_2O in the prepns. *γ-Phenylhydrazino-β-nitroso-α-p-tolylisoxazole* (II), orange, prepd. by treatment of I with $PhHNNH_2$ in Et_2O, crystallizes from AcOH with 1 mol. of AcOH, dissolved in MeOH there seps. a cryst. *hydrate* contg. 2 mols. of H_2O, but no free isoxazole, as reported by Böeseken (cf. *Rec. trav. chim.* **16,** 297(1897)). The *isoxazole* is obtained only by keeping the hydrate over H_2SO_4. When the crystals contg. AcOH are dissolved in warm C_6H_6, a fairly stable cryst. *compd. with* C_6H_6 is obtained. When the C_6H_6 soln. is boiled, *1-phenyl-3-p-tolyl-4-isonitrosopyrazolone-5-imide* (III) or the *nitroso form* (IV) is formed, III probably being the red crystals and

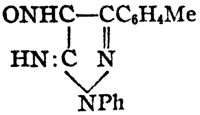
IV probably being in the green soln. with org. solvents and in the green fused product. **The compd. can also be conceived to be** ***1-phenyl-3-p-tolyl-4-nitroso-5-aminopyrazole*** **(V).**



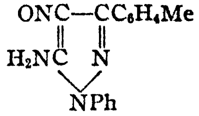
(II)



(III)



(IV)



(V)

Exptl.—**I** was prepd. by heating *p*-cymene (10 g.) with concd. H_2SO_4 (10 g.) on the water bath, cooling, adding concd. HNO_3 (90 cc.), after cessation of the reaction pouring into cold water and recrystg. from EtOH. It m. 125–6°. Heated 7 hrs. on the water bath with $PhNH_2$ in Et_2O there was formed, besides *p-toluanilide*, m. 147–8°, *γ-anilino-β-nitroso-α-p-tolylisoxazole*, a soln. of which in EtOH with Zn dust and AcOH at 50° is reduced to *γ-anilino-β-amino-α-p-tolylisoxazole*, m. 145–9°. Prolonged heating of I with *o*-toluidine in Et_2O forms *γ-o-toluidino-β-nitroso-α-p-tolylisoxazole*, $C_{17}H_{15}N_3O_2$, black-green, becomes yellowish at 110° and m. 130°, also turns yellowish on exposure to air without appreciable change of compn., so that possibly an isomeric azoxime deriv. is formed. I and *p*-anisidine in Et_2O heated 1 hr. yield after crystn. from EtOH *p-toluo-p-aniside*, $C_{15}H_{15}NO_2$, m. 168–9°. Treated with cold AcOH the residue of the Et_2O filtrate of this last compd. yields *γ-anisidino-β-nitroso-α-p-tolylisoxazole*, $C_{17}H_{15}N_3O_3$, sinters approx. 150°, m. 180° (decompn.). Boiled several hrs. with MeOH and recrystd. from C_6H_6 it forms *p-anisidino-p toluylazoxime*, $C_{17}H_{15}N_3O_3$, m. 189.5–90.5°. I boiled 6 hrs. with *p*-tolylhydrazine in xylene or C_6H_6, evapd. and recrystd from C_6H_6, yields *p-toluo-p-tolylhydrazide*, $MeC_6H_4CONHNHC_6H_4Me$ (VI), sinters 176°, m. 177–8°. With EtOH as the reaction medium, it is possible, after removal of VI, by treatment with warm AcOH to obtain *γ-p-tolylhydrazino-β-nitroso-α-p-tolylisoxazole*, $C_{17}H_{16}N_4O_2$.AcOH, orange, m. 87–8°. In a similar manner from *o*-tolylhydrazine in Et_2O are obtained *p-toluyl-o-tolylhydrazide*, $C_{15}H_{16}N_2O$, sinters 170°, m. 172–3°, and the *compd.* $C_{17}H_{16}N_4O_2$.AcOH, orange, decomps. 106°. I boiled 4.5 hrs. with *α*-naphthylhydrazine in Et_2O and the product recrystd. from C_6H_6, yields *p-toluyl-α-naphthylhydrazide*, $C_{18}H_{16}N_2O$, m. 219–22°. I boiled 4 hrs. with *p*-nitrophenylhydrazine in EtOH and the product recrystd. from AcMe, yields *p-nitrophenyl-p-toluylazoxime*, decomps. 255–7°. I boiled with $PhNHNH_2$ in xylene or C_6H_6 and the product recrystd. from C_6H_6, yields *p-toluophenylhydrazide*, $MeC_6H_4CONHNHPh$, m. 166–7.5°. With Et_2O in place of xylene the yield is smaller, and from the residue of the filtrate can be obtained, by treatment with AcOH, *γ-phenylhydrazino-β-nitroso-α-p-tolylisoxazole*, $C_{16}H_{14}N_4O_2$.AcOH, decomps. 86–7°. Recrystd. from MeOH, the *isoxazole*, $C_{16}H_{14}N_4O_2.2H_2O$, is obtained, which kept over H_2SO_4 is converted into free *γ-phenylhydrazino-β-nitroso-α-p-tolylisoxazole*, $C_{16}H_{14}N_4O_2$, decomps. 92.5–3.5°. In a C_6H_6 atm., this latter compd. absorbs C_6H_6, forming a *C_6H_6-addn. compd.*, decomps. 101–2°. The latter boiled in C_6H_6 forms, on recrystn. from C_6H_6, *1-phenyl-3-p-tolyl-4-isonitrosopyrazolone-5-imide*, $C_{16}H_{14}N_4O$, dark red, m. 233–4°, hydrolyzed to *1-phenyl-p-tolyl-4-isonitrosopyrazolone-5*, $C_{16}H_{13}N_3O_2$, red, decomps. 197–201°. C. C. DAVIS

Determination of the configuration of space-isomeric hydroaromatic compounds. K. v. AUWERS AND A. SCHMELZER. *Sitzb. Ges. Beförderung gesamten Naturwissenschaften Marburg* **62**, No. 4, 113–35; *Chem. Zentr.* **1927**, II, 1562–4.—Previous methods for solving the problem of the classification of space-isomeric cyclic compds. into different *cis-* and *trans-*series have in general proved to be unreliable. In detg. configurations Skita has therefore made use of 2 principles, (1) that on hydrogenation and reduction, *cis*-compds. are formed in acid soln. and *trans*-compds. in alk. soln., and (2) that *cis*-compds. have higher d and *n* values and lower [α] values than the corresponding *trans*-compds. The correctness of (1) was proved by Skita in only a few cases, and its general validity is to be accepted because in many individual cases it conforms with principle (2). The latter, suggested by v. A. (cf. *Ann.* **419**, 92), has not been definitely proved, and discrepant cases are known. As a result, the value of the Skita method has been placed in doubt, and a further investigation of its validity has become necessary. The present paper deals with this problem and utilizes methylcyclohexanols and methylcyclohexylamines and their urethan, *p*-nitrobenzoate, acyl and phenyl-

urea derivs. *1,2-Methylcyclohexanol.*—According to Skita (*Ann.* **431,** 4, 17) the long-known compd. is the *trans*-form (phenylurethan, m. 105°) and the newly prepd. isomer (phenylurethan, m. 95°) the *cis*-form. v. A. and S. have obtained the former by various methods. The spectrographic observations of Skita on this form agree well; nevertheless it is surprising that the $E\Sigma_D$ value is only a little different from that of the isomer. The observations of v. A. and S. vary, but show differences in the $E\Sigma_D$ values which are to be expected. A safe opinion whether the v. A. rule is correct in this case is not yet possible. *1,2-Methylcyclohexylamine.*—The compd. obtained in alk. soln. from 1,2-methylcyclohexanone oxime is, according to the Skita rule, the *trans*-form, since on conversion to the alc. no unsatd. hydrocarbon is formed. A higher m. p. of its phenylurea than reported by earlier investigators (cf. Skita, *Ber.* **56,** 1015) was found. The phys. consts. deviate from the Skita values, but agree with those of Gutt (cf. *Ber.* **40,** 2065(1907)). *1,3-Methylcyclohexanol.*—The data in the literature are discordant. Its identification is difficult, for its esters remain in an oily form, and the m. ps. of their phenylurethans differ but little, according to Skita 91° for the *cis*- and 96–7° for the *trans*-form. v. A. and S. obtained a compd. having the m. p. of the *cis*-form, though according to its mode of prepn. it should have been the *trans*-form. With respect to the spectrographic data Skita had already shown that the rule is not valid in every respect, since the n value of the *cis*-form is smaller than that of the *trans*-form. In far greater opposition to the rule are the older observations of Knoevenagel (*Ann.* **297,** 117(1897)), according to which the relation between the consts. is exactly reversed. The d. data of Skita also controvert the rule. The same anomalies appear especially in the *m* series. *1,3-Methylcyclohexylamine.*—This was prepd. in alk. soln. The m. ps. of its derivs. differed from those recorded by Skita for the *trans*-forms. Perhaps some *cis*-compds. were formed in spite of the alk. media. The spectrochem. observations of Skita again controvert the rule in this case, but it is questionable whether these data are wholly reliable, for the values found by v. A. and S. agree well with those of Gutt. Whether here a true deviation from the rule exists is still uncertain. *1,4-Methylcyclohexanol.*—The spectrochem. observations of the *trans*-form agree well, but are less concordant for the *cis*-form, so that the mutual relation is still uncertain. *1,4-Methylcyclohexylamine.*—Data in the literature on the m. p. of the phenylurea are very discordant. With respect to the spectrochem. data on the *trans*-form there is better agreement in the data of Gutt than in those of Skita. As yet no final conclusions can be drawn from these investigations. It is believed by v. A. and S. that the mode of experimentation of Skita leads to the formation of both space-isomers as is the case in all such reductions. A reliable decision is possible, however, only when from homogeneous derivs. the carbinols and amines are regenerated. Far more difficult is the detn. of the configuration of each individual compd. The older rule that *cis*-forms melt at the lower temps. and are the more volatile has, on account of numerous exceptions, only a probability value. The belief that more reliable conclusions can be drawn from closing and opening of rings is also now discredited, as evidenced particularly by the expts of Böeseken. An explanation of these phenomena is probably to be sought in the fact that atoms in rings of more than 5 members lie in different planes (cf Hückel, *Ann.* **451,** 109). Moreover Ott and Schröter (*Ber.* **60,** 624) have shown that the formation of *cis*- and *trans*-forms is associated with energy rather than with spatial relations. The surest guide to the detn. of configuration remains a study of the asym. C atom. If a compd. theoretically can exist in a *dl*- and in a *meso*-form, then *cis*- and *trans*-modifications are certain, provided that the optical resolution of 1 isomer is accomplished. The carbinols and amines would have to be transformed first into the appropriate compds., because of their unsym. structure, which precludes *meso*-forms. The Walden transformation is also to be considered. Thus Sabatier obtained from 1,2-methylcyclohexanol (*trans*) various 1,2-methylchlorocyclohexanes depending upon whether PCl_5 (Gutt) or HCl (Zelinskii, *Ber.* **41,** 2680 (1908)) was used. The product from PCl_5 yielded with Mg and CO_2 solid, the other yielded liquid hexahydro-*o*-toluic acid. If the solid acid is considered to be the *trans*-form, as usual, then according to the transformation with HCl a Walden conversion should take place. In this case the consts. of the chloride would not conform to the v. A. rule; otherwise the configuration of the acids would have to be changed, or Walden conversion assumed for the transformation of the chlorides into the acid. The following exptl. data show the consts. obtained by v. A. and S. for the compds.: *Cyclohexanol,* prepd. from cyclohexanone with Na in Et_2O + water, b. 157–9°, d_4^{20} 0.948, n_{He}^{20} 1.4629, $E\Sigma_D$ −0.17, $E\Sigma_{\beta-\alpha}$ 2%. *Ac deriv.,* prepd. by boiling Ac_2O, b. 173.5–174.5°, d_4^{20} 0.974, n_{He}^{20} 1.4411, $E\Sigma_D$ −0.05, $E\Sigma_{\beta-\alpha}$ −3%. *m-Nitrobenzoyl deriv.*

$C_{13}H_{15}O_4N$, oil. *p-Nitrobenzoyl deriv.*, $C_{13}H_{15}O_4N$, m. 50.5–51.5°. *Phenylurethan*, m. 81.5°. *Cyclohexylamine*, prepd. from cyclohexanone oxime with Na in boiling EtOH, with steam-distn., concn. with HCl and decompn. with alkali, d_4^{20} 0.873, n_{He}^{20} 1.4605, $E\Sigma_D$ —0.01, $E\Sigma_{\beta-\alpha}$ —2%. *1,2-Methylcyclohexanol* was prepd. in 3 ways: (1) from *o*-cresol by the Sabatier method; (2) from the ketone with Na and boiling EtOH, and (3) from 1,2-methylcyclohexylamine-HCl in warm water with $NaNO_2$ + AcOH, under which conditions it b. 167.6°, 167°, 168°, b_{18} 71–2°, d_4^{20} 0.928, 0.926, 0.927, n_{He}^{20} 1.4634, 1.4613, 1.4608, $E\Sigma_D$ 0.05, —0.01, —0.08. *Ac deriv.*, b. 183–4°, d_4^{20} 0.949, n_{He}^{20} 1.4383, $E\Sigma_D$ −0.01, $E\Sigma_{\beta-\alpha}$ —2%. *m-Nitrobenzoyl deriv.*, $C_{14}H_{17}O_4N$, oil. *p-Nitrobenzoyl deriv.*, m. 64.5–65.5°. *Acid phthalate*, $C_{15}H_{18}O_4$, prepd. in C_5H_5N with pptn. by Na_2CO_3, m. 122–3°. *Phenylurethan*, m. 105–6°. *α-Naphthylurethan*, $C_{18}H_{21}O_2N$, m. 156–7°. *1,2-Methylchlorocyclohexane*, prepd. from the carbinol with 2 vols. of fuming HCl for 4.5 hrs. at 120–30°, b. 152–4°, d_4^{20} 0.967, n_{He}^{20} 1.4586, $E\Sigma_D$ 0.18, $E\Sigma_{D\beta-\alpha}$ 2%. *1,2-Methylcyclohexylamine*, from 1,2-methylcyclohexanone oxime, b. 145–6° (in H current), d_4^{20} 0.854, n_{He}^{20} 1.4550, $E\Sigma_D$ 0.18, $E\Sigma_{D\beta-\alpha}$ 2%. *Picrate*, yellow, m. 178–9°. *Bz deriv.*, m. 149–50°. *Phenylurea*, $C_{14}H_{20}ON_2$, m. 156–8°. *1-Methylurea*, $C_{18}H_{34}ON_2$, crystd. from abs. EtOH, m. 214–5°. *1,3-Methylcyclohexanol*, prepd. in 3 ways: (1) from *m*-cresol by the Sabatier method, b_{17} 80–1°, d_4^{20} 0.918, n_{He}^{20} 1.4591, $E\Sigma_D$ 0.12; (2) the *trans*-form of Skita (phenylurethan m. 93°), b. 171.5–172.5°, d_4^{20} 0.919, n_{He}^{20} 1.4589 and (3) the *cis*-form of Skita, b. 174.6–175.0° (cor.), d_4^{20} 0.923, n_{He}^{20} 1.4565. *m-* and *p-Nitrobenzoyl derivs.*, $C_{14}H_{17}O_4N$, oils. *Phenylurethan*, $C_{14}H_{19}O_2N$, m. 90.5–91.5°. *α-Naphthylurethan*, $C_{18}H_{21}O_2N$, m. 128.5–9.5°. *1,3-Methylcyclohexylamine*, b. 144–5°, d_4^{20} 0.848, n_{He}^{20} 1.4524, $E\Sigma_D$ 0.23, $E\Sigma_{\beta-\alpha}$ 3%. *Picrate*, oil. *Bz deriv.*, $C_{14}H_{19}ON$, prepd. with ice-cold 2 *N* NaOH, m. 108°. *Phenylurea*, $C_{14}H_{20}N_2$, m. 162.5–165°. *1,4-Methylcyclohexanol*, prepd. in 3 ways: (1) by the method of Skita which gives the *trans*-form, b. 171.3–172° (cor.), d_4^{20} 0.920, n_4^{20} 0.920, n_{He}^{20} 1.4595, $E\Sigma_D$ 0.07; (2) from *p*-cresol by the method of Sabatier, b. 172.5–172.8°, d_4^{20} 0.917, n_{He}^{20} 1.4583, $E\Sigma_D$ 0.10 and (3) by the method of Skita which gives the *cis*-form, b. 173–173.8° (cor.), d_4^{20} 0.9185, n_{He}^{20} 1.4952, $E\Sigma_D$ 0.15. *p-Nitrobenzoyl deriv.*, $C_{14}H_{17}O_4N$, m. 62–3°. *Phenylurethan*, m. 123.5–124.5°. *1,4-Methylcyclohexylamine*, m. 147–8° (in a H current), d_4^{20} 0.846, n_{He}^{20} 1.4514, $E\Sigma_D$ 0.23, $E\Sigma_{\beta-\alpha}$ 3%. *Picrate*, oil. *Bz deriv.*, m. 177–8°. *Phenylurea*, $C_{14}H_{20}ON_2$, m. 210–11°. C. C. Davis

Laws of aromatic substitution. IX. Bernhard Flürscheim and Eric Leighton. *J. Chem. Soc.* 1928, 2230–42; cf. *C. A.* **22**, 3403.—The following figures give the av. mol. % of *m*-substituent formed on nitrating and the ratio of $m/(o + p)$: PhCN, 88.25, 751; $PhCH_2CN$, 12.70, 14; $PhCH(CO_2Et)CN$, 37.20, 59.2; $PhCH(CN)_2$, 67.90, 211.8; $PhC(CO_2Et)_2CN$, 69.55, 228.6; $PhC(CO_2Et)(CN)_2$, 87.5, 698.4; PhCHClCN, 50.05, 100.20; PhCH(OH)CN, 43.55, 77.25; $PhCH:NC_6H_4NO_2$-*m*, 87.05, 672.2; PhCHO, 78.65, 368.4. *Et phenylcyanomalonate*, b_1 140–1°, from $PhCH_2CO_2Et$, Na and $ClCO_2Et$. *Et phenyldicyanoacetate*, m. 60°, from $PhCH(CN)_2$, Na and $ClCO_2Et$. Full details are given of the nitration expts. The relative effects of Cl, CO_2Et and CN are discussed. C. J. West

Steric hindrance. Walter Hückel. Univ. Freiburg i Br. *Ber.* **61B**, 1517–24 (1928).—To answer some of the objections which were raised against the Meyer theory of steric hindrance, the assumption of "chem." influences of the adjacent substituents on the reactive group, in addn. to "spatial" factors, was invoked. In the interpretation of the phenomena grouped under "steric hindrance" there was thus introduced an arbitrary concept which must persist as long as it is not possible to sep. the "chem." and "mech." constitutional influences and to represent them by measurable magnitudes. The study of sterically hindered reactions would seem to be a part of the problem of the relation between reaction velocities and constitution. But the reaction velocity consts. amenable to direct measurement are themselves functions of several variables, each dependent in its own peculiar way on the constitution. By making certain assumptions, however, the reaction velocity consts. can be essentially represented as the function of 2 variables, $k = \alpha . e^{-q/RT}$, where q is the activating energy (the energy which must be supplied to the reacting mols. to bring them to the state where they can react) and α represents the frequency of successful approaches to each other of the reacting mols. (cf. Trautz, *C. A.* **13**, 3053, and others); H. calls α the "action const." q can be calcd. from the temp. coeffs. of k, and α by substituting the calcd. value of q in the above equation for k measured at any desired temp. A decrease in α with change in structure might then be pictured as a narrowing or a de-

crease in the no. of the paths leading to the reacting groups and an increase in q as a change from a level or gently rising road to a steep mountain road. Calcn. of q and α from Vavon's measurements of the esterification velocities at different temps. of the *cis*- and *trans*-forms of various substituted cyclohexanols (V. and Anziani, *C. A.* **22,** 1334, and earlier papers) shows that considerable variations in reaction velocity may rest on great variations in q as well as of α; whether or not this is a case of "steric" hindrance cannot be definitely detd. A similar calcn. from Olsson's measurements of the sapon. velocities of various esters shows that with esters of primary alcs. the values of q and α are approx. equal while for the 1 tertiary alc. studied q is about 1000 cal. smaller and α about 10 times smaller, both factors tending to decrease the velocity const. of sapon., which is about 10^2 smaller than that of the primary alc. esters; with the esters of secondary alcs. the values of q and α show a drift with the temp.; whether this is real and the formula therefore does not hold strictly or is due to errors in measurement or impurities in the substances used cannot for the present be detd. In studies on the influence of substituents on velocity consts. differences in the velocity consts. have often been tacitly aligned with corresponding differences of the activating energy (the greater the const. the less the activating energy), deviations from the expected parallelism being ascribed to "steric" factors. But such a relationship cannot be expressed quant. for the difference in activating energy depends on the nature of the substitution reaction (*e. g.*, in the bromination of PhMe $q_o - q_p = 658$, in its nitration 135). Thus Olivier (O. and Berger, *C. A.* **21,** 3356, and earlier papers) concludes from the sapon. velocities of the halogenated benzyl chlorides that there is no steric factor because the ratio k_o/k_p is generally about the same whereas, he thinks, according to the theory of steric hindrance it should decrease in the series Cl ⟶ Br ⟶ I with the size of these atoms, but his data show that the magnitude of the action const. changes in a varying, often quite striking manner according as the substituents are in the *o*-, *m*- or *p*-position. Taking as an example of the application of the above views to equil consts. the relation between constitution and the dissocn. consts. of org. acids, which depend on the ratio of the frequency of the dissocn. process k_d to that of the association process k_a, it is quite conceivable that the increase in the dissocn. const. by an *o*-substituent may be due not only to an increase in k_d (chiefly represented by the activating energy necessary to split off the H ion) but to a decrease in k_a, as the result either of a decrease in the action const. or an increase of the activating energy, without any material increase in k_d. C. A. R.

Steric hindrance in the behavior of phenyl alkyl ethers and derivatives. L. CHAS. RAIFORD AND D. M. BIROSEL. State U. of Iowa. *Proc. Iowa Acad. Sci.* **34,** 222–3 (1927).—It is known that Ph alkyl ethers substitute in the Ph radical less easily than phenol; nevertheless, PhOEt will give a tribromophenyl compd. When the allyl deriv. is used, both Ph and allyl radicals may be involved in the change. Expts. in progress show that rearrangement of the allyl ether by heat, according to Claisen's method, may cause a loss of Br. W. G. GAESSLER

Effect of substituents in the formation and reactions of certain ethers. L. CHAS. RAIFORD AND GARRETT THIESSEN. State U. of Iowa. *Proc. Iowa Acad. Sci.* **34,** 220–1(1927).—The structures of several derivs. prepd. to show that the presence of a nitro radical in Ph_2O interfers with the entrance of Br to a much greater degree than could have been predicted on the ground of steric hindrance, have been detd. in several cases and a no. of other new halogenated derivs. have been prepd. These expts. have been conducted in the presence of aq. alkali, a method which was in part standardized and designated in previous work (*C. A.* **20,** 3694) as the "wet method." In the present work this process has been shown to be capable of 2 modifications, each with somewhat sp. applications which can, in general, be predicted. A 2nd point of interest in this work is the structure of the tetra-Br deriv. of Ph_2O obtained some years ago by Cook (*C. A.* **4,** 3206) by direct bromination. A no. of derivs. of this product have been obtained, but there is still some doubt as to the exact structure of the compd. Negative results are due in part to the stability of Ph_2O derivs., which makes it difficult to "split" the compds. in such a way as to recognize the character of the radicals present. W. G. GAESSLER

***o*-Effect and reactivity. I. Magnitude and cause of the *o*-effect in the hydrolysis of aromatic esters.** KARL KINDLER. Univ. Hamburg. *Ann.* **464,** 278–92(1928).—The total effect of a radical R in the *o*-position with respect to CO_2Et in a C_6H_6 nucleus is the result of (1) the influence of R on the strength of attachment of the whole aryl grouping to the CO_2Et group, shown in previous papers to det. the rate of hydrolysis of the ester, and (2) the direct influence of R as a center of unsatn. on the CO group. It is possible to det. the 2nd or "*ortho*" effect as follows: The *o*-effect is negligible in

esters of the type $RC_6H_4CH{:}CHCO_2Et$; the strengths of attachment (*a*) of Ph, (*b*) of RC_6H_4, (*a'*) of styryl and (*b'*) of $RC_6H_4CH{:}CH$ are found to be connected by the equation $\sqrt{a}:\sqrt{b} = a':b'$. By detg. the rates of hydrolysis of a series of *o*-substituted benzoic and cinnamic esters, it is thus possible to calc. (*b*) and so det. the direct *o*-effect. For R = F, Cl, Br, I and NO_2, the relative strengths of attachment of RC_6H_4 to the CO_2Et group are given by the figures 18.2, 25.2, 10.6, 15.8 and 1.91, resp., the relative *o*-effects of R being given by the figures 1, 2, 5, 7.5 and 11, resp. These last figures assume more importance when expressed on the basis of Cl = 35.5, when they become 17.8, 35.5, 88.8 and 133 for the 4 halogens. The velocity coeffs. for the alk. hydrolysis are given for *o*-$FC_6H_4CO_2Et$, 0.272; *p*-deriv., 0.0939; *o*-$ClC_6H_4CO_2Et$, 0.0937; *o*-$BrC_6H_4CO_2Et$, 0.0925; *o*-$IC_6H_4CO_2Et$, 0.0409; *o*-$O_2NC_6H_4CO_2Et$, 0.280. *o-Fluorocinnamic acid*, m. 175° (cor.); *Et ester*, b_{11} 140–1°, *k* 0.248; *Et p-fluorocinnamate*, b_{11} 135–40°, m. 30–2°, *k* 0.145; *o*-Br deriv., *k* 0.325; *p*-Br deriv., 0.238; *o*-I deriv., 0.267; *p*-I deriv., 0.239; *m*-NH_2 deriv., 0.0661. The cause of the *o*-effect is discussed. It is not steric in origin and is attributed to the unsatd. nature of the group in question. The strongly unsatd. NO_2 group has a particularly large *o*-effect. C. J. West

The reactions of Friedel and Crafts, Fries and Gattermann. K. v. Auwers and W. Mauss. Chem. Inst., Marburg. *Ber.* **61B**, 1495–507(1928).—Meisenheimer and Hanssen (H., *Diss. Tübingen* 1926) found that 2,4-$Me_2C_6H_3OMe$ (I) with BzCl and $AlCl_3$ gives, besides the *o*-hydroxy ketone, a *m*-hydroxy ketone as chief product, the orienting influence of the two Me groups therefore being stronger than that of the MeO group. If this hitherto unknown course of a Friedel-Crafts reaction should occur regularly with phenol ethers of a definite structure it might make possible the prepn. of certain *m*-hydroxy ketones which can hardly be made by other methods. In agreement with Meisenheimer, certain expts. along this line have therefore been made. Replacing the BzCl in Hanssen's expt. with AcCl, v. A. and M. obtained, in addn. to the known 2,4,6-$AcMe_2C_6H_2OH$, m. 53–4°, an isomer (II), m. 131°, non-volatile with steam, and its *Me ether*, m. 51°, volatile with steam and easily hydrolyzed to II. II regenerated 2,4-$Me_2C_6H_3OH$ (III) when boiled with H_3PO_4 and could therefore be only 1 of the 2 possible *m*-Ac derivs. Its ability to form an oxime showed that it is *2,4-dimethyl-5-acetophenol*. Similar results were obtained with $ClCH_2COCl$ instead of AcCl and with 2,4-$EtMeC_6H_3OH$ (IV) instead of I. It may therefore be concluded that the ethers of all dialkylphenols analogous to III give in the F.-C. reaction with acid chlorides more or less of the *m*- along with *o*-hydroxy ketone. Another group of phenols which can give a *m*-deriv. is that of the sym. trisubstituted compds. Under the ordinary conditions the reaction proceeds only with difficulty and incompletely, most of the original ether being recovered unchanged, but the part that does react is converted almost exclusively into a *m*-hydroxy ketone. Thus, it had already been shown (*C. A.* 22, 3646) that 2,4,6-$Me_2EtC_6H_2OMe$ gives 2,4,6,3-Me_2EtAcC_6HOH, and mesitol (V) has now been found to yield *m-acetomesitol* (VI), m. 81–2°, whose structure is proven by its regeneration of V with boiling H_3PO_4. The course of the reaction may be more complicated with those phenol ethers which have more loosely bound substituents (*e. g.*, Et) on the nucleus. As already shown, 2,4,5-$Et_2MeC_6H_2OMe$ with AcCl and $AlCl_3$ gives both 2,4,5,6-Et_2MeAcC_6HOH and 2,4,5-$AcEtMeC_6H_2OH$, the 2-Et group in part of the mol. being split off. Similarly 2,5,4-$Et_2MeC_6H_2OMe$ (VII) with 1.5 mols. each of AcCl and $AlCl_3$ in CS_2 gives an alkali-sol mixt. consisting chiefly of a yellow oil (VIII), b_{15} 144–7°, with a very small quantity of a reddish yellow oil (IX), b_{15} 164–72°, and an alkali-insol. part consisting mostly of unchanged VII with a little yellowish oil, b_{16} 148–62°, which was not further studied. That VIII is an *o*-hydroxy ketone was shown by the deep blue color which it gives with $FeCl_3$ and since on reduction by the Clemmensen method it gives *4-methyl-2,5-diethylphenol* (X), m. 54°, it must be *4-methyl-5-ethyl-2-acetophenol*. **IX** also gives a deep blue color with $FeCl_3$ and is probably 2,5,4,6(?)-Et_2MeAcC_6HOH. Under certain conditions a *m*-Et group may be split off. *2,4-Dimethyl-5-ethylphenol Me ether* (XI), obtained by reduction of the Me ether of II by the Clemmensen method, with 1.5 mols. AcCl and 2 mols. $AlCl_3$ gave considerable II and an oil (XII), b_{11} 150–60° (about 2 g. from 10.5 g. XI), sol. in alkalies with yellow color and giving a blue color with $FeCl_3$. Its oxime with boiling HCl gave a base and the XII may therefore be assigned the structure 2,4,5,6-Me_2EtAcC_6HOH. A 3rd product, m. 120–5°, was obtained in too small quantity for identification. In the above 3 cases the Et group is split off although there is an unoccupied *o*-position; the last example shows distinctly that alkyls tend to direct an entering acyl group more to the *p*- than to the *o*-position to themselves. All the above results show, furthermore, that, like the Fries shiftings, the F.-C. reaction with polyalkylated phenol ethers may proceed in quite different

ways and therefore the structure of the resulting products must be detd. in each individual case. When Hanssen heated the benzoate of III with 1.5 parts $AlCl_3$ 4 hrs. at 130–40°, he recovered 70% of the material unchanged and 17% changed into a mixt. of 2,4,6-, 2,4,5- and 2,5,4-$Me_2BzC_6H_2OH$ but a repetition of his work gave quite different results. The normal product of shifting, the 2,4,6-compd. (**XIII**), was obtained in 50% yield and in pure form, m. 40–1° (H.'s impure prepn. remained oily); the oxime, like H.'s, m. 153–4°. Of the 2,4,5-compd., m. 140–1°, only a small quantity (about 4%) could be isolated. No unchanged benzoate or 2,5,4-$Me_2BzC_6H_2OH$ was obtained. The difference in the results is easily explained. The formation in H.'s expt. of the 2,5,4-compd. was undoubtedly due to the presence of some *p*-xylenol in his III, and the fact that in spite of the high temp. he recovered 70% of his material unchanged indicates that his $AlCl_3$ was not fresh and was therefore no longer able to effect a true Fries shifting but in part did not act at all and in part exerted only a hydrolytic action, the resulting BzCl then effecting a F.-C. synthesis in the manner characteristic of phenols of the type of III. The formation of the small quantity of the 2,4,5-compd. in the v. A. and M. expt. may also have been due to a preliminary hydrolysis by the $AlCl_3$, the extent of which depends on the quality of the $AlCl_3$ and perhaps on the firmness with which the acid radical is held. The important point is that whereas the F.-C. reaction may with phenols of a definite structure give *m*-derivs. as the chief products, this is not the case in the Fries shifting, *i. e.*, it makes a difference whether the acid residue is introduced into the phenol from without or is already present in the phenol. v. A. and M. conclude that the Fries shifting occurs within a single mol. and is therefore fundamentally different from the F.-C. reaction. It had already been shown that a Me group forced to migrate by an acid residue can itself displace an Et group. To det. whether this occurs regularly, *2,5-dimethyl-4-ethylphenyl acetate* (**XIV**) was heated with $AlCl_3$; the only rearrangement product was the same 2,4,3,6-Me_2EtAcC_6HOH as was previously obtained from 2,6,4-$Me_2EtC_6H_2OAc$, but when *4-methyl-2,5-diethylphenyl acetate* (**XV**) was treated in the same way, the *m*-Et group was forced to migrate by the Ac residue but was unable to displace the *p*-Me group, going instead to the 5-position; the product was 4,2,3,6-$MeEt_2AcC_6HOH$; at the same time was formed a small quantity of another substance (**XVI**) which in all probability was the normal product of shifting, 4,2,5,6-$MeEt_2AcC_6HOH$, for its oxime on boiling with HCl underwent the Beckmann rearrangement completely or in part, indicating the presence of an alkyl next to the Ac group. In a repetition of the earlier expts with 2,5-$Me_2C_6H_3OH$, the normal rearrangement product, 2,5,6-$Me_2AcC_6H_2OH$ (**XVII**), which before had been sought in vain, was again not obtained in pure state but there was formed a substance whose oxime gave an aminophenol with boiling HCl Since the F.-C. reaction gives *m*-hydroxy ketones in certain cases, it became necessary to det. whether the Gattermann aldehyde synthesis may also proceed in this way under certain conditions. A series of phenols (including **III**) gave, along with the *o*- or *p*-hydroxy aldehydes, either no other compd. at all or only very small quantities. Mesitol Me ether, however, in a 1st expt. gave an alkali-insol. aldehyde (**XVIII**) sapond. by $AlCl_3$ to a *trimethylhydroxybenzaldehyde* (**XIX**), m. 106–9°, which is certainly not an *o*-deriv. and is probably 2,4,6,3-$Me_3(HO)C_6HCHO$. In a 2nd expt. was formed directly a very small quantity of a *dimethylhydroxybenzaldehyde* (**XX**), m. 106–7° (*oxime*, m. 164.5–5°), which proved to be different from the known, 3,5,4-$Me_2(HO)C_6H_2CHO$; because of the poor yields and the high cost of the material, it was not further investigated. A 3rd expt. gave the same results as the 1st. As the yield of **XIX** was small and reduction by the Clemmensen method also gave a small yield of the corresponding Me_4C_6HOH, the latter could not be completely purified; it m. 75–6.5° while the m. p. of 2,3,4,6-Me_4C_6HOH is given in the literature as 80–1°. The above structure is therefore assigned to **XIX** only with some reserve. 2,3-$Me_2C_6H_3OH$, as expected, gave 2,3,4-$Me_2(HO)C_6H_2CHO$ (**XXI**) almost exclusively, but the 2,3,4-$Me_3C_6H_2CHO$, obtained by reduction of **XXI**, yielded only a small quantity of the normal product, *3,4,5-trimethyl-2-hydroxybenzaldehyde* (**XXII**), the chief product being **XXI**. This shows how strong is the tendency to the formation of *p*-derivs. in the Gatterman synthesis and is worthy of note in that it is not a loosely held Et group but a Me group which is driven out. The above expts. give little indication of any tendency to the formation of *m*-derivs. in the G. synthesis but show that the displacement of alkyls occurs as readily as in the Fries shifting. *Me ether* of **II**, b_{13} 140–2°. Free **II** gives a faint greenish color with $FeCl_3$ and dissolves in alkalies with yellowish color; *oxime*, m. 42–6°. *m-Chloroaceto-asym-m-xylenol*, m. 107–7.5°, somewhat volatile with steam, gives no color with $FeCl_3$. *2-Ethyl-4-methylphenyl Me ether*, b. 206–8°, gives by the F.-C. reaction *2-ethyl-4-methyl-5-acetophenyl Me ether*, faintly yellow,

b_{16} 148–50°, the yellow 2,4,6-$EtMeAcC_6H_2OH$, and *2-ethyl-4-methyl-5-acetophenol*, m. 120–1°, which gives a faint green color with $FeCl_3$ and is readily reduced to *4-methyl-2,5-diethylphenol*, m. 54–54.5°, b. 248–50°; whose *Me ether* b. 234–6°. *2,5-Dimethyl-4-ethylphenol*, m. 39–40°, gives only a very faint green color with $FeCl_3$; *acetate* (XIV), b. 248–50°. XV, b. 260–2°. XXII, m. 36–7°, sol. in dil. NaOH with bright yellow color, gives a deep greenish blue color with $FeCl_3$. C. A. R.

Mechanism of the Fries rearrangement. K. v. Auwers and W. Mauss. Univ. of Marburg. *Ann.* **464**, 293–311(1928); cf. *C. A.* **22**, 1762, 3646.—The claims of Rosenmund and Schnurr (*C. A.* **22**, 1579) in connection with the general improvement of methods of effecting the Fries rearrangement is criticized, for although R. and S. have considerably improved those methods, some phenol esters, *e. g.*, the Ac and Bz deriv. of 2-hydroxymesitylene, do not undergo the change under the conditions laid down by R. and S. Moreover, phenyl benzoates and chloroacetates require more drastic treatment than do the corresponding acetates. Thus, $ClCH_2CO_2Ph$ and $ClCH_2CO_2C_6H_4Me$ (*m*) do not undergo the Fries change in 1 day in cold $PhNO_2$ and $AlCl_3$, whereas *m*-$MeC_6H_4CO_2Me$ and 2-*m*-xylyl acetate under similar conditions afford good yields of ketones. 4- and 5-Xylyl acetates, the acetate and chloroacetate of 2,6,4-$Me_2EtC_6H_2OH$ and the *chloroacetate*, b_{12} 138°, of 3-chloro-*o*-cresol, are to a slight extent hydrolyzed but are otherwise unaffected under these conditions. *2,4,6-Trichlorophenyl acetate*, m. 49–51°, is unaffected by $AlCl_3$ in 0.25 hr. at 150°, while after 4 hrs. at 130–40° in presence of excess of chloride, tar, some $Cl_3C_6H_2OH$ and a trace of an *o*-hydroxy ketone (?) are found. When heated with $AlCl_3$ for 1 hr. at 100–40°, 2,6-$ClMeC_6H_3O_2CCH_2Cl$ gives, as main product, *3-chloro-4-hydroxy-5-methylphenacyl chloride*, m. 98.5–9.5°; whether or not any *o*-displacement occurs is uncertain. R. and S.'s conclusion that the Fries rearrangement is bimol. in type, *i. e.*, is a reaction of the Friedel-Crafts type between 2 mols. of a phenol ester, is open to criticism, if for no other reason than that while Fries changes lead to *o*- as well as to *p*-compds., Friedel-Crafts reactions give exclusively the latter. Other evidence shows the untenability of R.'s view. Meissenheimer and Hanssen (*Diss. Tübingen* 1926) have shown that BzCl and 4-*m*-xylyl Me ether under Friedel-Crafts conditions give mainly 2,4,5-$Me_2(HO)C_6H_2Bz$, *i. e.*, the Bz radical goes *m* to the MeO group. Were R.'s contention correct, 4-*m*-xylyl acetate, under Fries conditions, should give 2,4,5-$Me_2(HO)C_6H_2Ac$, while in practice it gives, as the only recognizable product, 3,5,2-$Me_2(HO)C_6H_2Ac$. When a mixt. of the acetate and Me ether of 4-*m*-xylenol is warmed with $AlCl_3$ in $PhNO_2$, the ether is unaffected and the acetate gives 3,5,2-$Me_2(HO)C_6H_2Ac$, *i. e.*, no acetate reacts in the sense to be anticipated from R.'s theory. The main support for the latter theory is the formation from a mixt. of 2,4-$ClMeC_6H_3OAc$ and *p*-MeC_6H_4OBz (Fries conditions) of 3,5,2-$ClMe(HO)C_6H_2Bz$ and 5,2-$Me(HO)C_6H_3Ac$, in addn. to the normal products, *viz.*, 3,5,2-$ClMe(HO)C_6H_2Ac$ and 5,2-$Me(HO)C_6H_3Bz$. A. and M. have obtained the same results but have also isolated some 2,4-$ClMeC_6H_3OBz$ It is shown that exchange of acyl groups frequently occurs when phenol esters of different acids are together submitted to Fries conditions, although this does not necessarily take place with every pair. Thus, a mixt. of PhOAc and *p*-$MeC_6H_4CO_2CH_2Cl$ gives only 2- and 4-HOC_6H_4Ac and 5,2-$Me(HO)C_6H_3COCH_2Cl$ and, if mild conditions are employed, even the latter is not formed. Similarly, a mixt. of *p*-MeC_6H_4Ac and 3,4-$ClMeC_6H_3OBz$ gives only traces of hydroxy ketones derived from intermediate reciprocal exchange of acyl radicals. That is, the course of all such reactions is detd. by the nature of the substance concerned (the Bz and $ClCH_2CO$ groups are more firmly attached to O than is the Ac group). A mixt. of 2,6-$Me_2C_6H_3OAc$ and *p*-MeC_6H_4OBz gives xylenol and cresol, together with 5,2-$Me(HO)C_6H_3Ac$ and 5,2-$Me(HO)C_6H_3Bz$. A mixt. of 2,4,6-$Me_3C_6H_2OAc$ and *p*-$MeC_6H_4CO_2CH_2Cl$ gives cresol, 2-hydroxymesitylene, the acetate of the latter and 3,4,5,2-$Me_3(HO)C_6HAc$. *2,6-Dimethyl-4-ethylphenyl chloroacetate*, b_{12} 156°, m. 77–8°, gives a small quantity of 3,5,4-$Me_2(HO)C_6H_2COCH_2Cl$. A mixt. of the same chloroacetate with *p*-MeC_6H_4OAc ($AlCl_3$; 150°) gives 5,2-$Me(HO)C_6H_3Ac$ and unchanged chloroacetate, together with a trace of an *o*-hydroxyphenacyl chloride (?). To det. whether in fact an acyl group attached to the O atom of 1 phenol can enter the nucleus of another phenol mol., mixts. of phenol ethers and esters have been heated with $AlCl_3$. When 2,6-$Me_2C_6H_3OMe$ and *p*-MeC_6H_4OAc are so taken, the products are xylenol, cresol, 5,2-$Me(HO)C_6H_3Ac$ and 3,5,4-$Me_2(HO)C_6H_2Ac$. With a mixt. of 2,4,6-$Me_3C_6H_2OMe$ and *p*-$MeC_6H_4CO_2CH_2Cl$, the 2 free phenols, $ClCH_2CO_2H$ and unchanged ethers are the sole products. Had R. substitution occurred, ketones derived from the ethers should have been formed. Other evidence is obtained which shows that reciprocal exchange of acyl groups occurs in some cases under the conditions of a Fries change. 2-Hydroxymesitylene and *p*-MeC_6H_4OBz or the acetate of

the former and p-MeC_6H_4OH, do not interact in absence of catalysts at 200°, while a mixt. of the last 2 substances, when heated at 150° for 0.75 hr. in the presence of $AlCl_3$ affords only 5,2-Me(HO)C_6H_3Ac and hydroxymesitylene. On the other hand, when a mixt. of 2-hydroxymesitylene and p-MeC_6H_4OBz is heated for 0.25 hr. at 150° with $AlCl_3$, 2,4,6-$Me_3C_6H_2OBz$ is formed, together with the 2 free phenols and 5,2-Me(HO)-C_6H_3Bz, while under similar conditions a mixt. of 2,4,6-$Me_3C_6H_2OAc$ and p-MeC_6H_4-OBz affords some of the benzoate of the mesitylenol, together with BzOH, 5,2-Me(HO)-C_6H_3Bz and 5, 2-Me(HO)C_6H_3Ac. A mixt. of 2,4,6-$Me_3C_6H_2OAc$ and 3,4-$ClMeC_6H_3OBz$ gives free phenols, 3,5,2-ClMe(HO)C_6H_2Ac, 3,5,2-ClMe(HO)C_6H_2Bz and the 2,4,6-$Me_3C_6H_2OBz$. Since reciprocal esterification under Fries conditions would explain R.'s test expt., it is concluded that the Fries rearrangement is an intra- and not an inter-mol. change. C. J. West

Alkylation and acylation in the presence of titanium tetrachloride. G. Stadnikov and L. Kashtanov. Lab. Coal Research, Moscow. *Ber.* **61B**, 1389–91(1928); cf. *C. A*. **22**, 1774.—Zonev has shown that certain compds. of $SnCl_4$ with ethers in C_6H_6 decomp. in such a way that 1 of the alkyl groups of the ether replaces one or two H atoms of the C_6H_6 nucleus, and S. and his co-workers have found that ketones of the thiophene series can be synthesized from acyl chlorides and thiophenes with $SnCl_4$. It was of interest to det. whether $TiCl_4$ can be used for analogous syntheses. $PhCH_2$-OEt with $TiCl_4$ in C_6H_6 decomps. into $PhCH_2Cl$, which reacts further with the C_6H_6 to form mono- and disubstituted benzenes. That this is the mechanism of the reaction is confirmed by the fact that preformed $PhCH_2Cl$ reacts in the same way with C_6H_6 in the presence of $TiCl_4$. iso-AmOAc and iso-AmOBz, on the other hand, do not react with C_6H_6, and neither does $(iso\text{-}Am)_2O$. Nor was it possible to prep. Ph_2CO from BzCl, C_6H_6 and $TiCl_4$, whereas thiophene gives benzothienone almost quant. C_6H_6 as such does not react with $TiCl_4$. From 72 g. $PhCH_2OEt$, 350 g. C_6H_6 and 50 g. $TiCl_4$ gently boiled 10 hrs. were obtained 46.5 g. CH_2Ph_2, 17.8 g. m- and p-$C_6H_4(CH_2Ph)_2$ and 8.7 g. residue; 20 g. $PhCH_2Cl$, 200 g. C_6H_6 and 29 g. $TiCl_4$ gave 9.4 g. CH_2Ph_2, 1.8 g. m- and 1.6 g. p-$C_6H_4(CH_2Ph)_2$ and 6.6 g. residue. C. A. R.

Aromatic hydrocarbons in the naphtha of Turzowá. Hugo Novák and Jos. Hubáček. *Chemický Obzor* **1**, 10–5; *Chem. Zentr.* **1927**, II, 1318.—N. and H. det. the aromatic hydrocarbons in a crude oil from Turzowá. The phys. properties and the results of Engler-Ubbelohde's distn. test are given. Having compared different methods N. and H. finally employ sulfonation for isolating the aromatic hydrocarbons from the resp. fractions obtained by distn. of the naphtha when raising the temp. in intervals of 10°. The naphtha distg. at and below 165° consists of 16% of aromatic hydrocarbons; this value equals 3.8% of the original crude oil. Of all the aromatic hydrocarbons present, PhH, which prevails in the fractions up to 105°, makes up 25%, and MePh 13%. Xylenes make up the biggest part of this naphtha with 40%. The rest of 22% are higher (b. p. over 150°) homologous compds. of PhH, which were not identified more exactly. The distillates between 175° and 205° are practically free of aromatic hydrocarbons. G. Schwoch

Alkali organic compounds. W. Schlenk and Ernst Bergmann with Bertha Benedikt, Ottilie Blum, Celina Bresiewicz, Ilse Rodloff, Johannes Appenrodt, Karl Ehninger, Hans Ender, Robert Israel, Angelo Knorr, Theodor Köhler, Alfred Michael, Eugen Müller, Ernst Rubens, Wilhelm Schmidt-Nickels, Wilhelm Stoffers, Alfred Wiegandt and Harry Willstädt. **I. Products of the addition of alkali metal to several carbon-carbon linkages.** *Ann.* **463**, 1–97 (1928); cf. *C. A*. **8**, 1580.—In the addn. of Na or other alkali metals to the C : C bond, 2 types of compds. are to be distinguished: (I) $Ph_2C{:}CPh_2$ gives $Ph_2CNaCNaPh_2$ and (II) $2Ph_2C{:}CH_2$ gives $Ph_2CNaCH_2CH_2CNaPh_2$. Besides the 2 cases, which show that an unsatd. C atom is capable of adding Na only if it is linked to an aryl group, several cases are found in which the C atom binds alkali, even if not attached to an aryl group. In these cases the C atom is associated with an unsatd. group. Under definite conditions the C atoms of the C_6H_6 ring add Na; $C_6H_4Ph_2$, for example, forms the complex $PhNaC_6H_4NaPh$. In the following work Na and Li were used; in most cases Li adds more rapidly to the unsatd. C atom. H_2O and the alcs. hydrolyze the metal complexes, replacing the metal by H; CO_2 replaces the Na by the CO_2Na group; with MeI, compds. of type I give the original hydrocarbon, while with those of type II, substitution occurs; with Hg, compds. of type I lose Na, forming the original hydrocarbon and Na-Hg, while compds. of type II do not react; R'NCS reacts with compds. of type I to give the original hydrocarbon and R'NNaCSCSNNaR', while with compds. of type II, substitution occurs, the group (S:)CNNaR' being introduced, which on hydrolysis with H_2O yields thioamides. With PhNCO, polymeriza-

tion occurs (formation of $(PhNCO)_3$). $Ph_2CNaCNaPh_2$ (III) in Et_2O, shaken with Hg, gives $Ph_2C{:}CPh_2$ (IV), but not quant. The alkali compds. of anthracene and Hg gives the pure hydrocarbon, while the di-Na deriv. (V) of $Ph_2C{:}CHCH{:}CPh_2$ gives $Ph_2C{:}CH_2$. III and EtNCS give IV and the compd. $C_6H_{10}N_2S_2Na_2$; PhNCS likewise regenerates IV. V and EtNCS give, after hydrolysis of the Na salt with H_2O, the *dithioethylamide* of *1,1,4,4-tetraphenylbutane-1,4-dicarboxylic acid*, m. 223°; hydrolysis with concd. HCl at 160° gives the free acid, m. 290° (decompn.). III and PhBr give IV and Ph_2; BzH gives IV, BzONa and $PhCH_2OH$; furfural gives IV, Na pyromucate and furyl alc.; $(HCHO)_3$ gives IV, HCO_2Na and *2,2,3,3-tetraphenylbutane-1,4-diol*, m. 187°; BzOPh gives IV, Ph_2 and BzONa; other esters react in an analogous manner; BzCl gives IV and benzil; α-$C_{10}H_7COCl$ gives IV and α,α'-naphthil; $ClCO_2Me$ gives IV and $(CO_2Me)_2$; phorone gives IV and $(Me_2CHCH_2)_2CO$; $PhNH_2$ gives IV and PhNHNa; NO gives IV and $Na_2N_2O_2$; NH_3 and CO do not react with III; SO_2 gives $Ph_2C(SO_2Na)C(SO_2Na)Ph_2$. V and BzH give *1,2,2,5,5,6-hexaphenylhexane-1,6-diol*, sinters 176°, m. 212°; furfural gives *1,6-difuryl-2,2,5,5-tetraphenylhexane-1,6-diol*, m. 212–3°. BzOPh gives *1,4-dibenzoyl-1,1,4,4-tetraphenylbutane*, m. 195–6°. BzCl gives *1,2,2,5,5-pentaphenyl-1-hydroxycyclopentane*, m. 179° (10% yield) and the *Bz deriv.*, m. 240°. $COCl_2$ gives *2,2,5,5-tetraphenylcyclopentan-1-one*, m. 176°. Phorone gives $(Ph_2CHCH_2)_2$. NOCl gives $(Ph_2C(OH)CH_2)_2$, m. 204°, which, crystd. from AcOH, apparently forms an inner anhydride, m 190–1°. In the systematic investigation of alkali addn. to the C·C bond, it was found that no reaction occurs with $Ph_2C{:}CHMe$, $Ph_2C{:}CMe_2$, $PhCH{\cdot}CMe_2$, $PhMeC.CMe_2$ or $Ph_2C{:}C(CH_2Ph)_2$; this behavior is explained by the assumption that the double bond is not in the place as indicated by the formulas given, for in all other cases the C:C bond adds Na if it is linked with 2 Ph groups. If the compd $Ph_2C{\cdot}CMe_2$ is ascribed an isomeric constitution, $Ph_2CHC{:}CH_2Me$, no alkali addn would be expected; this assumption is supported by the observation that $Ph_2C{\cdot}CHCH_2Ph$ does not add Na but does react when 1 H atom is substituted and that $Ph_2C{\cdot}CMe_2$, which does not react with Na, slowly reacts with Li, giving a brown alkali complex. $(Me_2NC_6H_4)_2C{:}C(C_6H_4NMe_2)_2$ reacts quickly with Na, giving a bluish green powder; EtOH gives $[(Me_2NC_6H_4)_2CH]_2$, m 334°; CO_2 gives the *Na salt*, $C_{36}H_{40}O_4N_4Na_2$, pale yellow, unchanged at 300°, which gives a deep dark blue aq. soln., the color disappearing on heating. *Dibiphenylmethylcarbinol*, from the ketone and MeMgI, m. 147°, gives a bluish red soln. in concd. H_2SO_4; warming with AcOH and H_2SO_4 on the H_2O bath gives *dibiphenylethylene*, m. 211°; in Et_2O Na gives a deep blue soln., the Na compd. sepg. as crystals with a metallic luster, CO_2 gives *α,α'-tetrabiphenyladipic acid*, does not m. 300°; Hg gives the original hydrocarbon; EtOH gives *1,1,4,4-tetrabiphenylbutane*, m. 236°. $Ph_2C{\cdot}CHPh$ gives a brownish black Et_2O soln., decompd. by EtOH to Ph_2CHCH_2Ph, m. 56°; CO_2 gives the *anhydride* of *triphenylsuccinic acid*, m. 115°. Ph_2C CPhMe gives a blood-red Et_2O soln. with Na, decompd. by EtOH to $Ph_2CHCHPhMe$, m. 73–5°; Li behaves similarly. $Ph_2C{:}CHMe$ does not react with Na; K gives a very little dark ppt, which reacts with CO_2 to give a *compd.*, $C_{17}H_{14}O_3$, m 164° and a 2nd *compd.*, $(C_{16}H_{16}O_2)_n$, m. 259°. Me_2CHCO_2Me and PhMgBr give *diphenylisopropylcarbinol*, b_{12} 169–70°, m. 47°; the action of HCl, followed by C_5H_5N, gives *1,1-diphenyl-2,2-dimethylethylene*, $Ph_2C{:}CMe_2$ or $Ph_2CHCMe{:}CH_2$, b_{14} 152–3°; Li gives after 4 weeks a brown soln, which reacts with PhNCS to give the *thioanilide* of *diphenyl-2-propenylacetic acid*, pale yellow, m. 161°. *1,3,3-Triphenyl-2-benzylpropan-3-ol*, m. 100°; *1,1-diphenyl-2,2-dibenzylethylene*, m. 78°, results from the chloride and C_5H_5N; this does not react with Na. $Ph_2C{:}CHCH_2Ph$ or $Ph_2CHCH{\cdot}CHPh$, b_{10} 222°, reacts with Na during 2 months to give a red ppt., decompd. by EtOH to give the original hydrocarbon, thus indicating substitution, not addn. Ph_2C $CHCHPh_2$ reacts very slowly with Na; Li reacts much more quickly, giving a dark brown soln.; decompn. with EtOH gives *1,2,3-triphenyldihydroindene*, m. 153°; CO_2 gives *1,2,3-triphenyldihydroindenecarboxylic acid*, m. 271°; *Me ester*, m. 151°. With soda-lime the acid gives the *compd.*, $C_{27}H_{22}$, m. 126°. That only 1 Li atom reacts is further shown by the formation with EtNCS of the *compd.* $C_{30}H_{27}NS$, m. 193°. The Li compd. and I give $Ph_2C{:}CHCH{\cdot}CPh_2$, m. 200°, Ph_2CH_2 and a hydrocarbon, m. 221°. $Ph_2C{\cdot}CPhCN$ and Na in Et_2O give a bluish violet, then brownish black and finally a deep blood-red soln., decompd. by EtOH to Ph_2CHCH-PhCN, m. 102–3°. PhCN and Na give a dark red soln., decompd. by EtOH to cyaphenin, $(PhCN)_3$, and a green oil, whose *perchlorate* has the compn. $C_7H_7N\ HClO_4$. Diphenylfulvene reacts almost immediately with Na in Et_2O, giving a clear red soln., decompd. by EtOH to *3-benzohydrylcyclopentadiene*, m. 36.5°, and by CO_2 to the *acid*, $(CH{:}CH)_2C(CO_2H)C(CO_2H)Ph_2$, m. 173–5° (decompn.). Dimethylfulvene and Na in Et_2O give a red ppt., which reacts with EtOH to give $[(CH{:}CH)_2C(CO_2H)CMe_2]_2$,

whose *Me ester* m. 194°. Diphenylbenzofulvene and Na give a dark red Et_2O soln., which reacts with EtOH to give 3-benzohydrylindene, m. 114°, and with CO_2 to give *1-[diphenylmethanecarboxylic acid]-indene-1-carboxylic acid,* m. 177° (decompn.). $(C_6H_4)_2C:C(C_6H_4)_2$ and Na give a deep reddish yellow soln., decompd. by EtOH to $(C_6H_4)_2CHCH(C_6H_4)_2$, m. 240°, and by CO_2 to *dibiphenyleneethanedicarboxylic acid,* m. 240°. $(C_6H_4)_2C:CHPh$ and Na give an insol. brick-red powder, decompd. by EtOH to *sym-diphenyldifluorenylethane,* m. 321°, and by CO_2 to *β,β'-diphenyl-α,α'-dibiphenyleneadipic acid,* m. 240° (decompn.). Furfurylidenefluorene and Na give a reddish brown addn. product, which yields with EtOH *sym-di-α-furyldi-9-fluorenylethane,* m. 238–42° and gives an orange-red color with H_2SO_4. Cinnamylidenefluorene and Na give a reddish brown addn. product, decompd. by EtOH to *sym-distyryl-di-9-fluorenylethane,* m. 254–5°; this is identical with the compd. obtained by Thiele and Henle (*Ann.* **347**, 303(1906)) by reduction with Al-Hg and moist Et_2O. There also results a *hydrocarbon,* m. 204°. Dixanthylene and Na give a bright scarlet-red soln. which is decompd. by EtOH to 9,9'-dixanthyl and by CO_2 to *9,9'-dixanthyl-9,9'-dicarboxylic acid,* pale yellow, decomps. 189°; the *Na salt* is yellow. $(PhCH:CH)_2C:CPh_2$ gives a wine-red color with Na in Et_2O, decompd. by EtOH to *1,5-diphenyl-3-benzohydryl-1,4-pentadiene,* pale yellow, m. 151–2°, and by CO_2 to *1,1-distyryl-2,2-diphenylethane-1,2-dicarboxylic acid,* m. 215° (decompn.). $(PhCH:CHCH\cdot CH)_2C:CPh_2$ and Na give at first a deep green, then a greenish blue soln., decompd. by EtOH to *1,9-diphenyl-5-benzohydryl-1,3,6,8-nonatetraene,* m. 140°, and by CO_2 to the corresponding *dicarboxylic acid,* $(PhCH.CHCH:CH)_2C(CO_2H)C(CO_2H)Ph_2$, yellow, m. 127° (decompn.). $(Me_2C:CH)_2C\cdot CH_2$ and Na give a deep reddish yellow soln., giving with EtOH *2,9-dimethyl-4,7-di-[β,β-dimethylvinyl]-2,8-decadiene,* pale yellow, b_{58} 195–6°; CO_2 gives the *Na salt,* $C_{22}H_{32}O_4Na_2$, pale yellow. PhC ⋮ CPh is best obtained by oxidizing $(PhCNNH_2)_2$ with HgO; Na gives a dark brown soln. in Et_2O, decompd. by EtOH to a compd. m. 295°; the reaction is better studied with Li, which gives a dark brown soln. and ppt; EtOH decomps. this to *1,2,3-triphenylnaphthalene,* m. 151°, which is not catalytically reduced by Pd-$BaSO_4$ but with Na and AmOH gives an amorphous product, m. 75°, contg. 4 additional H atoms; from a reaction product which had stood several years, an *isomer,* m. 192°, was isolated, which is also not catalytically reduced. CO_2 gives *2,3,4-triphenylnaphthalene-1-carboxylic acid* (VI), m. 258° (decompn.); the C_6H_6 mother liquor gives the *anhydride* of *3,4-dihydro-2,3,4-triphenylnaphthalene-3,4-dicarboxylic acid,* m. 270°. PhSCN gives the *thioanilide* of VI, yellow, m. 280–1°. The action of Hg or I upon the Li complex gives the *hydrocarbon,* $C_{28}H_{20}$, m. 227°. $Ph_2C\cdot CCl_2$ or $Ph_2C:CBr_2$ with Li (concd. soln.) gives a *hydrocarbon,* $C_{28}H_{22}$, m. 183°, catalytically reduced to the *hydrocarbon,* $C_{28}H_{24}$, m. 182° (also obtained by the action of Li and hydrolysis); in dil. soln there results the hydrocarbon $C_{28}H_{20}$, m. 152°, transformed by Li and hydrolysis to the hydrocarbon, $C_{28}H_{20}$, m. 192°. *Anisildihydrazone,* m. 118°, on oxidation gives $MeOC_6H_4C$ ⋮ CC_6H_4OMe, m. 145°; concd H_2SO_4 gives a bluish red color; Li reacts very slowly. Diphenyldiacetylene is polymerized by Li or Na. The action of Li upon phenanthrene (purified through the picrate) gives a dark brown, Et_2O-insol. product, transformed by EtOH into a liquid *dihydrophenanthrene* (VII), b_{15} 168–70°, catalytically reduced by Pd-$BaSO_4$ to a mixt. of 2 *tetrahydrophenanthrenes,* b_6 140–5° and 145–9°. From the distn. residue of VII there is isolated a new *dihydrophenanthrene,* m. 71–3°. The action of Na upon phenanthrene gives a reddish violet soln., giving with CO_2 *9,9',10,10'-tetrahydro-9,9'-diphenanthryl-10,10'-dicarboxylic acid,* m. 226°. Diphenylphenanthrene and Li (or Na) give a brown-red soln., decompd. by EtOH to *9,10-dihydro-9,10-diphenylphenanthrene,* m. 130–1°, and by CO_2 to the *anhydride* of the corresponding *9,10-dicarboxylic acid,* pale yellow, m. 221°. $C_{10}H_8$ gives with Li a reddish violet soln. and a dark brownish violet ppt., yielding with EtOH 1,4-dihydronaphthalene, m. 28°, and with CO_2 the corresponding *1,4-dicarboxylic acid,* m. 226–7°. Ph_2 and Li give a brown ppt., yielding with EtOH a *dihydrodiphenyl,* b_{10} 110° catalytically reduced to cyclohexylbenzene. CO_2 gives *1,4-dihydrodiphenyl-1,4-dicarboxylic acid,* m. 266°. *p*-$C_6H_4Ph_2$ and Na give a grayish black ppt., decompd. by CO_2 to *1,4-diphenyl-2,5-cyclohexadiene-1,4-dicarboxylic acid,* sinters 240°, m. 264° (decompn.). 1,2,4,5-$C_6H_2Ph_4$ gives a deep dark blue soln. with Na, decompd. by EtOH to the *1,2-dihydro deriv.,* m. 208–10°; Pd and H give $C_6H_2Ph_4$. CO_2 gives an *acid,* $C_{32}H_{24}O_4$, m. 230° (decompn.); the soln of the Na salt is easily changed to $C_6H_2Ph_4$. **II. New knowledge in the field of the stereochemistry of carbon.** *Ibid* 98–227.—PhCH:CHCH:CHPh and Na give a dark brownish violet ppt. [PhCHNaCH:CHCHNaPh]; with EtOH this yields a *1,4-diphenyl-2-butene,* b_{13} 176°, isomeric with the known compd., m. 45° (probably *cis-trans* isomerism); with CO_2 there results *1,4-diphenyl-2-butene-*

1,4-dicarboxylic acid, m. 220°; Hg or dry air gives the original hydrocarbon. Li behaves similarly to Na. $Ph_2C:CHCH:CPh_2$ and Na give a dark bluish violet soln., which gives with EtOH *1,1,4,4-tetraphenyl-2-butene* (I), m. 140.5°, does not decolorize Br; reduction gives $(CH_2CHPh_2)_2$, m. 119°. CO_2 gives the corresponding *1,4-dicarboxylic acid,* m. 262° (decompn.), which decolorizes $KMnO_4$ in Na_2CO_3; *di-Me ester,* m. 148–8.5°. MeI and Hg give $Ph_2C:CHCH\cdot CPh_2$. Li behaves similarly. Reduction of $Ph_2C:CHCH:CPh_2$ with Na-Hg gives I. $Ph_2C:CHMgBr$ and $HgBr_2$ give 40% of *bis[β,β-diphenylvinyl]mercury* (II), m. 140.5°, and some *β,β-diphenylvinylmercuric bromide,* m. 158–9°; the latter is the principal product with a larger amt. of $HgBr_2$. II and Na after 8 days give a brownish violet product, which with CO_2 gives the above acid, m 262°; EtOH gives an *isomer* of I, m. 123–4°. $(C_6H_4)_2CNaCNa(C_6H_4)_2$ in Et_2O has Λ 7.1 × $10^{-5}\Omega^{-1}$ per mol. in cc.; $(PhCH:CH)_2CNaCNaPh_2$, 1.6 × 10^{-8}; the latter was the more deeply colored. PhCH:CHPh gives a di-Na compd., yielding with CO_2 the *acid,* $C_{16}H_{14}O_4$, m. 229–30° (decompn.); *di-Me ester,* m. 219°. Hg gives PhCH:CHPh. Li gives a reddish brown product, which gives with EtOH $(PhCH_2)_2$ and with Hg PhCH:CHPh. CO_2 gives the *acid,* $C_{16}H_{14}O_4$, m. 241° (decompn.); *di-Me ester,* m. 191°. The acid m. 229° is *meso-*$(CHPhCO_2H)_2$. K behaves similarly to Na. Iso-stilbene and Li give a reddish brown soln., giving with Hg stilbene and with CO_2 the acid, m. 241°. Na gives a bluish violet soln. and a steel-blue ppt., which gives with EtOH or Hg stilbene and with CO_2 the acid, m. 229°. $(CPhMe)_2$ and Na give a yellow-brown soln. after 5 days; EtOH gives $(CHPhMe)_2$, m. 124°, also obtained by catalytic reduction of $(CPhMe)_2$. CO_2 gives $(HO_2CCPhMe)_2$, which does not m. 296°. The Li compd. forms a brownish violet ppt., which gives with EtOH the same compd. as the Na compd., but with CO_2 gives an isomeric *sym-diphenyldimethylsuccinic acid,* m. 296°. Hg gives the original hydrocarbon. $Ph(PhC_6H_4)CO$ (50 g.) and 43 g. PCl_5, heated 1 hr. at 160°, give 56 g. of the *dichloride,* m. 72°; 30 g. of this and 60 g. Cu bronze in 300 cc. C_6H_6, heated 4 hrs., give 19 g. *sym-diphenyldibiphenylethylene,* m. 255°, and 16 g. of an isomeric *hydrocarbon,* m. 218°. Either isomer with Na gives a reddish violet compd., which yields with EtOH *sym-diphenylbiphenylethane,* m. 247°, and the *isomer,* m. 205–6°. Catalytic reduction of *p,p'*-dimethoxytolan in 1,4-dioxane gives a mixt. of *p,p'-dimethoxyisostilbene,* m. 37°, and the dibenzyl deriv., m. 123°; on distn. at 14 mm., some dimethoxystilbene, m. 212–3°, is formed, which also results by the action of Hg upon the Li deriv. The di-Na deriv. of dihydroanthracene gives with CO_2, as has been previously described, a 9,10-dihydroanthracene-9,10-dicarboxylic acid, m. 286° (decompn.), which is termed the α-acid (III); if the aq. soln. of the Na salt is heated before pptn. with acid, there results the *β-acid* (IV), which crysts. with 1 H_2O, which is lost at 16 mm. and 113°, and it then m. 294° (decompn.); a small amt. of IV may be extd. with Et_2O from the aq. filtrate from III. The Li compd. with SO_2 gives a 3rd isomer, termed the *γ-acid* (V), which results whether the aq. soln. is or is not heated, and m. 297° (decompn.). III with CH_2N_2 gives a *di-Me ester,* m. 162.5–3°; IV and V give the same *di-Me ester,* m. 163.5–5°; the 2 esters are characterized by their different behavior toward the cathode rays. IV and V differ in that while V appears to cryst. with H_2O, this is lost at room temp., while the H_2O of crystn. of IV is stable at room temp. The 2 acids also differ in the relative ease of transformation into III. Esterification of III with MeOH and HCl gives a mixt. of the α- and β-esters. Heating the α-ester at 200° gives the β-ester. The α-9,10-dihydroanthracene-9-carboxylic acid, m. 207°, resulting from the Na deriv. of anthracene and CO_2, gives a *Me ester* (VI), m. 94–6°; with a higher concn. of the anthracene, there results the β-acid (see below) and *9,9',10,10'-tetrahydro-9,9'-bianthryl-10,10'-dicarboxylic acid,* isolated as the *di-Me ester,* m. 267°; the free acid does not m. 370°. Reduction of anthroic acid gives *β-9,10-dihydroanthracene-9-carboxylic acid,* sinters 182°, m. 197°; reduction of the corresponding ester gives VI. 9,10-Diphenylanthracene, for which a method of prepn. is given, is reduced by Na-Hg or Na or AmOH to a dihydro deriv., m. 208°; Na gives a deep blue, then violet soln , which yields with EtOH a *dihydro deriv.* (VII), crystg. as needles, m. 199°, and as tablets, m. 190°, a mixt. of which m. 175°; these are polymorphic forms. Both dihydro derivs. give the same *tetrahydro deriv.*, does not m. 300°. The action of CO_2 upon the Na deriv. gives the *α-9,10-diphenyl-9,10-dihydroanthracene-9,10-dicarboxylic acid,* m. 299° (decompn.), if the aq. soln. of the Na salt is heated and then cooled before acidification; if the soln. is acidified without heating, there results the *β-acid* (VIII), m. 277° (decompn.); esterification gives the same *di-Me ester,* m. 201°. The Li deriv. and CO_2 give the *γ-acid* (IX), m. 282°, which also gives the above di-Me ester. *9,10-Diphenyl-9,10-dihydro-9,10-dimethoxyanthracene,* m. above 300°; Na and CO_2 give the above β-acid; Li and CO_2 give the γ-acid.

9-Methylanthracene gives at first a deep blue soln. with Na, changing to green; EtOH gives methyldihydroanthracene. 9-Phenylanthracene, m. 152°, from phenylanthrone on reduction with Na and AmOH, gives α-phenyldihydroanthracene, m. 87°, also obtained from the action of Na and EtOH. 9-Phenylanthracene from anthrone is reduced by Na and AmOH to β-phenyldihydroanthracene, m. 123°, but Na, followed by EtOH, gives the α-deriv., m. 87°. The β-deriv. with Na gives a brownish yellow soln. which yields with EtOH the α-deriv. The 9,9′-bianthryl, m. above 360°, on reduction with Na and AmOH, gives a tetrahydro deriv., m. 255°; Na gives a deep violet addn. product, decompd. by EtOH to the same tetrahydro deriv., while CO_2 gives the *tetra-Na salt*, $C_{32}H_{18}O_8Na_4$. Ph_2CHNa and 9-bromoanthracene give a little *9,9′-bianthryl*, m. 304°, reduced by Na and AmOH to the above tetrahydro deriv. Phenylanthrone (7.5 g.) and excess PhMgBr give 5.5 g. *9,10-diphenyl-9,10-dihydro-9-hydroxyanthracene*, m. 202–3°; heated in $C_6H_4Me_2$ with K and MeI, there results nearly quant. the *Me ether*, m. 226°. The action of K in $C_6H_4Me_2$ for 2 hrs., followed by MeI, EtI, Me_2CHI, $ClCH_2OMe$, $PhCH_2Cl$, or best, Me_3CCl, gives *diphenylanthracene* (X), m. 214°, isomeric with the yellow form, m. 247°. Na gives a dirty yellow-brown soln. yielding VII with EtOH and VIII with CO_2. Hg gives X. The Li compd. with Hg gives X, with CO_2 IX. Phenylanthrone and o-MeC_6H_4MgBr give *9-phenyl-10-tolyl-10-hydroxy-9,10-dihydroanthracene*, m. 201°, colored deep green by concd. H_2SO_4; K and Me_3CCl give *9-phenyl-10-o-tolylanthracene*, m. 172–3° and showing in boiling BzOEt a reversible yellow color. Phenylanthrone and MeMgI give *9-phenyl-10-methyl-10-hydroxy-9,10-dihydroanthracene*, pale red, m. 162°; K and Me_3CCl give the known 9-methyl-10-phenylanthracene, m. 116°. PhMgBr and 1-methylanthraquinone give *1-methyl-9,10-diphenyl-9,10-dihydro-9,10-dihydroxyanthracene*, m. 236°; with HCO_2Na and HCO_2H this gives *1-methyl-9,10-diphenylanthracene*, yellow, m. 194°. The 2-Me deriv. was similarly prepd. Phenylmethoxyanthrone and o-MeC_6H_4MgBr give *9-phenyl-10-o-tolyl-9-methoxy-10-hydroxy-9,10-dihydroanthracene*, m. 168°; *9-phenyl-o-tolylanthracene*, pale yellow, m. 257–8°; the corresponding *m-tolyl derivs.* m. 209–10° and 182–3°, resp. Fluorene and EtLi give $(C_6H_4)_2CHLi$, orange colored; Ph_3CNa gives the Na deriv., which is sol. in Et_2O (yellow soln.); with CO_2 either salt gives *β-fluorene-9-carboxylic acid*, m. 232°; both this and the α-acid, m. 222°, give the same *Me ester*, m. 63°, and also the di-Me ester of dibiphenylenesuccinic acid, m. 234°. The latter acid with MeOH and H_2SO_4 gives after 8 days, the Me ester, m. 63°. The Li salt and Ph_2CHBr in C_6H_6 give 9-benzohydrylfluorene, m. 217°; the Na salt gives the same compd. However, Ph_2CHNa and 9-chlorofluorene give the isomeric *compd.*, m. 187°, whose constitution is established by shaking with K for 4 weeks and then treating with CO_2, giving α-fluorene-9-carboxylic acid, Ph_2CHCO_2H and Ph_2CH_2. *Fluorenone di-Me acetal*, m. 87–8°. Na gives the *Na deriv.* of *methoxyfluorene*, red prisms, which yields with CO_2 *9-methoxyfluorenecarboxylic acid*, m. 172–3°; the Me ester m. 124°, and on sapon. gives the isomeric *acid*, m. 192° (decompn.). The Li salt behaves similarly. The Na salt and MeI give 9-methyl-9-methoxyfluorene, m. 92–3°; with Na there results a golden yellow ppt., with Li a brownish yellow powder; with CO_2 both give the above acid, m. 193°. *Phenylfluorenol benzyl ether*, m. 141.5°, gives the same acid. Ph_2CO and Na in Et_2O, shaken 10 days and then treated with Ph_2CCl_2, give α-benzopinacolin, m. 207°. Fluorenone and Na give a green soln.; Ph_2CCl_2 gives *9,9-diphenyl-10-phenanthrone*, m. 193–4°; fluorenone dichloride gives 9,9-biphenylene-10-phenanthrone, m. 257°. $Ph_2C(ONa)Na$ and 9,9-dichlorofluorene in Et_2O give 2 kinds of reaction products (conditions for each not detd.); if the Et_2O residue is solid, there are obtained 2 stereoisomeric *biphenylenediphenylethylenes*, m. 224–5° and 213°, sepd. by crystg. from benzine; if the residue is oily, the product is *biphenylenediphenylethylene oxide*, m. 228°; the mother liquor gives a mixt. of the 2 hydrocarbons. Reduction of the hydrocarbons gives 9-benzohydrylfluorene, m. 214°. The lower-melting isomer, treated with Na and then with Hg, gives the higher-melting compd. The oxide, heated with AcCl for 6 hrs., gives a mixt. of the 2 hydrocarbons. Fluorenone and iso-PrMgCl give *9-fluorenyldimethylcarbinol*, m. 124°; the Et_2O soln., satd. with HCl at −20° and then heated with C_5H_5N for 3 hrs., gives *biphenylenedimethylethylene*, light yellow, m. 113°, which is very unstable. The Li deriv. of fluorene and Ph_2CO give a mixt. of $(C_6H_4)_2C{:}CPh_2$, m. 213–4°, and $(C_6H_4)_2CHC(OH)Ph_2$, m. 213–4°. Diphenylindone and PCl_5 give the *compd.*, $C_{21}H_{14}OCl_2$, m. 135–6°; 5 g. of the indone, 3.5 g. $PhNH_2$ and 0.2 g. $PhNH_2.HBr$, heated 10 min., give the *compd.* $C_{27}H_{19}N$, brown, m. 201°. *Benzophenone d-bornylimide*, m. 170°, b_{14} 215–8°, [α] 7.57° (0.3435 g. in 10 cc. $CHCl_3$), results by heating Ph_2CO, *d*-bornylamine and a little dil. HBr at 160° for 0.5 hr. Catalytic reduction of diphenylindone with Pd-$BaSO_4$ gives a mixt. of *2,3-diphenyl-1-hydroxydihydroindene*, m. 146° (not sharp, because

of oxidation; the colorless soln. in BzOEt turns yellow on heating); and *2,3-diphenyl-1-ketodihydroindene*, m. 100°. *Diphenylindone d-bornylimide*, bright yellow, m. 123°, [α] 124° (0.2422 g. in 10 cc. $CHCl_3$); decompn. with dil. HCl gives the optically active indone, whose phenylhydrazone has [α] −1.85° (0.2710 g. in 10 cc. $CHCl_3$). Catalytic reduction of 1,1,3-triphenylindene with Pd-$BaSO_4$ or with P and HI gives the dihydro deriv., m. 112–3°, while the action of Na, followed by MeOH, gives the isomeric *dihydro deriv.*, m. 133°. 1-Benzohydrylidene-3-phenylindene, reduced with Na and AmOH, gives *1-benzohydryl-3-phenyldihydroindene*, m. 137°. The action of Na, followed by decompn. with EtOH, gives a yellow *compd.*, $C_{28}H_{22}$, m. 171°, which is reduced by Na and AmOH to the compd., m. 137°, and a colorless *compd.*, $C_{28}H_{22}$, m. 131°. Reduction with Na-Hg and EtOH gives the dihydro deriv., m. 171°, and a 3rd *isomer*, $C_{28}H_{22}$, insol. in PrOH, m. 180°. Stereoisomers of indene-1-carboxylic acid could not be obtained. III. **New kind of compound with bivalent carbon.** *Ibid* 228–80.—Directions are given for the prepn. of $Ph_2C:C:CPh_2$; this reacts with Na, K and Li. The compd. with Na seps. as metallic needles; with EtOH this gives $Ph_2CHCH:CPh_2$, m. 125°; with CO_2 there results the *di-Na salt* of a *dicarboxylic acid*, $C_{28}H_{20}O_4Na_2$, which on treatment with H_2O gives the *Na salt*, crystg. with 3 H_2O, of *diphenyl[β,β-diphenylvinyl]acetic acid* (I), m. 179°. The structure of this acid was established by the following synthesis: *Et β-phenylcinnamate*, b_{17} 207°, and PhMgBr give $Ph_2C(OH)CH:CPh_2$; the *Et ether*, m. 104°; Na followed by CO_2 gives the acid, m. 179°. The Na compd. with MeI at −20°, $CH_2(CH_2Br)_2$ and I give $Ph_2C:C:CPh_2$; Hg has no action. $ClCH_2OMe$ gives *1,1,3,3-tetraphenyl-4-methoxy-1-butene* (II), m. 124°. $ClCO_2Me$ gives the *Me ester*, m. 117–8°, of I, also obtained from I and CH_2N_2. EtNCS gives the *thioethylamide* (III) of I, m. 173°. MeI at room temp. gives *1,1,3,3-tetraphenyl-1-butene* (IV), m. 111°. $Ph_2C(OEt)CH:CPh_2$ and Na give the complex $Ph_2C-NaCH:CPh_2$; with MeI this gives IV; $ClCH_2OMe$ gives II, easily reduced to the *butane*, m. 87.5–9°; EtNCS gives III; $CH_2(CH_2Br)_2$ gives the *compd.* $Ph_2C(CH_2CH_2CH_2Br)CH·CPh_2$, m. 120–1°; I gives a *hydrocarbon*, $C_{27}H_{22}$, m. 129–30°, of unknown structure. $Ph_2C·C:CPh_2$ and Li give a deep violet soln., which gives with EtOH *1-benzohydryl-2-phenyl-3,4-benzocyclobutane* (V), m. 184°; the reaction with H_2SO_4 is characteristic, a pale rose color being formed at first, which changes to a bright bluish blood-red; the latter color results at once upon adding a drop of concd. HNO_3. A Br titration of V indicates that less than 1 mol. Br is consumed, but the action of slightly more than 1 mol. Br in $CHCl_3$ gives the *tri-Br deriv.*, m. 212° (decompn.). V and Na give a blood-red soln.; with CO_2 this gives the acid, $C_{27}H_{21}CO_2H$, which does not m. 300°. LiEt and V give $C_{27}H_{21}Li$ and C_2H_6. Catalytic reduction of V gives the *hydrocarbon*, $C_{27}H_{28}$, m. 170°. The Li complex of $Ph_2C:C·CPh_2$ gives with Hg the *hydrocarbon* $C_{27}H_{20}$ (VI), m. 186°. VI is not catalytically reduced, but Na and AmOH or P and HI give a *hydrocarbon*, $C_{27}H_{22}$, m. 167–8°; Na gives an isomeric *hydrocarbon*, m. 103°. Diphenylindone and PhMgBr give 1,2,3-triphenylinden-1-ol, m. 129–30°, reduced by P and HI in AcOH to *1,2,3-triphenyldihydroindene*, m. 153°. The Me ether, m. 153°, shaken with Na for 8 days, gives 1,2,3-triphenylindene, m. 135°. *Diphenylbenzylacetyl chloride*, m. 90–1°, with $AlCl_3$ in CS_2 gives an oily 2,2-diphenylindan-1-one, which with PhMgBr gives *1,2,2-triphenyldihydroinden-1-ol*, m. 172–3°, giving an orange-yellow color with H_2SO_4; P and HI give *1,2,2-triphenyldihydroindene*, m. 142°, also obtained by the action of Ac_2O and H_2SO_4 at 140° upon *1,2,2,3-tetraphenylpropan-1-ol*, m. 141–2°. $PhCH_2C(OH)PhC(OH)Ph_2$, m. 139°, with AcCl gives a mixt. of Ph_3CCOCH_2Ph, m. 111–2°, *1,2,2,3-tetraphenylpropan-1-one*, m. 151° (also obtained from $Ph_2C(CH_2Ph)OMe$, Na and BzCl), and a *compd.*, $C_{27}H_{22}O$ m. 126–7°, probably $\underbrace{C_6H_4.CH_2.C(OH)Ph.CPh_2}$. $MeC_6H_4CPh_2Na$ and CO_2 give *diphenyl-o-tolylacetic acid*, m. 228°, decomps. 240° (*Et ester*, m. 100–1°); *chloride*, m. 86.5–7°; C_5H_5N gives the *anhydride*, $C_{42}H_{34}O_3$, m. 197°. *Me dibenzyl-o-carboxylic acid*, b_{25} 195–6°; PhMgBr gives *o-[β-phenethyl]triphenylcarbinol*, m. 103°; *chloride*, m. 128–30°; quinoline gives *1,1,2-triphenyldihydroindene*, m. 83°. Reduction of benzohydrylideneanthrone with Na and AmOH gives *9-benzohydryl-9,10-dihydroanthracene*, m. 207.5°. $(C_6H_4)_2CHCH_2CO_2Et$, b_{16} 207–9°, with PhMgBr give *1,1-diphenyl-2-fluorenyl-1-ethanol*, m. 121°, which gives a dark reddish brown color with concd. H_2SO_4; the Et_2O soln. satd. with HCl and then boiled with C_5H_5N gives *1,1-diphenylene-3,3-diphenyl-2-propene*, m. 111–2°; concd. H_2SO_4 gives a yellow color; reduction with Na and AmOH gives *1,1-diphenylene-3,3-diphenylpropane*, m. 107°. Phenylmethoxyanthrone (VII) is reduced by Na and AmOH to 9-phenyl-9,10-dihydroanthracene, m. 87–8°. The *hydrazine* of VII m. 142°; concd. H_2SO_4 gives a blood-red color; heated with EtONa at 140°, there results phenylanthracene. 9,10-Diphenyl-

9-methoxy-10-hydroxy-9,10-dihydroanthracene, shaken with Na for 8 days and then treated with MeI, gives the *9-Me deriv.*, m. 183–4°; reduction with P and HI by heating 3 hrs. in AcOH gives *9,10-diphenyl-9,10-dihydro-9-methylanthracene*, m. 171°. **VII** and $PhCH_2MgCl$ give *9-phenyl-10-benzyl-9-methoxy-10-hydroxy-9,10-dihydroanthracene*, m. 151°, giving a deep green color with concd. H_2SO_4; reduction with P and HI gives *9-phenyl-10-benzylanthracene*, m. 151°; on shaking with Na for 3 days, followed by EtOH, there results *9,10-dihydro-9-phenyl-10-benzylanthracene*, m. 119°. **IV. Addition products of sodium to carbon-nitrogen and nitrogen-nitrogen double bonds.** *Ibid* 281–322.—PhMeC:NPh and Na give at first a brick-red color, changing to a deep reddish brown [PhMeCNaNNaPh]; EtOH gives PhMeCHNHPh, b_{11} 170–2°; CO_2 gives a *salt*, which becomes a smear in the air; the free acid could not be isolated. $(C_6H_4)_2C$:NPh gives a brown soln. with Na, from which EtOH gives 9-anilinofluorene, m. 124°; CO_2 gives *9-anilinofluorene-9-carboxylic acid*, crystg. with $1H_2O$, m. 220° (decompn.). PhCH:NEt gives a dark red soln. with Na, from which EtOH gives $PhCH_2NHEt$, b_{15} 82-3°. PhMeC:NCH_2Ph and Na give a brick-red soln.; EtOH gives $PhMeCHNHCH_2Ph$, b_{19} 176°. $(C_6H_4)_2C$:NH and Na give a bluish red soln. (no evolution of H); reaction with CO_2 probably gives $(C_6H_4)_2C(CO_2Na)NHCO_2Na$ and unchanged $(C_6H_4)_2C$:NH; the salt is extd. with H_2O and upon warming gives 9-aminofluorene, m. 257° (decompn.); in 1 decompn. with EtOH, there was isolated difluorenylamine, m 187°. Me_2C:NPh and Na give a greenish yellow soln., which gives with EtOH 2,2,3,3-tetramethylindoline, m. 39°; the Na complex has the formula $PhNNaCMe_2CMe_2NNaPh$. Similarly, MeEtC·NPh and Na give an intensely yellow soln., which gives with EtOH *3-methyl-2,3-diethylisoindole*, pale yellow, b_{12} 152-3°, whose *methiodide*, pale yellow, m. 242°. $(PhCH:N)_2CHPh$ and Na give a red soln., from which a colorless ppt. seps.; with EtOH this gives dihydroamarine (see below). Acridine reacts promptly with Na, giving a yellowish green mass, gradually turning during 5 days to a violet; EtOH gives a mixt. contg. 35% of dihydroacridine, m. 170°, and an insol. product (recrystd. from $PhNMe_2$ with great loss), which may be *tetrahydro-C,C'-biacridyl*, $C_{26}H_{20}N_2$, m. 270°; C_5H_5N gives a colloidal soln.; BzCl gives a *compd.*, $C_{40}H_{28}O_2N_2$, m. 305° and is completely decompd. by heating 12 hrs. with 30% KOH. The Na compd. with CO_2 gives the same high-melting compd. and *9,10-dihydroacridine-9-carboxylic acid*, m. 229° (decompn.). 9-Phenylacridine and Na give a deep bluish violet soln., which, decompd. with EtOH, gives dihydrophenylacridine, m. 162.5°, and with CO_2 gives *9,10-dihydro-9-phenylacridine-9-carboxylic acid*, m. 225–7° (decompn.). Amarine and Na give a light red addn. product, nearly insol. in Et_2O; EtOH gives *dihydroamarine*, m. 274–5°, also obtained by the catalytic reduction of amarine; the *HCl salt*, m. 285°. Lophine and Na give a colorless ppt. giving unchanged lophine on decompn. with H_2O. $PhCOC_6H_4Ph$, transformed into the K or Na salt, and treated with phenazine, yields a quinhydrone of phenazine and its di-K or di-Na salt, deep green or violet; treatment with H_2O gives a *mixt.* of phenazine and dihydrophenazine, blue, m. 224-6°. PhMeC:NN:CPhMe gives a red compd. with Na; the decompn. product with it is an oil; CO_2 gives a *salt*, $C_{20}H_{16}O_8N_2Na_4$. Ph_2C·NN CPh_2 solns. are colored violet-black with Na; EtOH gives *sym*-dibenzohydrylhydrazine, m. 138°; CO_2 gives the *salt*, $C_{30}H_{20}O_8N_2Na_4$. $(C_6H_4)_2C$:NN:C-$(C_6H_4)_2$ gives a deep brown soln., decompd. by EtOH to difluorenylhydrazine, m. 174-5° (yield usually small and variable); CO_2 gives α-fluorene-9-carboxylic acid. PhCH:NN CHPh and Na give ruby-red prisms, $(C_{14}H_{12}N_2Na)_2$; EtOH gives the *compd.* $C_{28}H_{26}N_4$, m. 117-8°; CO_2 gives the *salt*, $C_{30}H_{24}O_4N_4Na_2$. Ph_2C·$NHNH_2$ and Na give a yellow soln., decolorized by EtOH with the formation of $Ph_2CHNHNH_2$, isolated as the *methiodide*, m. 226.5°. $(Ph_2C:NNPh)_2$ gives at first a red soln. with Na, finally changing to blue-violet, the compd. being split at the -N.N- linkage, giving, with EtOH, Ph_2NH and Ph_2CHNH_2, whose HCl salt m. 298° (decompn.). Ph_2C:-NNHPh and Na give a deep violet-blue soln.; with EtOH there results Ph_2CHNH_2, $PhNH_2$ and *benzohydrylidenebenzohydrylamine*, m. 153°, whose structure is established by hydrolysis with dil. HCl. Decompn. of the violet soln. with CO_2 gives *benzohydrylammonium carbonate*, m. 103° (decompn.); heating at 56° gives a *compd.*, $C_{15}H_{17}NO_2$, m. 145°. Ph_2C:NNPhMe gives at first with Na a reddish brown, then a blue-violet color; MeOH gives the amine, m. 153°. MeN·NMe and Na give a pale yellow soln.; EtOH gives MeNHNHMe, m. 163°; CO_2 gives the *Na salt* of $[NMe(CO_2H)]_2$. Ph_2-NN:$NNPh_2$ and Na give as the final products N and Ph_2NH. $Ph_2CNaNNaPh$ with Hg, MeI, BzCl, BzOPh and PhSCN give Ph_2C:NPh. The di-Na deriv. of Ph-CH:NPh, however, gives with PhSCN the *compd.* $C_{40}H_{34}N_4S_2$ $(CHPhNPhCSNHPh)_2$, m. 263°; MeI gives *di-N-methylanilinodiphenylethane*, m. 127°; Ph_2CCl_2 gives Ph_2C:-CPh_2; BzOEt gives the compd. PhCH.NPh.NPh.CHPh, m. 153–4°; BzH gives

the same product; Hg does not react. **V. Triphenylmethyl- and diphenylmethylsodium.** *Ibid* **464**, 1–21(1928).—Ph_3CNa and N_2O in Et_2O give the red *Na triphenylmethyl diazotate*, $Ph_3CN:NONa$, which is sensitive to CO_2 and with EtOH gives Ph_3COH and N_2; with H_2O, N_2 is also evolved but only yellow smeary products are obtained. Continued action of N_2O gives a yellow ppt. of a mixt. of compds. NO and Ph_3CNa give a dark bluish red primary product, which contains about 1.5 NO per 1 Ph_3CNa; if the treatment with NO is continued until the soln. is light yellow and the excess NO removed by N, there results *Na isonitrosotriphenylmethylhydroxylamine*, $Ph_3CN(ONa)NO$ or $Ph_3CN(:O):NONa$, which crysts. with 1 EtOH or 1 C_6H_6, which are lost *in vacuo;* the salt then m. 240–50° (decompn.); the Ag salt is yellowish white, the Hg salt reddish brown, the Cu salt pale violet, the Fe salt egg-yellow and the Pb salt white. With acids the compd. splits off N_2O, giving Ph_3COH. In the presence of a little Na-Hg there results an isomeric *compd.*, which also crysts. with 1EtOH; it also forms salts, which appear identical with the above; however, with acids the isomer gives at first the compd. $Ph_3CN_2O_2H$, which on heating or standing decomps. into Ph_3COH and N_2O. The 2 forms may be *syn-* and *anti*-isomers. Ph_3CCOCl and Ph_3CNa in Et_2O give a dark brownish red *ketyl*, $C_{39}H_{30}ONa$, from which H_2O gives *hexaphenylacetone*, m. 80–1°; with Ph_3CNa, the pure ketone gives the ketyl deriv. Ph_3CNa and EtNCS give the *ethylamide* of *triphenylthioacetic acid*, m. 143°; the *phenyl deriv.* (from PhNCS) m. 157°; the *allyl deriv.* m. 131–2°. Ph_3CNa and PhNCO give $Ph_3CCONHPh$, m. 170°; $ClCO_2Et$ gives Ph_3CCO_2Et, m. 119–20°; AcCl gives Ph_3CH, as do Me_2CHCl and Me_3CCl. $ClCH_2OMe$ and Ph_3CNa give *2,2,2-triphenylethyl Me ether*, m. 137°. Ph_2CHNa and PhNCS give $Ph_2CHCSNHPh$, m. 182°; Ph_2CO gives Ph_2CHCPh_2OH, m. 236°; fluorenone gives *9-benzohydrylfluoren-9-ol*, m. 183°. A method is given for the prepn. of pure Ph_2CHNa. **VI. Alkali addition products from diaryl ketones.** *Ibid* 22–34.—Diphenylindone in Et_2O reacts with Na powder with the formation of a dark reddish brown Et_2O-insol. product; with Et_2O this yields diphenylhydrindone, m. 100°; excess of MeI yields *2,3-diphenyl-2,3-dimethylindan-1-one*, m. 166–7°, while CO_2 gives *2,3-diphenylindan-1-one-3-carboxylic acid*, yellow, m. 181° (decompn.). The deep blue soln. of the di-Na compd. of $PhCOC_6H_4Ph$, shaken with Hg, quickly changes to the bluish green of the ketyl; the mono-Na deriv. and PhNCS give a reddish orange ppt., $C_{14}H_{10}N_2S_2Na_2$, which, with dil. H_2SO_4, gives $(CO_2H)_2$ and the ketone. The di-Na deriv. apparently gives the same compd. The di-Na deriv. of BzPh and $PhCH_2Cl$ give $Ph_2(PhCH_2)COH$, m. 87–8°; the di-Na deriv. of $PhCOC_6H_4Ph$ and $PhCH_2Cl$ give *phenylbiphenylbenzylcarbinol benzyl ether*, $PhC_6H_4(PhCH_2)PhCOCH_2Ph$, m. 164–5°. $PhCH_2MgCl$ and $PhCOC_6H_4Ph$ give *phenylbiphenylbenzylcarbinol*, m. 129–30°; an attempt to prep. the above $PhCH_2$ ether by the action of $PhCH_2Cl$ and HCl upon the alc. gave *1,2-diphenyl-1-biphenylethylene*, m. 134–5°. If instead of $PhCH_2Cl$, MeI is used, there is formed *p-tolyl biphenyl ketone*, m. 133–4°, also obtained from p-MeC_6H_4COCl and Ph_2 with $AlCl_3$ in CS_2; with Na this gives a deep green and then a bluish violet color, decompd. by EtOH to give *p-phenyl-p′-methylbenzohydrol*, m. 110°; that the mother liquor from the above ketone contains $Ph(PhC_6H_4)MeCOH$ is shown by heating the AcOH soln. with a little concd. H_2SO_4, *asym-phenylbiphenylethylene*, m. 94°, being obtained. This was synthesized by the action of MeMgI upon $PhCOC_6H_4Ph$, the primary product being *phenylbiphenylmethylcarbinol*, m. 105–6° (*Me ether*, m. 117°), but if the MeMgI is boiling when the ketone is added, the above ethylene is obtained. Because it was originally thought that the *p*-tolyl ketone was *o-phenylbenzophenone*, m. 90°, this compd. was synthesized. *o-Phenylbenzoyl chloride*, b_{18} 169°, was transformed into the amide, m. 176°, and then into *o-phenylbenzonitrile*, b_{13} 175°, m. 41°, which with PhMgBr gives the ketone. **VII. Various degradation reactions with alkali metals.** *Ibid* 35–42.—$Ph_2C(OMe)_2$, shaken with Na or Li for 3 weeks, gives a red-violet soln.; addn. of EtOH gives a deep green, then an egg-yellow soln., from which ppts. Ph_2MeCOH, m. 79–80°; this indicates the intermediate product $Ph_2MeCONa$. CO_2 likewise ppts. Ph_2MeCOH from the red-violet soln. There is also formed some $Ph_2C(ONa)Na$, since addn. of acid to the CO_2-treated soln. gives a small amt. of $Ph_2C(OH)CO_2H$, m. 150°, and its Me ether, m. 102°. $[Ph_2C(OPh)]_2$ and Na give a reddish yellow soln., from which was isolated Ph_3COH. 9-Phenyl-10-methoxyanthracene and Na give a dark olive-green soln., which, decompd. with EtOH, gives 9,9′,10,10′-tetrahydro-10,10′-diphenyl-9,9′-bianthryl, m. 260°. 9,10-Dimethoxyanthracene and Na give a dark brown soln., from which ppts. a yellowish brown product; 1 Me group reacts with Na giving MeNa and the mono-Na deriv.; with BzCl this gives *anthrahydroquinol Me ether benzoate*, yellowish brown, m. 226–7°, and with I, dimethoxydianthranone, m. 236–8°, and anthraquinone.

C. J. West

N-Methyl derivatives of 2-phenylnaphthylene-1,3-diamine. CHARLES STANLEY GIBSON, WM. SIMPSON KENTISH AND JOHN LIONEL SIMONSEN. Univ. of London. *J. Chem. Soc.* **1928**, 2131–42; cf. Lees and Thorpe, *C. A.* **2**, 125.—2-Phenylnaphthylene-1,3-diamine (I), m. 113.5°; Ac deriv., m. 175°. I (15 g.) in 200 cc. MeOH and 150 g. Me_2SO_4, gradually treated with 600 cc. 25% KOH, give 30% of the α-*N,N'*-di-Me deriv. (II), m. 170°, and 35% of the tetra-Me deriv. (III), m. 122°; by means of the NO deriv. there were also isolated 6% of the tri-Me deriv. and 25% of the β-*N,N'*-di-Me deriv. Further methylation of I gives III quant. II and Ac_2O give a *mono-Ac deriv.*, m. 203°. *p-Toluenesulfonyl deriv.*, m. 219–20°, could not be acetylated or further methylated. *d*-Hydroxymethylenecamphor gives the *compd.* $C_{29}H_{32}ON_2$, m. 167–8°, α_{5461} 406.5°; an Ac deriv. could not be prepd.; the compd. is homogeneous and could not be sepd. into 2 isomers; the salts from *d*-camphor-10-sulfonic acid and *d*-α-bromocamphor-π-sulfonic acid were also homogeneous. I and *p*-$MeC_6H_4SO_2Cl$ in C_5H_5N, heated 4 hrs. on the H_2O bath, give principally the *α-di-p-toluenesulfonyl deriv.* (IV), dimorphic, m. 203–5° and 188–9° (α_1-form); there also results a small amt. of the β-isomer, m. 173–5°, and some *tri-p-toluenesulfonyl deriv.*, m. 153–4°. The *N,N'-di-Me deriv.* of IV, m. 305°, on hydrolysis with AcOH-H_2SO_4 for 2 hrs., gives the pure β-*N,N'*-di-Me deriv. (V) of I, m. 159–60°; Me_2SO_4 converts this into III; *di-Ac deriv.*, m. 207–8°; the *di-d-methylenecamphor deriv.*, m. 277–9°, α_{5461} 650.1°, could not be resolved; other camphor derivs. behaved similarly. II and V give the same dinitrosoamine. The tri-Me deriv. of I, m. 104–5°, yields an *Ac deriv.*, m. 178°. II is considered as the *cis-*, V as the *trans*-form. C. J. WEST

Action of silver on diphenyl-*tert*-butylethinylbromomethane. PAUL L. SALZBERG AND C. S. MARVEL. Univ. of Illinois. *J. Am. Chem. Soc.* **50**, 2840–4(1928); cf. *C. A.* **22**, 2362.—It has been shown that hexa-*tert*-butylethinylethane reacts with liquid Na-K and with liquid Na-Hg to give the corresponding alkali metal derivs. of tri-*tert*-butylethinylmethyl; in a further study of the effect of the C ⋮ C groups on the stability of hexa-substituted ethanes, the closely related tetraphenyldi-*tert*-butylethinylethane was used. The Grignard reagent from $Me_3CC \vdots CH$ and EtMgBr reacts with Ph_2CO to give *diphenyl-tert-butylethinylcarbinol*, $b_{0.4-0.5}$ 132–5°, m. 66.5–7.5°, d_{25}^{25} 1.0124, n_D^{25} 1.5550 (supercooled); *bromide*, m. 58.5–60.5° (cor.). Shaken with Ag in an atm. of air or N, the *hydrocarbon* (I), $C_{38}H_{38}$, m. 153.5–5° (cor.), results; it does not absorb O. In an atm. of O this reaction does not produce a hydrocarbon but O is absorbed very rapidly by the reaction mixt. I reacts with liquid Na-K and with 40% Na-Hg to produce colored alkali metal derivs. but apparently the mol. is not cleaved as would be expected if it has the structure of tetraphenyldi-*tert*-butylethinylethane (II). The suggestion is made that II is formed by the action of Ag on the bromide but that it rapidly dissocs. and rearranges to some more stable structure. If O is present in large amts. the free radicals produced by the dissocn. of II are oxidized before this rearrangement occurs. C. J. WEST

Nature of the alternating effect in carbon chains. XXVIII. The preparation and some properties of benzyl fluoride. CHRISTOPHER K. INGOLD AND EDITH HILDA INGOLD. Univ. of Leeds. *J. Chem. Soc.* **1928**, 2249–62; cf. *C. A.* **22**, 2929.—$PhCH_2Cl$ and Me_3N in EtOH heated at 45° for several hrs., the $PhCH_2NMe_3Cl$ pptd. with Et_2O, the aq. soln. treated with Ag_2O, the filtrate neutralized with 20% HF and evapd. to a viscous sirup and then distd. in vacuum, give 60% of *benzyl fluoride*, b_{14} 40–40.5°, b_{30} 55–6°, b_{64} 70–1°, b_{118} 85–6°, b_{244} 100–100.5°, b_{760} 139.9° (cor.), m. −35°, does not fume in the air and is not lachrymatory; $d_4^{25.3}$ 1.02278, $n^{25.3}$ 1.48481, 1.48919, 1.49294, 1.50014, 1.50927, 1.50967 for λ = 6563, 5893, 5461, 4861, 4358, 4340. Comparative values are given for PhMe. F has by far the lowest refraction values of the halogens and it differs sharply from the others in contributing practically nothing to dispersion. The introduction of a F atom into the aromatic nucleus causes a larger restraint on the electrons and hence a larger increase in the frequency governing dispersion than that produced by the entrance of a F atom into the side chain. Further evidence pointing in a similar direction was obtained by a study of the ultra-violet absorption of $PhCH_2F$, for which curves are given for *M*/100 to *M*/1600 EtOH soln. When the fluoride is touched with a rod moistened with concd. H_2SO_4, a violet reaction sets in and rapidly spreads through the mass, much heat being generated and HF copiously evolved; the product is a white glass, $(C_7H_6)_x$; a similar product is obtained with concd. HF and also when the fluoride decomps. spontaneously in glass vessels; the action seems to be autocatalytic; the kind of glass is an important factor and no losses have occurred when Jena glass has been used for distn. The fluoride (11 g.), boiled for 6 hrs. with 400 cc. 10% K_2CO_3, gives 4.4 g. fluoride, 3.4 g. $PhCH_2OH$ and a mixt. of the 2; Ph-

CH_2Cl gave only $PhCH_2OH$. With boiling EtOH and Zn about 90% of the fluoride is recovered unchanged. With 33% $EtOH-NMe_3$ there is formed only 5% of the quaternary salt. EtONa gives a mixt. of unchanged fluoride and Et ether. Nitration in Ac_2O yields the following proportions of mono-NO_2 derivs.: *o*-28.1, *m*-17.5, *p*-54.4%; *p-NO_2 deriv.*, m. 38.5°. Distn. of *o*-, *m*-, or *p*-$O_2NC_6H_4NMe_3F$ gave the corresponding $O_2NC_6H_4CHO$. **XXIX. Further experiments bearing on the problem of the ortho-para ratio in aromatic substitution.** C. K. Ingold and Charles C. N. Vass. *Ibid* 2262-7.—In the nitration of *p*-FC_6H_4Cl the addn. of H_2SO_4 increases the proportion of 1,2,4-compd. relatively to its isomer (1,3,4-deriv.) by 31% and the addn. of fuming H_2SO_4 caused an increase of 64%. The m. p. curve of 2,5-$FClC_6H_3NO_2$ and 5,2-$FClC_6H_3NO_2$ is given. Their behavior with MeOH-MeONa is also reported.

C. J. West

Hydrogenation of nitrobenzene with platinum black. G. Vavon and Krajčinović. *Compt. rend.* **187**, 420-2(1928).—Equal wts. of $PhNO_2$ (I), and BzH are hydrogenated in alc. or AcOH with Pt black. After 1.8 moles of H_2 are added the reaction is stopped and 40% PhN(:O):CHPh (II), m. 112°, is obtained (indicating that in the reduction of I with Pt black it passes to PhNHOH). **II** is easily reduced to $PhN(OH)CH_2Ph$, m. 86°. Similar results are obtained using piperonal in place of BzH. Nitrotoluenes similarly treated did not give any condensation products.

D. H. Powers

Nitration of chlorobenzene. O. Yu. Nagidson and I. Kalishevskii. *Trans. sci. chem.-pharm. inst.* (Moscow) **6**, 17-20(1923).—PhCl and nitrating acid afford chiefly *p*-$ClC_6H_4NO_2$, while $NaNO_3$ and H_2SO_4 afford chiefly the *o*-compd. The latter reagent readily gives 2,4-$(O_2N)_2C_6H_3Cl$ at a higher temp.

B. C. A.

Reduction of aromatic nitro compounds with sodium alcoholates. C. M. Suter and F. B. Dains. Univ. of Kansas. *J. Am. Chem. Soc.* **50**, 2733-9(1928).—With the exception of *o*-halonitro derivs., Na and PrOH, BuOH and iso-AmOH gave a yield of from 50-90% reduction products, consisting of amine and azoxybenzenes; the *o*-halonitrobenzenes condense with the CH_2 grouping of the alcs. with the formation of NH_2 acids. $PhCH_2OH$ reduced the NO_2 compd. to azoxybenzene and was fully oxidized to BzH and BzOH. The aliphatic alcs. were oxidized to acids of less C content, among them HCO_2H. A table is given showing the results of 34 expts. with various halonitro compds. and alcs. *o*-$ClC_6H_4NO_2$ and PrONa in C_6H_6 give 40% *o*-$ClC_6H_4NH_2$ and *α-o-chloroanilinopropionic acid*, m. 150°, also prepd. from *o*-$ClC_6H_4NH_2$ and $MeCHBrCO_2H$; soly. in H_2O: 30°, 0.094 g. per 100 cc.; at b. p., 0.44 g.; $CuSO_4$ gives a green color; heating above 165° causes the loss of CO_2. *N-Ethyl-o-chloroaniline*, b_{726} 219° (cor.), d_4^{25} 1.104, d_4^{35} 1.0911; *HCl salt*, m. 138-9°. *α-Ethyl-α-o-chlorophenyl-β-phenylurea*, m. 144°. *α-o-Chloroanilinobutyric acid*, m. 95°; *isovaleric acid*, m. 75°. *α-o-Bromoanilinopropionic acid*, m. 162-4°; *butyric acid*, m. 83°. *α-2,5-Dichloroanilinopropionic acid*, m. 163°. *α-o-Chloroanilinophenylacetic acid*, yellow, m. 160°. Results of 19 expts. with *o*-halonitrobenzenes are given, showing the yield of amine, azoxy compd. and amino acid.

C. J. West

Formation of bases from carbonyl compounds. A. Skita and F. Keil. Techn. Hochschule, Hanover. *Ber.* **61B**, 1452-9(1928).—Reduction of Schiff bases to secondary amines gives different yields, depending on the nature of the base. Thus, while PhCH:NPh is reduced almost quant. to $PhCH_2NHPh$ by the ordinary reducing agents, the yields decrease very rapidly with increasing mol. wt. of the radicals attached to the N and with Schiff bases contg. unsatd. residues, as these unstable substances often easily escape reduction as the result of polymerization or hydrolysis. For this reason recourse had already been had in some cases (*e. g.*, in the prepn. of $Ph(CH_2)_3NHEt$ from PhCH:CHCH:NEt; cf. *C. A.* **21**, 2882) to catalytic reduction with colloidal Pt in acid soln. But this method also gives no appreciable quantities of basic reduction products with more unstable imino compds. (*e. g.*, *citralmethylamine* (I)); evidently the hydrolytic action of the acids is more rapid than the hydrogenation velocity. Whereas a Schiff base in neutral soln. or suspension takes up either no H or only an insufficient quantity, addn. of NH_3 to the colloidal Pt results in a vigorous absorption of H and the formation of the corresponding secondary base. Amines exert a similar catalytic influence. In fact, in many cases it is better not to start with the preformed Schiff bases but with a mixt. of their components (aldehyde and amine). Thus, citral and a slight excess of $MeNH_2$ yielded considerably more *N*-methyl-3,7-dimethyloctylamine (II) than did I. Under the proper conditions citral in NH_4OH suspension gives no primary amine but only the secondary *bis*[*3,7-dimethyloctyl*]*amine* (III). While other aldehydes of high mol. wt. yield secondary amines in the same way (*e. g.*, diheptylamine (IV) from enanthaldehyde), the initial members of the aldehyde series (AcH,

EtCHO) yield the tertiary amines. Ketones with NH_3 or primary amines in aq. suspension also yield secondary bases. *Citralcyclohexylamine*, b_{18} 170–2°, gives in alc. with colloidal Pt and AcOH *N-cyclohexyl-3,7-dimethyloctylamine*, b_{14} 151–3°; *HCl salt*, m. 154–5°; *picrolonate*, m. 174–5°. *Citralisoamylamine*, b_{20} 150–4°, in neutral alc. soln. yields *N-isoamyl-3,7-dimethyloctylamine*, b_{17} 142–5°; *HCl salt*, m. 168–9°; *picrolonate*, m. 186–7°. *Citralethylamine*, very unstable, b_{12} 113–5°, in neutral soln. yields at most 2% of *N-ethyl-3,7-dimethyloctylamine* (V) but 9 g. of the base in 50 cc. alc. with 3 cc. of 25% NH_3 and 100 cc. of 1% Pt (contg. 1 g. gelatin) absorbs the calcd. quantity of H in 1.5 hrs. at room temp. under 3 atm. excess pressure and yields 5 g. V, b_{13} 135–7°; *HCl salt*, m. 102–3°; *NO deriv.*, oil; *picrolonate*, m. 196–7°. I, b_{13} 107–9° (in H). III, from 16.2 g. citral and colloidal Pt (prepd. from 30 cc. H_2PtCl_6, 20 cc. 1% colloidal Pt and 20 cc. 10% gum arabic) suspended in 40 cc. H_2O, treated with 7.5 cc. 24% aq. NH_3 and hydrogenated at room temp. under 3 atm. excess pressure, b_{15} 191–3°; *HCl salt*, m. 141–2°. IV, m. 30°, b. 270–2°; HCl salt, m. 250°, is *not* hygroscopic. $(iso\text{-}Pr)_2NH$, from Me_2CO in aq. NH_4OH, b. 84°; HCl salt (5 g. from 15 g. Me_2CO), m. 212–4°; *picrate*, m. 140°. MeCOEt gives $(MeEtCH)_2NH$, b. 230–3°, whose HCl salt is not deliquescent but, when pure, is stable in the air and m. 215–6°. Et_2CO gives $(Et_2CH)_2NH$. From cyclohexanone is obtained *dicyclohexylamine*, b_{20} 128–30°; *HCl salt*, m. around 340°. MeCOEt and aq. $EtNH_2$ give EtNHCHMeEt, b. 96–8°. *N-Ethylcyclohexylamine*, from cyclohexanone and $EtNH_2$, b. 161°.

C. A. R.

Attempted synthesis of β-m-aminophenylethylamine. A. K. De. *J. Indian Chem. Soc.* **5**, 29–31(1928).—*m*-Aminocinnamic acid, m. 180°, prepd. from *m*-nitrocinnamic acid, m. 200 1° (colorless), yields *m-acetamidocinnamic acid*, m. 235°, which in turn gives *β-m-acetamidophenylpropionic acid*, m. 162°, on reduction with Na-Hg. The failure of the prepn. of the amide of the last-named precluded the synthesis of $m\text{-}H_2NC_6H_4CH_2CH_2NH_2$ by this method. It was also not found possible to reduce *m,ω-dinitrostyrene*, m. 123–4°, prepd. from $m\text{-}O_2NC_6H_4CHO$ and $MeNO_2$, to the amine.

B. C. A.

Preparation of furanethylamine. Teijiro Yabuta and Katsuji Kambe. Tokyo Imp. Univ. *Proc. Imp. Acad.* (Japan) **4**, 120–1(1928).—Furylethylamine is conveniently prepd. by reducing β-nitro-2-furylethylene (action of NO fumes on β-2-furylacrylic acid in C_6H_6) with Al-Hg to 2-furylacetaldoxime and the latter with Na-Hg.

C. J. West

Synthesis of *dl*-2,5-dihydroxyphenylalanine. Kinsaburo Hirai. Akad. Nagasaki. *Biochem. Z.* **189**, 88–91(1927).—Gentisaldehyde, 7 g., prepd. from $o\text{-}HOC_6H_4\text{-}CHO$, was methylated in 10% NaOH soln. with Me_2SO_4. The product was condensed with glycine anhydride. The resulting 2,5-dimethoxybenzalglycine anhydride was refluxed 8 hrs. with red P and HI, the soln. dild , filtered and pptd. with $Pb(OAc)_2$, the PbI_2 filtered off, the soln. made alk. with NH_4OH and treated with H_2S, filtered and evapd. nearly to dryness in a current of CO_2. dried *in vacuo*, dissolved in H_2SO_4 and crystd. in the ice chamber. Yield 0.5 g., m. 203–4°. E. H.

5-Bromo-1,3-dimethyl-4-aminobenzene and some of its derivatives. E. Bureš and A. Mandel-Borgmannová. Charles Univ., Prague. *Časopis Československého Lékárnictva* **7**, 257–69(1927).—By the action of Br on $2,4\text{-}Me_2C_6H_3NH_2$ at ordinary temp. and pressure, without catalysts, and protected from sunlight, is formed 5-bromo-1,3-dimethyl-4-aminobenzene (I), m. 49–50° (H_2SO_4 salt, m. 183°; picrate, m. 122°; Bz deriv., m. 183°; Ac deriv., m. 197–8°). I was converted to 5-bromo-1,3-dimethylbenzene, b. 204°, which on oxidation gave 5-bromo-3-methylbenzoic acid, m. 178°. I was converted to 5-bromo-1,3-dimethyl-4-hydroxybenzene, b. 231° (Me ether, b. 140°; Et ether, b. 142°; Ac deriv., b. 257–8°). I was converted by Gattermann's reaction into 4,5-dibromo-1,3-dimethylbenzene, b. 257°. I was converted to 5-bromo-1,3-dimethyl-4-benzonitrile, m. 218°, which on hydrolysis gave 6-bromo-2,4-dimethylbenzoic acid, m. 186° (Me ester, m. 174°; Et ester, m. 176°; Pr ester, m. 178°; iso-Bu ester, m. 182°; Am ester, m. 181°). William J. Husa

2,5,6-Trichloro-1,3-dimethyl-4-aminobenzene and some of its derivatives. E. Bureš and J. Borgmann. Charles Univ., Prague. *Časopis Československého Lékárnictva* **7**, 270–80(1927).—By the action of Cl on $2,4\text{-}Me_2C_6H_3NHAc$, m. 123°, dissolved in glacial AcOH, at ordinary temp. and pressure, without catalysts, is formed 2,5,6-trichloro-1,3-dimethyl-4-acetamidobenzene, m. 208.5° (I). The introduction of the 3 Cl atoms stabilizes the mol. and lowers the basicity of the amine. I on sapon. yields 2,5,6-trichloro-1,3-dimethyl-4-aminobenzene, m. 204° (II) (Bz deriv., m. 174–5°; HCl salt, m. 217°). II was converted to 2,5,6-trichloro-1,3-dimethyl-4-hydroxybenzene, m. 174° (Me ether, m. 91.5°; Et ether, m. 53.5°; Ac ester, m. 86°). Other

derivs. of II prepd. were 2,5,6-trichloro-1,3-dimethylbenzene, m. 179.5°; 2,5,6-trichloro-1,3-dimethyl-4-benzonitrile, m. 218°, which on hydrolysis gave 3,5,6-trichloro-2,4-dimethylbenzoic acid, m. 191.5°; and 2,4,5,6-tetrachloro-1,3-dimethylbenzene, m. 219°. WILLIAM J. HUSA

Solubility of diphenylamine in water, in alcohol and in other organic solvents. LOUIS DESVERGNES. *Ann. chim. anal. chim. appl.* **10**, 253–5(1928).—The d. at 15°, color of the soln. and amt. dissolved by 100 g. of solvent at 0°, 28° and 40° are given for 12 solvents. The following are, resp., the d. at 15° and amt. dissolved at 28°: AcOEt, 0.9048, 306.8; AcMe, 0.7998, 298.6; EtOH, 0.7944, 95.84; MeOH, 0.8055, 123.0; C_6H_6, 0.8826, 278.0; $CHCl_3$, 1.489, 206.3; Et_2O, 0.7193, 324.8; pyridine, 0.9805, 306.9; CS_2, 1.272, 314.1; CCl_4, 1.601, 1.22.6; toluene, 0.8733, 227.7; *m*-xylene, 0.8683, 163.4. Ph_2NH is very slightly sol. in hot water, but readily sol. in most org. solvents. The solvent should not contain any free Cl_2 and an alc. soln. should not be exposed to light. W. T. H.

Comparative mechanism of deamination of some aromatic amines and dehydration of the corresponding alcohols. JEANNE LÉVY, PAUL GALLAIS AND DINAH ABRAGAM. Paris Univ. *Bull. soc. chim.* **43**, 868–81(1928).—Deamination with HNO_2 gave *1,1-diphenyl-2-propene*, b. 293°, n^{20} 1.596, from *1,1-diphenyl-2-propylamine*, m. 62–3°; *HCl deriv.* m. 280–2°; *Ac deriv.* m. 107–8°; *Bz deriv.* m. 203–4°. The same treatment gave *2-phenyl-1-anisyl-1-propene*, m. 86–7°, from *1-phenyl-1-anisyl-2-propylamine*, m. 63–4°; *HCl deriv.* m. 215–6°; *Bz deriv.* m. 181–2°. Distn. of *1,1-diphenyl-2-propanol*, m. 62° (*Ac deriv.* m. 77–8°), in the presence of pumice satd. with H_2SO_4 gave *methylstilbene* and $Ph_2CHCH{:}CH_2$. Under these conditions *1-phenyl-2-anisyl-1-propene*, m. 103–4°, was formed from *1-phenyl-1-anisyl-2-propanol*. From these results it is shown that rearrangement may or may not take place during deamination and that the nature of the groups dets. the mechanism of deamination and dehydration. Since the products are not the same in the 2 cases, NH_2 removal does not take place through the alc. when $Ph_2CRCHRN_2OH$ decomps. to form an ethylenic compd. The authors are led to believe that in those cases where the alc. can be isolated, it is present in consequence of a secondary reaction. The following compds. are reported in the course of the work: *1-anisyl-1-phenyl-1-propanol*, b_{13-4} 20°, n^{20} 1.583; the *2,1,1-compd.* b_{18} 210–5°; *1,1-diphenyl-2-propenoxide*, b_{16} 182–5°, b_{760} 300°, n^{20} 1.5745; *1-phenyl-1-anisyl-1-propane*, m. 53°; *1-phenyl-1-anisyl-2-propanone*, b_{25} 225°, d_{20} 1.159; *1-phenyl-1-anisyl ethane*, m. 75–6°. These alcs. were prepd. by the Grignard reaction and the amines by reduction of oximes in EtOH with Na. A. S. CARTER

Some molecular rearrangements in the course of the deamination of some aromatic amines. JEANNE LÉVY AND PAUL GALLAIS. Paris Univ. *Bull. soc. chim.* **43**, 862–8 (1928).—By slowly adding 3.5 g. of $NaNO_2$ (in soln.) to 11 g. of *2,2-diphenylethylamine-HCl* in 15 cc. of HOAc and 100 cc. of H_2O and heating for 1 hr. on the H_2O bath a brown oil was obtained which gave 7 g. of *stilbene* after Et_2O extn. and crystn. from EtOH. Reducing 20 g. of $Ph_2CMeCH{:}NOH$ with Na in EtOH gave 15 g. of *2,2-diphenyl-1-propylamine*, b_{22} 179–82°, d_{18} 1.027; *HCl deriv.* (I), m. 261–3°; *Bz deriv.* m. 82–3°; *Ac deriv.* m. 106–7°. I treated with $NaNO_2$ in HOAc forms *methylstilbene*, m. 82–3°, after distn. and crystn. from MeOH. Reduction of 20 g. of $Ph_2CEtCH{:}NOH$ by 30 g. of Na in 250 cc. of EtOH gave 12 g. of *2,2-diphenyl-1-butylamine*, b_{24} 125°, d_{20} 1.20; *HCl deriv.* (II) m. 252°; *Ac deriv.* m. 114°; *Bz deriv.*, m. 144–5°. When treated with $NaNO_2$, II gave *ethylstilbene*, b. 300–5°, which was identified by oxidation to PhAc. Failure to isolate intermediate alcs. in these reactions leads L. and G. to believe that $Ph_2CRCH_2N{\cdot}NOH$ forms $Ph_2CRCH<$ with simultaneous rearrangement to $PhCR{\cdot}CHPh$ and no intermediate Ph_2CRCH_2OH. A. S. CARTER

Some abnormal reactions of organomagnesium halides. HENRY GILMAN, J. E. KIRBY, R. E. FOTHERGILL AND S. A. HARRIS. Ia. State Col., Ames. *Proc. Iowa Acad. Sci.* **34**, 221–2(1927).—Nitro and nitroso groups react with methylmagnesium halides (and other RMgX compds.) to give CH_4 and some C_2H_6. The gases so evolved make it necessary to correct for the ordinary detn. of active H_2 by means of the Zerevitinov method. Accordingly the new hydroxy structure proposed for *o*-nitrobenzaldehyde finds no support on the basis of gas evolved when treated with alkylmagnesium halides. Benzylmagnesium halides, and related RMgX compds. like α-$C_{10}H_7CH_2MgCl$ (where the —MgX group is attached to a C that is attached in turn to an unsatd. C) have been found to give rearrangement products with new compds. like $ClCO_2Et$ and ethylene oxide. In some cases (with $PhCH_2MgCl$) rearrangement takes place to the *p*-position. A study is in progress of the mechanism of such rearrangements. In connection with the proof of the non-addn. of RMgX compds. to an ethylenic linkage, it has been shown that $PhCH{:}CHCOCl$ when treated with Mg gives largely a Grignard reagent which

when treated with CO_2 gives methylatropic acid. The 3 other cases in the literature that have been offered as apparent proofs for the addn. of RMgX compds. to an ethylenic linkage are also being investigated. W. G. GAESSLER

Action of diazo salts on aromatic sulfonamides. II. The mechanism of the reaction and the constitution of the diazosulfonamides. ARTHUR KEY AND PAVITRA KUMAR DUTT. Univ. of Leeds. *J. Chem. Soc.* **1928**, 2035–40; cf. *C. A.* **16**, 915.—The object was to elucidate the mechanism of the reaction $RSO_2NH_2 + R'N_2X \longrightarrow RSO_2NHN{:}NR' \longrightarrow RSO_2H + R'N_3$. The reaction may be a case of true migration of the H atom from the N to the O, followed by fission into the 2 final products; this was tested by heating p-$MeC_6H_4SO_2NHN{:}NPh$ both by itself and in C_5H_5N at a temp. above its decompn. point. In the former case a minute quantity of the azoimide was obtained but none was formed in the latter expt. The reaction is plausibly explained by the action of HO ions on the H which is incipiently ionized because of the strong electron attraction exercised by some neighboring center; this may be formulated as follows:

$$\overset{+\text{O}^-}{\underset{+\text{O}^-}{\text{R.S}}}\text{.HN.N:NR}' \longrightarrow \text{RSO}_2\overset{-}{\text{N}}\text{.N:NR}' + \overset{+}{\text{H}}.$$

AcOH gives PhOH and p-$MeC_6H_4SO_2NH_2$. The *Me deriv.*, p-$MeC_6H_4SO_2N\cdot NNMePh$, m. 124–5° (decompn.); reduction with Na-Hg gives NH_3, p-$MeC_6H_4SO_2NH_2$, PhNHMe, $PhNMeNH_2$ and $(PhMeNN{:})_2$. The isomeric Me deriv. from p-$MeC_6H_4SO_2NHMe$ and PhN_2Cl forms a gum which could not be crystd. Reduction gives $PhNH_2$ and $PhNHNH_2$, thus indicating that it is not identical with the 1st deriv. The electronic interpretation is also applied to these reactions. C. J. WEST

Preparation of guaiacolsulfonic acid from p-dichlorobenzene. JOSEF S. TURSKI, A. PIOTROWSKI AND S. WINAWER. *Przemysl Chem.* **11**, 365–70(1927).—This prepn. was accomplished as follows, with corresponding yields: p-dichlorobenzene $\longrightarrow$ 2,5-dichloronitrobenzene, m. 53° (98%) $\longrightarrow$ p-chloro-o-nitroanisole, m. 97° (85%) $\longrightarrow$ m-chloro-o-anisidine, m. 80° (92%) $\longrightarrow$ *chloroguaiacol*, m. 37° (66%) $\longrightarrow$ *guaiacolsulfonic acid* (88%). This does not m. 270°, and chars at a higher temp. With $FeCl_3$ it gives a bluish green color which turns yellow on careful addn. of NH_4OH. $BaCl_2$ in presence of NH_4 gives no ppt. as does the p-compd. HNO_3 in aq. solns. gives a brick-red color without pptn. Its aq. soln. reduces $AgNO_3$. In general its properties are identical with those of *Heyden's acid* (*Chem. Zentr.* **1907**, II, 1467; D. R. P. 188,506). Chloroguaiacol and o- (not the p-) guaiacolsulfonic acid possess important medicinal properties. A. C. ZACHLIN

Halogen derivatives of o- and p-azophenol. LOUIS HUNTER AND RONALD S. BARNES. Univ. Coll. of North Wales. *J. Chem. Soc.* **1928**, 2051–8.—The following derivs. of *4,4'-dihydroxyazobenzene* were prepd. by the use of the chloramine method; the brominating agent was a mixt. of KBr and dichloramine-T in AcOH: *3-Cl*, red, m. 184° (*di-Ac deriv.*, orange, m. 160–1°; *di-Bz deriv.*, yellow, m. 158–9°); *3,3'-di-Cl*, rust-red, m. 195° (*di-Ac deriv.*, orange, m. 199°; *di-Bz deriv.*, bright yellow, m. 226°); *3,5,3'-tri-Cl*, yellow-brown, m. 172° (*di-Ac deriv.*, orange, m. 207–8°; *di-Bz deriv.*, yellow, m. 189°); *3,5,3',5'-tetra-Cl*, crystg. with 6 H_2O, yellow, m. 225°, or, anhyd., 240° (*di-Ac deriv.*, yellow, m. 240°; *di-Bz deriv.*, orange, m. 244°); *3-Br*, yellow, m. 153°, rapidly darkens in the light (*di-Ac* deriv., orange, m. 142°; *di-Bz deriv.*, yellow, m. 165–6°); *3,3-di-Br*, light brown, m. 175° (*di-Ac deriv.*, yellow-orange, m. 161°; *di-Bz deriv.*, pale yellow, m. 227°); *3,5,3'-tri-Br*, brown, m., 184° (*di-Ac deriv.*, light brown, m. 172°; *di-Bz deriv.*, yellow, m. 216°); the 3,5,3',5'-tetra-Br deriv. yields a yellow *di-Ac deriv.*, m. 240°, and an orange *di-Bz deriv.*, m. 265°; *3,3'-dichloro-5,5'-dibromo*, yellowish red, m. 262°. The action of ICl on p-azophenol gives quinhydrone-azine. *2,2'-Dihydroxyazobenzene derivs.: 5-Cl*, brown, m. 164° (*di-Ac deriv.*, orange, m. 117°; *di-Bz deriv.*, brown, m. 119°); *5,5'-di-Cl*, orange-yellow, m. 267° (*di-Ac deriv.*, orange-red, m. 199°; *di-Bz deriv.*, pale brown, m. 243°); reduction and acetylation give *4-chloro-2-acetamidophenyl acetate*, m. 170°; the 3,5,5'-tri-Cl deriv., m. 235°, gives a *di-Ac deriv.*, pale orange, m. 189°, and a *di-Bz deriv.*, yellow-brown, m. 247°; *3,5,3',5'-tetra-Cl deriv.*, orange-red, m. 246–7° (*di-Ac deriv.*, pink, m. 195°; *di-Bz deriv.*, yellowish brown, m. 186°); reduction gives *2,4-dichloro-6-aminophenol*, m. 109° (decompn.), isolated as the *HCl salt*; *5-Br*, brown, m. 154° (*di-Ac deriv.*, dark orange, m. 142°; *di-Bz deriv.*, light brown, m. 215°); *5,5'-di-Br*, orange-red, m. 249° (*di-Ac deriv.*, orange, m. 211°; *di-Bz deriv.*, pale brown, m. 202°); 3,5,3',5'-tetra-Br, m. 262° (*di-Ac deriv.*, brown, m. 210–1°; *di-Bz deriv.*, orange, m. 214°); *5-I deriv.*, brown, m. 149–50° (*di-Ac deriv.*, brown, m. 138°; *di-Bz deriv.*, pale brown, m. 159°); *5,5'-di-I*, brown, m. 153° (*di-Ac deriv.*, dark brown, m. 145°; *di-Bz deriv.*, pale brown, m. 147°); reduction gives *p-iodo-o-aminophenol*, m. 139° (*HCl salt*); *3,5,3',5'-tetra-I*, brown, m. 98–9° (di-Bz

deriv., gray-brown, m. 241°); reduction gives *2,4-diiodo-6-aminophenol*, m. 120° (*HCl salt*). C. J. West

Preparation of some halogenoaminophenols. I. Mixed tetrahalogen derivatives of *o*-azophenol. II. Halogen derivatives of *p*-hydroxyazobenzene. Louis Hunter and Ronald Sidney Barnes. Univ. Coll. of North Wales. *J. Chem. Soc.* **1928**, 2058-67.—*5,5'-Dichloro-3,3'-dibromo-2,2'-dihydroxyazobenzene* (I) prepd. by chlorination and then bromination of *o*-azophenol, orange-red, m. 259° (decompn.); *di-Ac deriv.*, pale orange, m. 203°; *di-Bz deriv.*, orange, m. 212°; *3,3'-dichloro-5,5'-dibromo deriv.* (II), orange-red, m. 263°; *di-Ac deriv.*, orange, m. 199°; *di-Bz deriv.*, orange, m. 201°; *5,5'-dichloro-3,3'-diiodo deriv.* (III), orange-yellow, m. 272° (decompn.); *di-Ac deriv.*, orange, m. 205°; *di-Bz deriv.*, light brown, m. 254°; *5,5'-dibromo-3,3'-diiodo deriv.* (IV), light brown, m. 255° (decompn.) (83% yield); *di-Ac deriv.*, pale orange, m. 186°; *di-Bz deriv.*, pale brown, m. 252°; *3,3'-dibromo-5,5'-diiodo deriv.* (V), orange-red, m. 256°; *di-Ac deriv.*, golden, m. 217°; *di-Bz deriv.*, orange-red, m. 215°; the 3,3'-dichloro-5,5'-diiodo deriv. was obtained only as a dark brown amorphous powder. Reduction of I with $SnCl_2$ and HCl yields *4-chloro-6-bromo-2-aminophenol*, m. 89-90°; HCl salt; the *acetate* of the *2-Ac deriv.* m. 130°; the *benzoate* of the *2-Bz deriv.* m. 180.5°. Reduction of II gives *6-chloro-4-bromo-2-aminophenol*, m. 93°; *HCl salt;* the *acetate* of the *2-Ac deriv.* m. 137°; the *benzoate* of the *2-Bz deriv.* m. 182°. III gives *4-chloro-6-iodo-2-aminophenol*, charring about 90°; *HCl salt;* the *acetate* of the *2-Ac deriv.* m 169°. IV gives *4-bromo-6-iodo-2-aminophenol*, decomps. before melting; *HCl salt;* the *acetate* of the *2-Ac deriv.* m. 190°; the *benzoate* of the *2-Bz deriv.* m. 185°. V gives *6-bromo-4-iodo-2-aminophenol*, m. 90°; *HCl salt; acetate* of *2-Ac deriv.*, m. 196°; *benzoate* of the *2-Bz deriv.*, m. 194-5°. Since iodo-*p*-azophenols could not be prepd., I-substituted p-$H_2NC_6H_4OH$ were obtained by reducing the I derivs. of p-$HOC_6H_4N_2Ph$, which are readily accessible. o-BrC_6H_4OH and PhN_2X in strongly alk. soln. give 90% of *3-bromo-4-hydroxyazobenzene*, yellow, m. 80° (*HCl salt*, purple-brown, m. 159°; *Ac deriv.*, yellow-brown, m. 98°; *Bz deriv.*, brown, m. 113°). *3-I deriv.*, yellow, m. 77 8° (85% yield) (*HCl salt*, blue-black, m. 172° (decompn.); *Ac deriv.*, orange, m. 103-4°; *Bz deriv.*, pale orange, m. 105°). 3,4-$Cl(HO)C_6H_3N_2Ph$ on bromination with acetochloramide and KBr or 5,4-$Br(HO)C_6H_3N_2Ph$ on chlorination with dichloramine-T gives *3-chloro-5-bromo-4-hydroxyazobenzene*, orange, m. 125.5° (*Ac deriv.*, orange-brown, m. 133.5°; *Bz deriv.*, orange, m. 118.5°); reduction and acetylation give *2-chloro-6-bromo-4-acetamidophenyl acetate*, m. 168.5°; *benzoate* of the *4-Bz deriv.*, m. 111 2°. *3-Chloro-5-iodo-4-hydroxyazobenzene*, brown, m. 110°, *Ac deriv.*, orange-red, m. 124°, *Bz deriv.*, orange, m. 115°. Reduction gives *2-chloro 6-iodo-4-aminophenol*, m. 169° (decompn.); *HCl salt; acetate* of the *4-Ac deriv.*, m. 155°; *benzoate* of the *4-Bz deriv.*, m. 157°. *3-Bromo-5-iodo-4-hydroxyazobenzene*, orange-brown, m. 128.5°; *Ac deriv.*, orange, m. 127-8°; *Bz deriv.*, brown, m. 85°; reduction gives *2-bromo-6-iodo-4-aminophenol*, m. 185°; *HCl salt; acetate* of the *4-Ac deriv.*, m. 186°; *benzoate* of the *4-Bz deriv.*, m. 148°. 3,4-$I(HO)C_6H_3N_2Ph$ and ICl give the *3,5-diiodo deriv.*, brown, m. 128-9°, *Ac deriv.*, orange-brown, m. 162°; *Bz deriv.*, yellow, m. 137-9°; reduction and acetylation gives *3,5-diiodo-4-acetamidophenyl acetate*, m. 209°. C. J. West

Urea derivatives. St. Weil and T. Zyngier(owna). *Roczniki Chem.* **8**, 177-82 (1928); cf. *C. A.* **22**, 4202.—The following compds. were obtained by heating urea with the corresponding amine to 130 2°: *o-carbethoxyphenylurea*, begins to turn gray 336-7°, m. 342-3° (decompn.), sol. in org. solvents, insol. in water. *Pentamethyleneurea* of the same m. p. as Cahour's compd. (*Ann. chim.* [3] **38**, 84.) *Dicarbamidopiperazine* $C_4H_8N_2(CONH_2)_2$, m. 290°, sol. in alc. and water. *Antipyrylurea*, m. 245°, identical with Knorr's compd. (*Ann.* **293**, 65). *p-Carbethoxyphenylantipyrylurea*, from p-$NH_2C_6H_4CO_2Et$ and antipyrylurea or from aminoantipyrine and $NH_2CONHC_6H_4CO_2Et$ at 180°. Mary Jacobsen

The position occupied by the acetomercuric groups in anilines having in the nucleus a halogen group or a hydrocarbon residue. III. L. Vecchiotti. R. Univ. Bologna. *Gazz. chim. ital.* **58**, 231-9(1928); cf. *C. A.* **22**, 2555.—A new method of prepn. of p-$BrC_6H_4NH_2$ (I) is described. Br (5 g.) added dropwise to PhNHAc (27 g.) in 50% AcOH (160 cc.) cooled, dild. with water, filtered, the residue (p-BrC_6H_4NHAc) washed, dried, crystd. from EtOH, refluxed 3 hrs. with HCl (calcd. quantity) in abs. EtOH, cooled, the ppt. treated in water with excess 50% KOH and the ppt. crystd. from EtOH yields pure I. EtOH (200 cc. contg. a few cc. of AcOH) added to $Hg(OAc)_2$ in water (100 cc.), p-$BrC_6H_4NH_2$ (18 g.) in EtOH (100 cc.) added, let stand 48 hrs. with frequent agitation, the ppt. dissolved in NH_4OH contg. NH_4OAc, filtered, and repptd. by neutralizing with dil. AcOH, yields *2-acetatomercuri-p-bromoaniline* (II), m. 194°. An intimate mixt. of II (5 g.) and 50% KOH (25 cc.) let stand 24 hrs., dild. with water,

filtered, and the ppt. recrystd. from EtOH, yields *2-hydroxymercurio-p-bromoaniline*, m. 180°. Boiling satd. alc. KBr (1.19 g.) added to **II** (4.30 g.) in a min. of boiling EtOH ppts. on cooling *2-bromomercuri-p-bromoaniline* decomps. without fusion at 194°. Satd. alc. $Na_2S_2O_3$ (calcd. quantity) added to **II** (5 g.) in a min. of EtOH slowly ppts. *o,o'-mercuri-bis-p-bromoaniline*, decomps. 220°. **II** (6 g.) let stand 6 days with excess Ac_2O and the ppt. recrystd. from EtOH yields the *Ac deriv.* (**III**) of **II**, $C_{10}H_{10}O_3$-NBrHg. Br (3 g.) in glacial AcOH added with agitation to **III** (6 g.) in glacial AcOH, water added until pptn. is complete, and the ppt. recrystd. repeatedly from EtOH yields 2,4-dibromoacetanilide, m. 146° (cf. *Ber.* **7**, 348), which establishes the constitution of **II**. A survey of all Hg derivs. of $PhNH_2$ in which the H of the nucleus in *p*-position is replaced by a hydrocarbon residue or by a halogen or by HgOAc group shows in conformity to the rule of Pesci (*Gazz. chim. ital.* **48**, ii, 78 (1918); **51**, ii, 208 (1921)) that when an aromatic substance in which the *p*-position is already occupied is mercurated, the HgOAc group always enters the *o*-position. Anilines which have their *p*-nuclear H replaced by a hydrocarbon residue or by a halogen form in most cases only a single monomercurated deriv. (p-$O_2NC_6H_4NH_2$ is an exception). In anilines in which the *p*-nuclear H is replaced by a hydrocarbon residue or by a halogen group, the HgOAc group always enters, as in all similar cases in aromatic compds., the *o*-position with respect to the NH_2 group. When 2 HgOAc groups enter $PhNH_2$, one enters the *p*- and the other the *o*-position with respect to the NH_2 group C. C. D.

Action of mercuric acetate on *o*-bromoaniline. L. VECCHIOTTI. Univ. di Bologna. *Gazz chim. ital.* **58**, 239–44 (1928).—The expts complete work on the action of $Hg(OAc)_2$ on anilines with a halogen in *o*-position to NH_2 (cf. V. and Michetti, *C. A.* **21**, 395). $Hg(OAc)_2$ (32 g.) in water (100 cc) and EtOH (200 cc.) acidified slightly with AcOH, o-$BrC_6H_4NH_2$ (17 g) added, let stand 48 hrs., filtered, the ppt. washed, suspended in water, dissolved in NH_4OH contg. NH_4OAc, filtered, the filtrate neutralized with AcOH and the ppt again purified 3 times in the same way, yields *4-acetatomercuri-2-bromoaniline* (**I**), m. 152–3° **I** (5 g.) digested 2 days in excess 50% KOH, a large quantity of water added, filtered, the residue washed repeatedly, and dried *in vacuo* over $CaCl_2$, yields the *hydroxymercuri deriv.*, $C_6H_6ONBrHg$, m. 253–4°. Boiling satd. alc. NaBr (1.03 g.) added to boiling satd. alc **I** (4.30 g.), boiled a few min. and cooled, ppts. the *bromomercuri compd.*, $C_6H_5NBr_2Hg$, m. 213–4°. **I** (approx. 4 g) digested 4 hrs. on a water bath with a slight excess of Ac_2O and then 2 hrs. at room temp., filtered, washed with water until neutral, dried *in vacuo* over NaOH, and recrystd. from glacial AcOH, yields the *Ac deriv.* (**II**) of **I**, $C_{10}H_{10}O_3NBrHg$, m. 220 1°. **I** (approx. 3 g.) digested 48 hrs. with excess 50% aq. $Na_2S_2O_3$, water added, and filtered, yields *4,4'-mercuribis-o-bromoaniline*, $[Br(H_2N)C_6H_3]_2Hg$, m. 125°. NaBr (1 mol. per mol. of **II**) in EtOH and then Br (2.03 g.) in glacial AcOH added to **II** (4 g.) in glacial AcOH, let stand 4 hrs., a large quantity of water added, salted out with KNO_3 and the ppt recrystd. from EtOH, yields $2,4$-$Br_2C_6H_3NHAc$, m. 146° (cf. *Ber* **7**, 348), which establishes the constitution of **I**. C. C. D.

Condensation of 4-chloro-3-nitrophenylarsonic acid with some amino substances and particularly with ethylenediamine and piperazine. Reduction of the nitro products to amines. ERNEST FOURNEAU AND A. FUNKE. Pasteur Inst. *Bull. soc. chim.* **43**, 889 95 (1928) -Heating 10 g. of *ethylenediamine* (**I**) and 5 g. of *4-chloro-3-nitrophenylarsonic acid* (**II**) for 1 5 hrs. at 135–40° in the presence of anhyd. NaOAc gave a yellow mass from which 95% of *4-[2-aminoethylamino]-3-nitrophenylarsonic acid* (**III**), $H_2NCH_2CH_2NHC_6H_3(NO_2)AsO_3H_2$, was obtained by dissolving in dil. Na_2CO_3 and pptg. with an equiv. quantity of HCl. **III** was suspended in H_2O and treated with 30% excess Ac_2O, filtered hot and upon cooling 85% of the *Ac deriv.* (**IV**) was pptd. **IV** was reduced by dissolving 11.5 g. in a mixt. of 15 cc. of 10 *N* NaOH and 10 cc. of H_2O and pouring this soln. alternately with 35 cc. of 10 *N* NaOH into 30 g. of H_2O contg. 65 g. of $FeSO_4.7H_2O$. The temp. was held below 50° for 0.5 hr., then cooled to 3°, pptg. most of the Na_2SO_4, filtered and neutralized, pptg. 50% of the *aminophenyl deriv.* of **III**. In the initial condensation, using a 50% aq. soln. of **I**, 80% of *ethylenedi[4-amino-3-nitrophenylarsonic acid]* (**V**), $(CH_2NHC_6H_3(NO_2)AsO_3H_2)_2$, resulted instead of **III**. Reduction of **V** gave 20–5% of the *aminophenyl deriv.* One mol. of **II** and 2.5 mols. of *piperazine-2HCl* in 1.2 l. of 10 *N* NaOH heated for 0.5 hr. and pptd. with HCl gave 65% of *4-piperazine-3-nitrophenylarsonic acid*, $HN:(CH_2CH_2):NC_6H_3(NO_2)AsO_3H_2$. With 5 g. of **II**, 5 g. of piperazine.$6H_2O$ and 2 g. of NaOAc, heating at 110° for 2 hrs., dissolving in Na_2CO_3 and pptg. with HCl gave *piperazinedi-[3-nitrophenylarsonic acid]*, $H_2O_3AsC_6H_3(NO_2)N:(CH_2CH_2):NC_6H_3(NO_2)AsO_3H_2$. Condensation of **II** with Et *p*-aminobenzoate gave *4-[p-carbethoxyphenylamino]-3-nitrophenylarsonic acid*, $EtO_2CC_6H_4NHC_6H_3(NO_2)AsO_3H_2$, which was reduced by $FeSO_4$ to the *aminophenyl deriv.* These compds. were tested on *trypanosomiasis*. A. S. CARTER

Triphenylstibine sulfide. O. Yu. Magidson and B. Süsskind. *Trans. Sci. Chem.-Pharm. Inst. (Moscow)* **6**, 21–8(1923).—Good yields of triphenylstibine sulfide are obtained by a modification of Michaelis and Reese's method, the time of reaction being shortened, and half the usual quantity of Na employed. B. C. A.

Extractibility of phenols from their alkaline solutions by ether. G. Vavon and N. Zaharia. *Compt. rend.* **187**, 346–8(1928).—Phenols may be partially extd. from their alk. solns. by means of Et_2O. The proportion extd. depends on the structure of the phenol. With the introduction of radicals into PhOH, the proportion extd. increases, and is greater for *o*-substituted phenols than for the *m*- or *p*-isomers. The cause for this extractibility lies in a more or less profound hydrolysis of the Na phenolate, but it depends besides on the soly. of the phenol in the phenolate soln. and in Et_2O. The proportions extd. for a no. of phenols varied from 7.5 to 97.7%. For these detns. 0.01 mol. of the phenol and 0.01 mol. NaOH in 10 cc. soln. were extd. with 20 cc. Et_2O at 15° for 10 min. With thymol, the use of different solvents gave the following % extd.: Et_2O 88, benzene 38, CCl_4 25, petroleum ether 22. In the *purification of phenols*, it is recommended that petroleum ether be used for the extn. and that an excess of alkali be employed. In treating a mixt. of 2 phenols with insufficient NaOH to give the phenolates, and extg. with Et_2O, there occurs a fractionation, the less extractible phenol remaining mainly in the alk. soln. This furnishes a method therefore for the *sepn. of* some *phenols.* Frederick C. Hahn

Sodium and potassium phenoxides. A. N. Meldrum and M. M. Patel. *J. Indian Chem. Soc.* **5**, 91–4(1928).—These compds. may be obtained in a state of purity by pptn. of solns. of the phenol in 20% alkali hydroxide with concd. alkali soln. (100–200 g. in 100 g. of water). In this way the following are prepd.: Na phenoxide, m. 59–60°; K phenoxide, m. 103–4°; Na *o*-, *m*-, and *p*-cresoxides, m. below 0°, and 92–4°, and 123–5°, resp.; K *o*- cresoxide, cryst., *m*-, and *p*-, m. about 36° and 92°, resp.; Na *m*-xylyloxide, m. 41–3°; K *m*-xylyloxide, liquid; Na *p*-xylyloxide, m. 83°; K *p*-xylyloxide, m. 35°; Na guaiacoxide, m. 120°; K guaiacoxide, m. 168°; Na eugenoxide, m. 115°; K eugenoxide, m. 128°; Na α- and β-naphthoxides, m. 44–5° and 120°, resp.; K α-naphthoxide, liquid; K β-naphthoxide, m. 38–40°. B. C. A.

Aluminum powder as a synthetic reagent. A. C. Ray and S. Dutt. *J. Indian Chem. Soc.* **5**, 103–10(1928); cf. J. N. Ray (*C. A.* **15**, 1133).—Al powder may be activated for synthetic purposes by heating it in a current of dry H at 500°. The activation is apparently not due to the formation of a hydride or to the removal of a film of Al_2O_3, since that oxide is not reduced under the conditions employed. It is suggested that a film of a suboxide is removed in the activation. Dry distn. of phenol with the activated Al affords benzene and Ph_2; nitrophenols yield aminophenols, NH_3, and benzene. The powder may also be used in typical Ullmann, Freidel-Crafts, and Reformatsky reactions. When used in the reduction of a suspension of $PhNO_2$ in aq. NH_4Cl, it affords PhNHOH at 0° and aniline at the ordinary temp. Under the latter conditions it may be employed in the reduction of Ph_2CO to benzohydrol and in the reduction of azo dyes. B. C. A.

Azopicric acid. K. Elbs and O. H. Schaaf. Univ. Giessen. *J. prakt. Chem.* **120**, 1–35(1928).—Reduction of m-$O_2NC_6H_4OMe$ with Zn and NaOH gives 80% of *m-azoanisole*, orange-yellow, m. 76–7°; nitration with KNO_3 and concd. H_2SO_4 gives the *2,4,6,2',4',6'-hexanitro deriv.*, dark reddish yellow, m. 126°, from AcOH, or red to brownish red, m. 127°, from MeOH. Boiling with H_2O for 15 min. gives *azopicric acid* (I), m. 238°; this behaves as a dibasic acid, but esters could not be obtained and ethers could be prepd. only indirectly; nitration of *m*-azophenetole gives the corresponding *5,5'-di-EtO deriv.*, red to reddish yellow, m. 138–9°. Reduction with NaSH gives, instead of azopicramic acid, *pentanitrodihydroxyphenylphentriazole*, brown amorphous powder, m. 176–80° (decompn.); the NO_2 groups may be catalytically reduced. I and NaOH give a brown smear, which was not investigated; K_2CO_3 gives *trishydroxaminotrihydroxybenzene*, pale yellow, m. 166°, which is easily oxidized to trinitrophloroglucinol; excess of K_2CO_3 gives the K salt of the phenol, the intermediate *bishydroxamino deriv.*, m. 166° (decompn.), and the *monohydroxamino deriv.*, m. 146–8° (decompn.). The absorption curves of I and picric acid are compared. The explosive power of I is somewhat greater than that of picric acid; the explosion proceeds according to the equation: $[(O_2N)_3C_6H(OH)N:]_2 = 12CO + 2H_2O + 8N$. C. J. West

Bi-singlet and the semipolar double bond. H. D. K. Drew. Birmingham Univ. *Chemistry and Industry* **47**, 949–51(1928).—A theoretical paper in which is discussed the formulation of salts of phenoxtellurine and the corresponding Se and S derivs. From the speculation concerning them, D. raises the questions: Can analogous compds., having markedly different properties, be represented adequately by the same type of

electronic formula; is there, or is there not, any real difference in fact between the semipolar double bond (and, what is at all events superficially equiv. to it, the co-ordinate linking of Sidgwick) and the bi-singlet linking, *i. e.*, 2 singlet linkings uniting a pair of atoms? C. J. West

Quadrivalency of selenium. I. 4-Carboxydiphenyl and *p*-carboxyphenyl methyl selenoxides. Wilson R. Gaythwaite, Joseph Kenyon and Henry Phillips. Battersea Polytechnic. *J. Chem. Soc.* **1928**, 2280–7.—The resolution of 4-$H_2NC_6H_4$(4-MeC_6H_4)SO and (4-$HO_2CC_6H_4$)MeSO into their optically active forms (*C. A.* **20**, 3448) showed that the double bond between S and O in these compds. is unsym. and can therefore be considered to be a semipolar double bond. Attempts have now been made to resolve I, II and III (below) but they were unsuccessful; this result, together with the chem. evidence, shows that the linking between the Se and O atoms of a selenoxide may be partly polar in character but at the same time may tend to utilize or render inert the remaining combining capacity of the Se atom in a manner which suggests that the linking may not be an unsym. semipolar double bond. *p*-$MeC_6H_4SO_2Ph$ (116 g.) and 40 g. Se, heated until SO_2 is evolved and after 2–3 hrs. distd., give 35 g. *phenyl p-tolyl selenide*, pale yellow, b_{20} 175–8°; *dibromide*, orange-red, m. 149–50°; with NaOH there results the *selenoxide* (I), m. 131–3°; this also results from the selenide and $KMnO_4$. Attempts to resolve I by means of *d*-camphorsulfonic acid failed. Prolonged oxidation of the selenide with $KMnO_4$ gives *4-carboxydiphenyl selenoxide* (II), m. 253–5° (decompn.); reduction with Zn and AcOH gives the *selenide*, pale yellow, m. 182–4°, whose *dibromide*, yellow, m. 208–10°. II yields a *brucine salt*, m. 130° (decompn.); *l-menthylamine salt*, m. 220–2° (decompn.); $[\alpha]_{5461}$ —16.4° (EtOH, *c* 0.8145); *d-α-phenylethylamine salt*, m. 194 5° (decompn.), $[\alpha]_{5461}$ —12.7° (C_5H_5N, *c* 1.139); in no instance was any resolution observed. *p*-$HO_2CC_6H_4N_2Cl$ and KSeCN in alk. soln., after boiling with 2 *N* NaOH, give *4,4'-dicarboxydiphenyl diselenide*, pale yellow, m. 297°; reduction with Zn in aq. NaOH, followed by Me_2SO_4, gives *p-carboxyphenyl Me selenide*, pale yellow, m. 174°; *dibromide*, orange red, m. 198–9°; the *selenoxide* (III), by oxidation of the selenide with H_2O_2 or the action of KOH on the dibromide, m. 183–4° (decompn.); *brucine salt*, m. 105–10°, on crystn. gives a mixt. of the salt of the selenide and III. **II. The simple halogen derivatives and the dihydroxide of 4-acetamidodiphenyl selenide.** *Ibid* 2287–93.—The primary object of this investigation was to prep. and attempt the resolution of 4-aminodiphenyl selenoxide; however, this proved unstable in the presence of acids. *4-Aminodiphenyl selenide*, m. 93–4°, results by heating a mixt. of benzeneselenonic acid and $PhNH_2$ at 110–5° for 6 hrs.; *HCl salt*, m. 159°; *Ac deriv.* (I), m. 169–70°, decomps. when heated with mineral acids. Oxidation of 5.8 g. I in AcOH with 4 cc. H_2O_2 gives 5.7 g. of the *dihydroxide*, $AcNHC_6H_4SePh(OH)_2$ (II), m. 147–8° (decompn.); Zn and AcOH reduces it to I; warming with 0.5 *N* HCl for 1 hr. also gives I, which is also formed by the action of heat on II. Heated at 20 mm. and 120–30°, there results *4-acetamidodiphenyl selenoxide* (III), m. 144–6°; crystn. from aq. EtOH gives II. III and EtOH-NaOH give *4-aminodiphenyl selenoxide*, m. 188–9°, also obtained from the selenide and H_2O_2. II and concd. HCl in AcOH give *4-acetamidodiphenyl selenide dichloride*, m. 131–2°; the same product is not obtained from I and Cl. The *dibromide*, red, m. 135–6°, results from I and Br in AcOH or II and HBr; Zn in AcOH gives I; NaOH gives II; heating at the m. p. for 0.5 hrs. causes the evolution of HBr and the formation of the *compd.*, $C_{14}H_{11}ONBr_2Se$, m. 167°, possibly 3,5-dibromo-4-acetamidodiphenyl selenide. I and I give the *diiodide*, chocolate-brown, m. 144–5° (decompn.); this also results from II and HI or from the dibromide and KI; heated at its m. p. for 1 hr., I is evolved and I formed, a change which takes palce at room temp. in 10 days. **III. The instability of the compounds of quadrivalent selenium derived from phenyl methyl and phenyl ethyl selenides and phenyl- and *p*-tolylselenoglycolic acids.** Owen J. Kempster Edwards, W. R. Gaythwaite, J. Kenyon and H. Phillips. *Ibid* 2293–303.—On account of their instability, much difficulty has been experienced in the prepn. of selenoxides contg. an alkyl group attached to the Se atom; such selenoxides have been found to decomp. on heating mainly as indicated by the equation $RSeOCH_2R = RSeH + RCH.O$ Sulfoxides behave similarly, and it has been suggested that these undergo an isomeric change by a process analogous to the keto-enol change as the initial step in the decompn. The following study was made to investigate whether such a change occurs in the Se compds. $PhMeSe(CH_2CO_2H)Br$, from PhMeSe and $BrCH_2CO_2H$, on heating at 110°, gives MeBr and $PhSeCH_2CO_2H$, b_{10} 197–8°, m. 36–7°. The reverse of this reaction could not be accomplished. Br in CCl_4 gives the *dibromide*, yellow, m. 126°; the soln. in 10 parts of hot glacial AcOH deposits PhSeBr on cooling. At its m. p. it decomps. mainly into PhSeBr and $BrCH_2CO_2H$. *p*-$MeC_6H_4SeMe(CH_2CO_2H)Br$ behaves similarly, giving *p*-$MeC_6H_4SeCH_2CO_2H$,

whose dibromide, m. 103–4°, on heating at its m. p. for a few min., gives $BrCH_2CO_2H$ and probably *p*-bromoselenotoluene, a reddish brown oil; the *dibromide*, red, m. 113–4° (decompn.). *Ph Me selenide dibromide*, yellow, m. 115–6° (decompn.); heated at 120–30° for 10 min. it gives MeBr and PhSeBr; with KI there results the *diiodide*, purple, m. 69–71°, if at 40°, or the *bromoiodide*, red, m. 85° (decompn.), if in the cold; the latter on heating at 100° gives PhSeBr and MeI; this mode of decompn. is not inconsistent with the view that such decompns. pass through a preliminary phase, which involves the loss of a proton by the Me group and causes this group to be less firmly attached to the Se atom. With Ag_2O in H_2O the dibromide gives a dihydroxide, a viscous oil which could not be entirely freed from H_2O without decompn.; heating at 100° and 15 mm. or 170° and 760 mm. gives PhMeS, Ph_2Se_2 and HCHO. *Ph Et selenide dibromide*, light red, m. 84°; heating at 130° for 10 min. gives PhSeBr and EtBr. PhEtSe and $BrCH_2CO_2H$ give $PhSe(CH_2CO_2H)$. The main course of the reaction of the decompn. of Ph_2SeBr_2 by heat is to give $PhSeC_6H_4Br$ and HBr. C. J. West

Organic sulfur compounds. IX. Preparation of aromatic thio ketones by the action of thioacetic acid on ketone chlorides. Action of copper-bronze on thiobenzophenone and its derivatives. A. Schönberg, O. Schütz and S. Nickel, with H. Krüll, W. Marschner and F. Kaplan. Techn. Hochschule Charlottenburg. *Ber.* **61B**, 1375–85(1928); cf. *C. A.* **22**, 587.—Numerous compds. of the $CSPh_2$ series can be obtained easily and in good yield from AcSH and aromatic ketone chlorides. $CSPh_2$ itself has for the 1st time been obtained perfectly pure by this method. The reaction $Ar_2CS \longrightarrow Ar_2C.CAr_2$, effected by Gattermann by heating the Ar_2CS with Cu-bronze at 200–20°, gives purer products when it is carried out in xylene. $CSPh_2$ reacts smoothly, $(p\text{-}MeOC_6H_4)_2CS$ (I), $(3,4\text{-}Me(EtO)C_6H_3)_2CS$ (II), *xanthione* (III) and *thioxanthione* (IV) less readily, while Michler's thio ketone (V) and *N-phenylthioacridone* (VI) are quite resistant. $CSPh_2$ (28 g. from 50 g. Ph_2CCl_2 slowly treated at 80° under pure dry CO_2 with 50 g. AcSH, then heated 3 hrs. at 90° and 4 hrs. at 100° and fractionated, first under a low and finally under a high vacuum), deep blue oil, $b_{0.05}$ 126–9°, seps. from petr. ether (4 g. in 20 cc.) in ice in blue needles, m. 51°, gives in Et_2O with $HgCl_2$ a compd. $Ph_2CS.HgCl_2$ or $[Ph_2CSHgCl]Cl$, reacts vigorously (under N) in Et_2O with PhMgBr, at once changing from blue to red. In the air the blue crystals quickly deliquesce and after long standing and frequent stirring change to a dirty gray-blue solid mass from which, by recrystn. from ligroin, can be obtained a well-crystd., S-contg., colorless substance, decompg. above 100° with formation of a blue color and forming in the cold colorless or faintly blue solns. which become deep blue on heating. *4,4'-Diphenylthiobenzophenone*, from $(p\text{-}PhC_6H_4)_2CCl_2$ and 3 mols. AcSH refluxed 14 hrs. in C_6H_6 under CO_2, green-blue, m. 228–9°. *4-Methoxy-4'-ethoxybenzophenone* (19 g. from 25 g. $p\text{-}MeOC_6H_4COCl$, PhOEt and $AlCl_3$ in CS_2), m. 112°, sol. in concd. H_2SO_4 with yellow color, converted into the dichloride by refluxing with $(COCl)_2$; *thio ketone*, dark blue, m. 94–6°, sol. in concd. H_2SO_4 with yellow, somewhat reddish color. *2,2'-Dimethoxythiobenzophenone*, dark blue, m. 121°, sol. in the ordinary solvents with blue, in liquid SO_2 with red color, gives in Et_2O with $HgCl_2$ deep red crystals. I (4.4 g. from 7.5 g. $(MeOC_6H_4)_2CO$ through the dichloride), deep blue, m. 114–5°. III (3.5 g. from 5 g. xanthone), m. 156°. IV, black needles with somewhat greenish surface luster, m. 168°, sol. in the usual solvents with green color, gives with $HgCl_2$ in Me_2CO red needles, dissolves in concd. H_2SO_4 with orange-red color. VI (62% from *N*-phenylacridone refluxed in C_6H_6 with P_2S_5), red, m. 227–8°. Boiled in xylene with Cu-bronze to disappearance of the blue color (45 min.), 3.3 g. $CSPh_2$ gives 2.1 g. $Ph_2C:CPh_2$; 0.5 g. I yields 0.4 g. $[(p\text{-}MeOC_6H_4)_2C:]_2$, m. 183°; $(p\text{-}EtOC_6H_4)_2CS$ and II behave in the same way; V is unchanged after 24 hrs. boiling; 0.5 g. III in 4–5 hrs. gives 0.35 g. *dixanthylene*, faintly yellowish, somewhat greenish needles; IV in 5 hrs. yields *dithioxanthylene* (VII), does not m. 340°. (Since this paper was written, the dissertation of Lorenz (*Breslau*, **1927**), describing pure IV, m. 176°, and VII, m. 365°, has come to hand; cf. also Arndt and Lorenz, *C. A.* **22**, 2563.) C. A. R.

Thiobenzophenone. H. Staudinger and H. Freudenberger. Eidgen. Techn. Hochschule Zürich u. Univ. Freiburg i. Br. *Ber.* **61B**, 1576–83(1928).—The results of this work, part of which was done in 1920 (cf. *C. A.* **15**, 518) with E. Senn and I. Siegwart, are published now because of the appearance of the paper of Schönberg, Schütz and Nickel (preceding abstr.). The colorless addn. product of Ph_2CS (I) and $Ph_2C:CO$ decomps. at its m. p. (180–1°) into its components which cannot be sepd. by fractional distn. and recombine on cooling, but if 1 mol. PhCH:NPh is added it reacts only with the $Ph_2C:CO$ to form a stable, high-boiling lactam and pure I, deep violet, m. 54–5°, can now be obtained by distn. in a high vacuum. A study of the Gattermann method of prepn. showed that even when the air is rigorously excluded it is not possible to obtain

a product contg. more than 30–50% Ph_2CS, as the Ph_2CCl_2 is partially converted into Ph_2CO by the alkali. By treating the Ph_2CCl_2 in alc. with the calcd. quantity of NaSH instead of Na_2S (the NaSH must be added to the Ph_2CCl_2 and not *vice versa*, as otherwise the I is reduced by the NaSH to $(Ph_2CHS)_2$ (II)) a deep blue oil can be obtained which contains about 75% I and yields almost pure I on fractional distn. and recrystn. from alc. The polymer, m. 146°, of I which Siegwart (*Diss. Zürich*, **1917**) believed he had obtained from Ph_2CCl_2 and K_2S in excess was really chiefly **II**, m. 152–3°, contaminated with a little S. Ph_2CO (20 g.) in 100 cc. 96% alc. treated cold for 2–3 hrs. with dry H_2S and HCl, then 20 hrs. with H_2S, gives 15 g. pure **I**, which by this method is made a very readily available compd. Pure **I** does not polymerize even after a yr. either of itself or on addn. of C_5H_5N, NMe_3 or PH_3 or treatment with HCl gas. With Na_2S or NaSH, even more readily with $(NH_4)_2S$, it is reduced in alc. to **II**. NaOEt likewise reduces it to **II** but with partial formation of Ph_2CO and other by-products. **II** is also obtained quant. from Ph_2CHSH and the calcd. quantity of **I**, from Ph_2CO and $(NH_4)_2S$, most conveniently from Ph_2CCl_2 and excess of NaSH; Al-Hg reduces it to Ph_2CHSH, which on heating decomps. into S and Ph_2CH_2. As already pointed out, the C:S group in **I** is far more reactive than the C·O group in Ph_2CO. **I** reacts very rapidly with $Ph_2C·CO$ in the cold and readily with aliphatic diazo compds. to form ethylene sulfides, with $PhNH_2$ and especially with $PhNHNH_2$, but does not condense with AcH, Me_2CO or AcOEt. At 160–70° it decomps. into $(Ph_2C:)_2$ and S. With HCl and concd. H_2SO_4 it forms brown addn. products hydrolyzed by H_2O. It readily undergoes autoxidation, yielding Ph_2CO, a little S and SO_2 and a trisulfide m. 124°. C. A. R.

The determination of gossypol structure. E. P. CLARK. *Oil and Fat Ind.* **5**, 273–7(1928).—The action of 40% NaOH at steam bath temp. on gossypol produces HCO_2H and a phenolic substance, called apogossypol, which is a colorless cryst. material having no definite m. p. It is sol. in org. solvents and dissolves freely in dil. alkali from which it is pptd. by CO_2. The alk. solns. darken at once and become purple, and even a few hrs.' exposure of the cryst. apogossypol causes it to change to a black powder. It readily forms colorless cryst. Ac and MeO derivs. and a study of these has shown that the formula for apogossypol is $C_{28}H_{30}O_6$. From a consideration of the formula for gossypol, $C_{30}H_{30}O_8$, it is seen that hot alkali removes 2 C:O groups and since HCO_2H alone is produced the C:O groups must be eliminated as HCO_2H and each mol. of gossypol should produce 1 mol. of apogossypol and 2 mols. of HCO_2H and the yield of these substances obtained corresponded to 97.5 and 95.3% of theory. The toxicity of apogossypol was found to be $^1/_3$ of that of gossypol and its action seems to be restricted to the development of acute toxic symptoms. The oxidation of gossypol in NaOH with $KMnO_4$ at 0° gave evidence of volatile fatty acids and, after steam distn., formic, acetic and isobutyric acids were found. Biol. expts. on rats showed that 0.05% of pure gossypol in food produced a retardation of the growth rate and 0.2% caused loss of wt. and death. E. SCHERUBEL

Dibenzyl ether as a cryoscopic solvent. GEORGE MACDONALD BENNETT AND GERVASE H. WILLIS. Univ. of Sheffield. *J. Chem. Soc.* **1928**, 2305–7.—$(PhCH_2)_2O$ b_{28} 184, b_{16} 170°, m. 3.60, $d_4^{10.5}$ (vac.) 1.0504, d_4^{20} (vac.) 1.0428; it often remained for hrs. in the supercooled state, but crystn. could always be induced by vigorous stirring at a temp. below —15°. The following values of the f. p. const. *K* were found: PhOEt, 62.6; $C_2H_4Br_2$, 61.8; $PhNMe_2$, 62.8; $C_{10}H_8$, 63.6; from the mean value, 62.7, the latent heat of fusion of $(PhCH_2)_2O$ is calcd. to be 24.4 cals. per g. A few f. p. observations were also made with BzOH, AcOH and $PhCH_2OH$ as solutes; the apparent mol. wts. in C_6H_6 and $(PhCH_2)_2O$ are: BzOH, 228–36, 147–77; AcOH, 115–22, 91.6–109; $PhCH_2OH$, 116–65, 135–40. C. J. WEST

Monoacetals of α-bromodibenzoylmethane. CHARLES DUFRAISSE AND ALFRED GILLET. *Bull. soc. chim.* **43**, 883–8(1928).—*α-Ethoxybenzalacetophenone* (17.5 g.) was dissolved in 360 g. of dry CS_2, cooled with ice-salt mixt. and to this was added 11.5 g. of Br in 30 g. of CS_2 followed immediately by 30 g. of KOAc in 250 cc. of abs. EtOH. After boiling, this was poured into H_2O, sepd., washed with $NaHCO_3$ soln. and distd. under diminished pressure, giving 78% of *α-bromo-α,α-diethoxy-benzylacetophenone* (**I**), $BzCHBrC(OEt)_2Ph$, m. 70°. Likewise the following were prepd.: *di-MeO deriv.*, m. 91–2°, and *di-PrO deriv.*, m. 83–4°. These acetals were also prepd. according to the following example: 1 g. of *α-bromo-α-ethoxybenzalacetophenone* (**II**) and 0.5 g. of Na in 7 g. of abs. EtOH were sealed and held at 0° for 36 hrs., giving 95% of **I** after distn. By this method, 50% of the *α-methoxy-α-ethoxy mixed acetal*, m. 89–90°, was prepd. using MeOH and **II**. A. S. CARTER

The Nierenstein reaction. M. NIERENSTEIN. Univ. Bristol. *Nature* **122**, 313(1928).—Bradley and Robinson (*C. A.* **22**, 3412) have failed to get satisfactory yields

of —$PhCOCH_2Cl$ because they have modified M.'s original method. Cf. *C. A.* **10,** 44.
R. J. HAVIGHURST

Isoeugenol. SCHIMMEL AND CO. *Schimmel and Co., Ann. Rept.* **1927,** 138; *Chem. Zentr.* 1927, II, 1472.—An isoeugenol was obtained in large water-white crystals, m. 32°, and stable at room temp. in the absence of air. The two modifications can be explained on the basis of *cis-trans*-isomerism. The liquid form is a mixt. of the malenoid and fumaroid forms.
J. S. REICHERT

Nitration of piperonal. JOHN B. EKELEY AND MARGARET S. KLEMME. Univ. of Colorado. *J. Am. Chem. Soc.* **50,** 2711–5(1928).—Repetition of earlier expts. (*C. A.* **16,** 3313) confirms the existence, in com. Kahlbaum nitropiperonal, of an *isomer* (I), m. 143°; this was found both by means of the previously reported derivs. and by fractional crystn. of the K. product. In an attempt to prep. I, piperonal was nitrated under varying conditions of temp. and of HNO_3 concn. with and without H_2SO_4 in the presence and absence of catalytic agents and in the presence and absence of sunlight. Besides the *o*-nitropiperonal, m. 98.5°, mono- and dinitromethylenecatechols, nitropiperonylic acid and an isomeric *mononitromethylenecatechol* (II), yellow, m. 70°, are obtained. Increase in temp. in general causes an increase in oxidation products. Beyond a HNO_3 of d. 1.38, increase in acid concn. also causes an increase in oxidation products. The presence of nitrosulfonic acid causes a decrease in oxidation and an increase in nitration; the presence of glacial AcOH causes an increase in the nitration, but the best yield of nitropiperonal was obtained with HNO_3 of d. 1.38 at 45°; no trace of I was found. The isomeric I is probably formed as an intermediate product in the expts. using fuming HNO_3, as indicated by the isolation of II from the reaction mixt. Yields are given for 21 nitration expts.
C. J. WEST

The identity of volemitol and α-sedoheptitol. F. B. LAFORGE AND C. S. HUDSON. *J. Biol. Chem.* **79,** 1–3(1928).—The data concerning volemitol and its derivs. recorded in several standard compilations contain so many erroneous statements that it was thought advisable to give briefly a correct record of the exptl. data that have been published together with the evidence leading to the conclusion that volemitol and α-sedoheptitol are identical.
A. P. LOTHROP

Action of diazomethane on piperonal. ERICH MOSETTIG. Univ. Wien. *Ber.* **61B,** 1391–5(1928); cf. Arndt, *C. A.* **22,** 2930.—In connection with A.'s observations on the anomalous behavior of certain aldehydes with CH_2N_2, M. reports some astonishing results he obtained in an attempt to prep. acetopiperone (I) from piperonal (II) and CH_2N_2. When solid II at about —15° is treated with excess of CH_2N_2 in Et_2O to which MeOH has been added to accelerate the reaction there is obtained an almost colorless oil boiling *in vacuo* quite const. and without the least decompn. On working up, this yields about 6% I, 20% piperonylacetone (III) and, as chief product, an alkali- and acid-insol. mobile oil (IV) of intense and pleasant odor, which distils *in vacuo* without decompn., shows neither ketone nor aldehyde properties, becomes faintly yellow in the air only after several weeks, has a simple mol. wt and the compn. $C_{10}H_{10}O_3$, *i. e.*, IV is isomeric with III and two CH_2 groups have reacted with the II. Sepn. of the 3 products is difficult. The vacuum-distd. crude product is freed of III by shaking in Et_2O with aq. $NaHSO_3$, then of thick substances very difficultly sol in petr. ether by digesting with that solvent; after distg., most of the I crysts. out (the rest cannot be removed as the semicarbazone because of the sensitivity of the IV to AcOH (or $H_2NCONHNH_2$)); another fractional distn. now gives a IV of const. b. p. and the calcd compn. but still contg. detectable quantities of I. At present only conjectures can be made as to the structure of IV; the absence of MeO precludes its being a 3,4-methylenedioxy-α-methoxystyrene; its pleasant odor might be taken as an indication of an oxide structure (which would also be supported by A.'s results), that of an α-[3,4-methylenedioxyphenyl]propane α,γ-oxide being the most probable (the non-identity of IV with safrole or isosafrole oxide was proved by direct comparison). All attempts to establish the constitution of IV by various reactions (which, however, have been made only on small quantities because of lack of material) have yielded non-crystallizable oily and resinous products. Preliminary expts. with *o*- and *m*-veratraldehyde indicate that these also give other products besides the ketone with CH_2N_2. The addn. of MeOH and the form in which the aldehyde is used (solid or in soln.) has a great influence on the course of the reaction; *e. g.*, II in Et_2O with CH_2N_2 also in Et_2O gives I as chief product with only a vanishingly small quantity of IV.
C. A. R.

Reaction between the binary system, magnesium + magnesium iodide, and aromatic acids and acid derivatives. M. GOMBERG AND W. E. BACHMANN. Univ. of Michigan. *J. Am. Chem. Soc.* **50,** 2762–9(1928).—Org. acids in soln. in Et_2O and C_6H_6 react vigorously with the binary system Mg + MgI_2, H is evolved and the acid is con-

verted completely into the salt RCO_2MgI. This salt then undergoes reduction and, at least in the case of aromatic acids, the reduction product is R(IMgO)C:C(OMgI)R, which, when hydrolyzed, gives rise to the corresponding benzoin in yields of 30–75%. The reducing effect of the binary system is ascribed to the intermediate formation of the compd. MgI. Alkyl esters of aromatic acids and acyl peroxides are reduced by the binary system in a similar manner. Aryl esters are affected differently. The following % H liberated was found for the reaction $RCO_2H + Mg + MgI_2$: BzOH, 89; *p*-$MeC_6H_4CO_2H$, 81; α-$C_{10}H_7CO_2H$, 86; β-$C_{10}H_7CO_2H$, 93; $PhCH_2CO_2H$, 117; Ph_2CHCO_2H, 97; $C_{18}H_{36}O_2$, 87. The formation of H depends primarily upon the liberation of HI ($RCO_2H + MgI \rightleftharpoons RCO_2MgI + HI$), which then reacts with Mg($Mg + 2HI \longrightarrow MgI_2 + H_2$). Expts. are reported which confirm this equil. A mixt. of Mg + MgI from 95 g. I and 20 g. Mg in 100 cc. Et_2O and 200 cc. C_6H_6, treated with 30.5 g. BzOH, gives 30–43% of benzoin; *p*-$MeC_6H_4CO_2H$ gives 30% of dimethylbenzil; α-$C_{10}H_7CO_2H$ gives 30–5% α-naphthoin; β-$C_{10}H_7CO_2H$ gives 70–5% of *β-naphthil*, cream, m. 157–8°; *p*-$PhC_6H_4CO_2H$ gives 40% of *p,p'*-diphenylbenzil. $BzOCH_2Ph$ (53 g.) and 70 g. MgI in Et_2O-C_6H_6, heated on the steam bath for 1 week, give 30.32 g. BzOH and 20 g. $PhCH_2I$. Reduction of $BzOCH_2Ph$ gives 70% of $(PhCH_2)_2$ and 45% benzoin. BzOMe (34 g.) gives only 2.2 g. benzoin, the MeI reacting with the Mg to form a Grignard reagent, which in turn reacts with the ester or salt. BzOPh gives 90% of PhOH. Bz_2O_2 and MgI_2 in Et_2O-C_6H_6 liberate I quant., forming BzOH; reduction gives 45% of benzoin. The reduction of acids or of esters by this binary system offers a convenient method of obtaining benzoins. It should prove particularly useful in those instances when the aldehyde requisite for the usual benzoin condensation is not readily accessible. C. J. West

Action of phosgene on polypeptide-like derivatives of *p*-aminobenzoic acid. Formation of 1,3-substituted hydantoins. Caspar Tropp. Inst. Schiffs- u. Tropen-Krankheiten, Hamburg. *Ber.* **61B**, 1431–9(1928).—Germanin, a very large mol. built up of aromatic amino acids in polypeptide-like combination and doubled in size by conversion with $COCl_2$ into a urea deriv., has opened up an entirely new path in the field of modern chemotherapy. Attempts were made to convert the polypeptide-like glycyl and polyglycyl derivs. of *p*-$H_2NC_6H_4AsO_3H_2$ (cf. Giemsa and T., *C. A.* **21**, 70) in the same way into urea derivs. With the 1st member of the series, $H_2NCH_2CONHC_6H_4AsO_3H_2$, all such attempts failed; there was formed a non-cryst. gluey product of high mol. wt. drying to a glassy brittle mass. To study the mechanism of the reaction *p*-$H_2NC_6H_4CO_2H$ was substituted for the expensive atoxyl. $CO(NHCH_2CONHCH_2CO_2H)_2$ (I) is readily made by the Fischer method with $COCl_2$ and its prepn. has been materially simplified so that it can be obtained in 1 operation, without esterification or isolation of any intermediate product, from glycine anhydride. The complete absence of urea formation in T.'s expts. must therefore be due to the aryl substitution in the NH_2 group. *Glycyl-p-aminobenzoic acid* (II) cautiously treated in the cold with $COCl_2$ gave, not the urea, but *3-[4'-carboxyphenyl]hydantoin* (III). The *iminobis[acetyl-p-aminobenzoic acid]* (IV), formed as by-product in the prepn. of **II**, gives on similar treatment *1-[acetyl-p-aminobenzoic acid]-3-[4'-carboxyphenyl]hydantoin* (V), and *N-[(isoamylamino)acetyl]-p-aminobenzoic acid* (VI) yields *1-isoamyl-3-[4'-carboxyphenyl]-hydantoin* (VII). The Ph residue substituted on the N of the amide makes the other H atom so labile that the $COCl_2$ prefers the ring closure to urea formation. But the 2nd point of anchorage, the NH_2 group (and especially its substituents), is of the greatest significance in the formation of the 5-membered ring. As easily as the hydantoin is formed in the above cases, just as completely does it fail to be formed when, adjacent to the amine, there is a C:O group belonging to a mol. which has other negative substituents, as in *[chloroacetyl]glycyl-p-aminobenzoic acid* (VIII) and *[phenylureido]-acetylglycyl-p-aminobenzoic acid* (IX). The above syntheses show that a large no. of otherwise rather difficultly accessible 1,3-substituted hydantoins can be obtained easily and in good yield with $COCl_2$ (cf. Biltz and Slotta, *C. A.* **21**, 1794, who do not even mention the $COCl_2$ method in their enumeration of the methods of prepg. hydantoins because up to the present it had no practical application). The mechanism of the reaction with polyglycyl compds. of the above type is very complex; *diglycyl-p-aminobenzoic acid* (X) gives a non-cryst. product of high mol. wt. whose structure it has not yet been possible to establish. I is obtained in 55% yield from 5 g. glycine anhydride shaken 15 min. in 50 cc. *N* NaOH, then slowly treated in the cold with 8 g. of 25% $COCl_2$ in PhMe. *N-Chloroacetyl-p-aminobenzoic acid* (XI) (96.8% from *p*-$H_2NC_6H_4CO_2H$ in NaOH under a layer of Et_2O with $ClCH_2COCl$), m. 257–8°, gives with 10 parts concd. NH_4OH at incubator temp. 81% **II**, needles with 1 H_2O, m. 229° (decompn.). **IV**, which may become the chief product of the reaction if the **XI** is first mixed with H_2O

to a stiff paste and then treated with 3.5 parts concd. NH_4OH, decomps. above 250°. **III** (64% from **II** in NaOH under PhMe with $COCl_2$), begins to m. 258–60° (decompn.) on rapid heating, gives the Jaffé reaction with picric acid. **V** (1.7 g. from 3.7 g. **IV**), does not decomp. 270°. **VI.** *HCl* (2.5 g. from 6.3 g. **XI** and iso-$AmNH_2$), m. 285°. *[Diisoamylaminoacetyl]glycyl-p-aminobenzoic acid·HCl*, from **VIII** and (iso-Am)$_2$O in C_5H_5N, m. 253°. With hot C_5H_5N alone, 2.7 g. **VIII** gives 92% *[(p-carboxyphenyl)amino]glycylacetylpyridinium chloride*, crystals with 1.5 H_2O, m. 258°. **VII**, m. 189°. **VIII** (93% from **II** and $ClCH_2COCl$). **IX** (73% from **X** and PhNCO), m. 242°. **X** (5 g. from 8 g. **VIII** with concd. NH_4OH), m. 233°. C. A. R.

Reactions of α,β-unsaturated dinitriles. Ben B. Corson and Roger W. Stoughton. Middlebury College. *J. Am. Chem. Soc.* **50**, 2825–37(1928).—Condensation of $CH_2(CN)_2$ with the appropriate aldehyde, using piperidine or other alk. reagents, gives the following derivs. of *malononitrile;* benzal, m. 83.5–4° (96% yield), causes sneezing and tears; *p*-methoxybenzal, m. 114.5–5° (93%), *o-methoxybenzal*, straw, m. 84–4.5° (90%); *p-hydroxybenzal*, lemon, m. 188.5–9.5° (77%); *m-nitrobenzal*, light cream, m. 104.5–5° (90%), causes sneezing; *3,4-methylenedioxybenzal*, lemon, m. 199–200° (96%). *o-chlorobenzal*, m. 95–6° (85%), causes sneezing and is a skin irritant; *cyclohexylidene*, pale straw, m. 173.5–4.5° (30%); *3-methoxy-4-hydroxybenzal*, lemon, m. 133.5–4.5° (85%); fural, m. 72.5–3° (80%). These closely resemble α,β-unsatd. aldehydes and ketones in that they dissolve in $NaHSO_3$, are oxidized by $KMnO_4$, are reversed into the original components by NaOH and add the elements of HCN. By the reaction of KCN in EtOH, followed by addn. of HCl, the following derivs. of *α,β,β-tricyanoethane* were prepd.: *α-Ph*, m. 124.5–5° (90%); *α-[p-methoxyphenyl]*, cream, m. 122–2.5° (95%); *α-[o-methoxyphenyl]*, cream, m. 140.5–1° (95%); *α-[3,4-methylenedioxyphenyl]*, light orange, m. 153–3.5° (80%). In some cases the intermediate *K deriv.* was analyzed. The nitriles are readily sol. in NH_4OH and are recovered on acidification. From the NH_4 salts, the Ag salts are obtained with $AgNO_3$; the pure white salt darkens in the light. $PhCH(CN)CH(CN)_2$ and MeI give the Me deriv., $PhCH(CN)CMe(CN)_2$, m. 83–4°, whose structure was established by hydrolysis to $HO_2CCHPhCHMeCO_2H$, m. 182–3°. This acid was also synthesized as follows: PhCH:C(CN)CO_2Me and HCN give *Me β-phenyl-α,β-dicyanopropionate*, m. 100–1°; MeI gives the *α-Me deriv.*, m. 87–8°, hydrolyzed to the above acid, m. 182–3°. *p*-Methoxyphenylsuccinic acid, m. 207–8°; *di-Me ester*, m. 93–4°. *o-Methoxyphenylsuccinic acid*, m. 184–5°. C. J. West

Preparation of ethyl phenylmalonate and of 5-phenyl-β-hydroxyethylbarbituric acid. Wm. L. Nelson and Leonard H. Cretcher. Mellon Inst. of Industrial Research. *J. Am. Chem. Soc.* **50**, 2758–62(1298).—Detailed directions are given for the prepn. of $PhCH(CN)CO_2Et$ from $PhCH_2CN$ and Et_2CO_3 with $NaNH_2$ in Et_2O (70.3% yield) and its sapon. to $PhCH(CO_2Et)$ (**I**) by dry HCl in EtOH (78.3% yield); the Na salt with EtI gives 61% of the Et deriv. (**II**), b_{10} 170°, d_4^{23} 1.071. Heating 2.64 g. **II** with 0.69 g. Na in 11 g. abs. EtOH and 0.9 g. $CO(NH_2)_2$ for 3 hrs. at 115° gives 35% of 5-phenylethylbarbituric acid, m. 173–4°. Heating the Na compd. of **I** and $ClCH_2CH_2$-$OCH{:}CH_2$ at 140–50° for 14 hrs. gives 52% of *Et phenylvinyloxyethylmalonate*, b_{17} 196–7°, d_4^{20} 1.098; condensation with $CO(NH_2)_2$ gives 10% of *5-phenyl-β-hydroxyethylbarbituric acid* (hydroxyluminal), m. 200°; $CS(NH_2)_2$ gives 15% of the *2-thio deriv.*, m. 167°. *Phenylvinyloxyethylacetonitrile*, b_8 147°, d_4^{27} 1.029. C. J. West

β-Phenylethylmaleic acid and the isomeric β-phenylethylfumaric acid. P. Cordier. *Compt. rend.* **186**, 869–72(1928).—α-Hydroxy-α-acetonyl-γ-phenylbutyric acid (Bougault, *C. A.* **6**, 3273) is dehydrated by HCl to give α-[β-ketopropylidene]-γ-phenylbutyric acid, m. 95°. An aq. NaOH soln. of the mixt. of dibasic acids obtained by oxidation of the latter with alk. NaOCl yields, on acidification with AcOH, *Na H β-phenylethylmaleate* (the corresponding *acid*, m. 104°, affords the *anhydride*, m. 74°, on treatment with Ac_2O or with dil. HCl) *β-Phenylethylfumaric acid*, m. 202°, obtained from the mother-liquors, does not yield an anhydride under the former conditions. Both acids are reduced to β-phenylethylsuccinic acid by Na-Hg and the substituted fumaric acid is partly converted into its isomeride on treatment with $NaHSO_3$. B. C. A.

Reduction of monohydroxybenzoic acids by catalytic hydrogenation. Fr. Balaš and Alex. Kosík. Charles Univ., Prague. *Casopis Ceskoslovenského Lékárnictva* **7**, 105–7, 118–21, 136–8, 191–2(1927).—Reduction of aq. *o*-$HOC_6H_4CO_2H$ at 60° by H_2 in presence of colloidal Pt yields cyclohexanol as the final product. By analogous reduction of the *m*- and *p*-acids, hexahydrobenzoic acid is formed. W. J. H.

Derivatives of salicylic acid. I. 3-Nitro- and 5-nitrosalicylic acids. A. N. Meldrum and N. W. Hirve. *J. Indian Chem. Soc.* **5**, 95–101(1928). Nitration of

salicylic acid by the method of Meldola, Foster, and Brightman (*C. A.* **11,** 2459) yields a mixt. of 3-nitrosalicylic acid, m. 148–9° (+H_2O, m. 18–9°), and 5-nitrosalicylic acid, m. 228° (22.5 g. and 50 g., resp., from 100 g. of salicylic acid), which is best sepd. by crystn. of the K salts. A neutral soln. of the mixt. in KOH deposits the *mono-K salt* of the 3-nitro acid (yellow; corresponding *Na salt,* crimson), while treatment of the mother-liquors with excess of KOH yields the *di-K salt* of the 5-nitro acid (yellow; corresponding Na salt, yellow). Me 3-nitrosalicylate, m. 132° [the ester, described by Keller (*C. A.* **2,** 2086) is probably a mixt. of the isomeric esters; corresponding Et ester, m. 48.5°; corresponding amide, m. 155° (K salt, +H_2O, described)], and Me 5-nitrosalicylate, m. 119° [corresponding Et ester, m. 102°; corresponding amide, m. 225° (K salt, +H_2O, described)], are prepd. in the usual ways. B. C. A.

Derivatives of salicylylsalicylic acid. E. Lewicka. *Bull. acad. sci. Cracovie* **1927A,** 4 pp.—The following compds. are described: acetylsalicylyl chloride; *Me* (m. 82–4°) and *Et* (m. 72–3°) *acetylsalicylylsalicylates; Me methylsalicylylsalicylate,* m. 102–4°. B. C. A.

Synthesis of the β-acid (2,6-dihydroxyquinoline-4-carboxylic acid) obtained from crude oryzanin by hydrolysis. Yoshikazu Sahashi. *Biochem. Z.* **189,** 208–13(1927).—See *C. A.* **21,** 3904. S. Morgulis

Azo compounds of tyrosine. A. Morel and P. Sisley. *Bull. soc. chim.* **43,** 881–3(1928); cf. *C. A.* **22,** 1857.—Diazotizing with dil. HNO_2 and coupling with β-naphthol (I) produces *fibroinazo-β-naphthol* (II) in silk due to reactions of *tyrosine* (III). A study has been made of this reaction on III to det. whether the aliphatic NH_2 is eliminated, thus indicating whether III remains an integral part of the fiber when II is formed. Only a part (max 40%) of the NH_2 is liberated when III is treated with HNO_2 in the cold and dark. III (18 g.) was dissolved in 65 cc. of HCl and dild. to 2 l. The soln. was cooled to 10° and, while in the dark, a soln. contg. 35 g. of $NaNO_2$ in 500 cc. of H_2O was added during 1 hr. After standing cold and dark for 36 hrs., it was poured into a soln. of 15 g. of I in 1 l. of 0.7% NaOH contg. NH_4OH equiv. to the HCl and excess HNO_2. After 48 hrs. in the dark, HOAc gave 9 g. of red ppt. which was filtered off and washed. Crystn. from EtOH gave 2 compds., the more sol. one (IV) in the smallest quantity, the 2nd (V) being formed exclusively if the quantity of nitrite was decreased. The product is insol. in H_2O and sol. in alkalies, giving a blue which changes to red-brown with excess alkali. Silk dyed with this is not exactly the same shade as that formed directly in the fiber and is much less fast. This indicates a difference between II and the deriv. of III. V is *tyrosineazo-β-naphthol,* $HOC_{10}H_6N_2C_6H_3(OH)$-$CH_2CH(NH_2)CO_2H$, in which N_2 is *o* to the OH. IV is the corresponding *p-hydroxyphenyllactic acid deriv.,* $HOC_{10}H_6N_2C_6H_3(OH)CH_2CH(OH)CO_2H$. A. S. Carter

Oxidative degradation of carboxylic acids. Siegfried Skraup and Emil Schwamberger. Univ. Wurzburg. *Ann.* **462,** 135–58(1928).—Spiro (*C. A.* **16,** 1931) has shown that there is an oscillation in oxidation of fatty and arylfatty acids in the organism. S. and S. have sought to det if there is such a periodic behavior of these acids in their oxidation in the lab. In most of the expts. 1 mol. of the acid in 2 equivs. of K_2CO_3 were oxidized with 0.1 mol. $KMnO_4$ (3 atoms O). $PhCH_2CO_2H$, after 120 min., gives 0.89 mol BzOH (I); $PhCH(OH)CO_2H$, after 90 min., gives 0.38 mol. I and 0.26 mol. $BzCO_2H$ (II); $BzCO_2H$, after 360 min., gives 0.74 mol. I; since $PhCH_2$-CO_2H gives II only in about 50% of the expts., $PhCH(OH)CO_2H$ is not an intermediate product in its oxidation. $PhCH_2CH_2CO_2H$, after 120 min., gives 0.24 mol. I and 0.14 mol. II; $BzCH_2CO_2H$, after 15 min. ($KMnO_4$ dropped into the acid), gives 0.41 mol. I, 0.46 mol. $(CO_2H)_2$ and some PhAc; if the acid is added to the $KMnO_4$, there results 0.07 mol. I, 0.28 mol. II and traces of $(CO_2H)_2$; in the first case, the acid reacts principally as the enol. form, $PhC(OH):CHCO_2H$, for the isomeric $PhCH_2COCO_2H$ (about 10% enolized) gives 0.14 mol. BzH, 0.05 mol. I and 0.42% $(CO_2H)_2$. $PhCH:CHCO_2H$ after 5 mins. gives 0.47 mol. BzH, 0.20 mol. I and 0.33 mol. $(CO_2H)_2$; $PhCH(OH)$-$CH(OH)CO_2H$, after 10 min., gives 0.43 mol. BzH, 0.18 mol. I and 0.25 mol. $(CO_2H)_2$, so that these are not intermediate products in the oxidation of $PhCH_2CH_2CO_2H$. $PhCH_2CH_2CH_2CO_2H$, after 15 min., gives 0.3 mol. I and 0.13 mol. II; $BzCH_2CH_2CO_2H$, after 20 min., gives 0.44 mol. I. $Ph(CH_2)_4CO_2H$ gives after 30 min. 0.3 mol. I and 0.20 mol. $(CO_2H)_2$; $Bz(CH_2)_3CO_2H$ gives after 25 min. 0.22 mol. I and 0.29 mol. $(CO_2H)_2$. *Benzoylpropionic acid hydrazone anhydride,* m. 153° (90% yield); reduction gives *γ-phenylbutyric acid,* b_{13} 170, m. 50° (50% yield). *β-[p-Chlorobenzoyl]propionic acid,* from PhCl, succinic anhydride and $AlCl_3$, m. 131°; *hydrazone anhydride,* m. 178° (90% yield); *p-chlorophenylbutyric acid,* b_{12} 185°, m. 62° (30% yield). *γ-[p-Chlorophenyl]-butyrolactone,* b_{12} 140–50°, b_{15} 210°. $Ph(CH_2)_4CO_2H$ may be obtained by the catalytic reduction of cinnamalacetic acid. Using 5 atoms O, 5 g. $C_6H_{10}O_2$, $C_6H_{12}O_2$, $C_7H_{14}O_2$

and $C_8H_{16}O_2$ give 3.5, 2.9, 2.5 and 2.0 g., resp., of $(CO_2H)_2$. Suberic acid, after 3–4 hrs., gives 1.1 g. $(CO_2H)_2$; azelaic acid gives 1 g. $(CO_2H)_2$. Me stearate and PhMgBr give 75% of *1,1-diphenyloctadecene*, $Me(CH_2)_{16}CH:CPh_2$, b_{18} 282–3°, m. —1°; oxidation with CrO_3 gives 56% of $C_{17}H_{34}O_2$; the *Ph ester*, b_{11} 240–50° (considerable decompn.), m. 37°; heated 72 hrs. at 328°, 20 g. of the latter give 4 g. PhOH, 2.5 g. $C_{14}H_{30}$, 4.5 g. $C_{17}H_{34}O_2$ and 4 g. of the Ph ester. *Diphenylhexadecene*, b_{13} 265–70°, m. 17–8°; oxidation gives $C_{15}H_{30}O_2$. *1,1-Diphenyl-1,9-octadecadiene*, b_{15} 285–6°; oxidation gives *heptadecenic acid* (III), b_{20} 226–7°, m. —1°. H_2O_2 gives *dihydroxymargaric acid*, m. 94°. Oxidation of III gives pelargonic and suberic acids. Oxidation of diphenylcyclohexylethylene gives cyclohexanecarboxylic acid. *1-Methyl-4-diphenylmethylenecyclohexane*, m. 65°, on oxidation with CrO_3 gives *p*-methylcyclohexanone, m. 162°. C. J. WEST

Rotatory dispersion of certain isomeric butyl esters of *l*-mandelic acid. CHARLES E. WOOD, ALBERT ED. CHRISMAN AND SYDNEY D. NICHOLAS. Univ. of Birmingham. *J. Chem. Soc.* **1928**, 2180–90.—In the isomeric Bu mandelates, the iso-Bu ester shows an increase and the tert. ester a decrease of negative rotation when compared with the *n*-ester. Pronounced decrease in rotation takes place when there are 2 asym. centers of opposite sign in the mol., but without visual anomaly. For visual anomaly the partial rotations of the 2 asym. centers should be of comparable magnitude. All the esters exhibit normal and complex rotatory dispersion. Increase of temp. causes a decrease in rotation of the esters. No max. or min. occur in the temp.-rotation diagrams. Comparison of the rotational data of the 3 esters affords no generalization for relative configurational purposes. Rotational displacements in related series are discussed as a guide to configuration. Bu ester (I), m. 38.5° (cor.), d_4 1.0536, 1.0346, 1.0182, 0.9983 at 39.1, 61.1, 80 and 102.7°; iso-Bu ester (II), m. 35.5°, d_4 1.0536, 1.0337, 1.0173, 0.9977 at 38.5, 61.2, 80.1 and 102.3°; *tert-Bu ester* (III), m. 65°, d_4 1.0682, 1.0520, 1.0325, 1.0146 at 19, 37.5, 59.6, 79.6°; *di-sec-Bu ester* (IV), $b_{0.06}$ 88°; d_4 1.0746, 1.0623, 1.0410, 1.0209, 0.9992 at 3, 18, 43.5, 68.5 and 93°. Values for $[\alpha]^t_\lambda$ gives for I-IV for wave lengths from 6708 to 4359 for temps. corresponding approx. to the densities given. C. J. WEST

Constitution of rottlerin from Indian Kamala. S. DUTT AND D. P. GASWAMI. *J. Indian Chem. Soc.* 5, 21–4(1928); cf. *C. A.* 20, 182.—Nitration of heptaacetylrottlerin with HNO_3 (d 1.52) at the ordinary temp. yields *hexanitroheptaacetylrottlerin*, decompg. or exploding when heated (hexanitrorottlerin, exploding violently at about 200°, described), which, when oxidized with $KMnO_4$ in neutral soln., affords 2,4-dinitrobenzoic, 3,6-dinitrophthalic, and 2,5-dinitroterephthalic acids. Nitration of rottlerin hexa-Me ether under similar conditions leads to the formation of hexanitrorottlerin hexa-Me ether, decomps. on heating, which yields the same oxidation products. Heptaacetylrottlerin, on bromination in AcOH at 170°, affords *hexabromoheptaacetylrottlerin*, decomps. above 300° (*hexabromorottlerin*, unmelted on heating, described), which may be similarly oxidized to 2,4-dibromobenzoic, phthalic and terephthalic acids. The probable constitution of rottlerin is 2,5-[3,2,4,6-$Me(HO)_3C_6HCH_2CO]_2C_6H_3CH(OH)$-CH:CHPh. The substituting nitro groups enter the *o*- and *p*-positions in the styryl side-chain, the 3,6-positions in the central nucleus and the unoccupied positions in the phenolic nuclei. B. C. A.

A new bicyclic, doubly unsaturated hydrocarbon, isocamphodiene, and its hydration product, bornylenol. S. S. NAMETKIN AND ANTONINA ZABRODIN. Univ. Moskau. *Ber.* **61B**, 1491–4(1928).—The simple bicyclic hydrocarbons thus far known belong either to the satd. series (camphane, fenchane) or to the unsatd. series with 1 double bond (camphene, bornylene). The theoretically possible compds. with 2 double bonds are isomeric with C_6H_6 and its homologs and it is probably for this reason that all attempts hitherto made to prep. them have led to the formation only of aromatic compds. If it were possible to introduce the 2nd double bond into the camphene system, the problem would be solved. Because of the great strain to be expected in such a system it was essential to choose a method which would best insure the preservation of the bicyclic system without isomerization to the aromatic system. The method of exhaustive methylation was selected. α-Aminocamphene (I) was converted in the usual way into the quaternary base $C_{10}H_{15}NMe_3OH$ (II) which on cautious distn. yielded, besides the ordinary decompn. products, a cryst. hydrocarbon $C_{10}H_{14}$, unsatd. toward Br and $KMnO_4$ and shown by oxidation with BzO_2H to contain 2 double bonds; it is therefore designated as *isocamphodiene* or *camphenene* (III). The 2 double bonds (one cyclic and the other semicyclic) react with different velocities with AcOH; in the presence of H_2SO_4 is obtained an addn. product (IV), the *acetate* of an unsatd. bicyclic alc. $C_{10}H_{15}OH$, which, assuming that the hydration of III is accompanied by the same rearrangement as

in that of camphene, must correspond in structure to bornylene and is named ***bornylenol*** (V or VI). **III**, m. 41.5-2°, b_{763} 149-50°, similar in appearance, odor and volatility to camphene, reacts energetically with HNO_3, gives a characteristic reaction with H_2SO_4 in alc. (yellow color turning through red to dark red). **IV** (2.2 g. from 2.35 g. **III** with 6 g. AcOH contg. 0.2 g. 50% H_2SO_4 heated 6 hrs. at 55°), b_{18} 106-7°, d^{20} 1.0019, n^{20} 1.4662. **V**, b_{16} 103-4°, m. 60-1°, is very volatile and has an isoborneol-like odor.

The structure of the products obtained by addition of hydrochloric acid to bornylene. Osman Achmatowicz. *Roczniki Chem.* **8**, 55-70(1928); cf. *C. A.* **21**, 3612.—The HCl addn. yields the same product, $C_{10}H_{17}Cl$ (I), whether carried out in ether, ligroin, $CHCl_3$ or AcOH, in the presence or absence of a little water. It is prepd. preferably by satg. with HCl at 0° 50 g. bornylene in 50 g. $CHCl_3$. In the 1st 7 hrs. 89% of the total HCl is added, in the following 5 hrs. 11%. The crude yellowish crystals, m. 142-4°, have a disagreeable odor, repeatedly recrystd. from low boiling ligroin, m. 149-9.5°, $[\alpha]$ 15.43°, decomp. 190° and sublime easily. Yield 96%. $C_{10}H_{17}Br$ (II) m. 124-5°, $[\alpha]_D$ 6.52°, $C_{10}H_{17}I$ (III) liquid, m. 22-5° after undercooling, $[\alpha]_D$ 55.18°, turns pink in the light. On heating 4 g. I 12.5 hrs. with 100 g. water to 100° in the sealed tube 75% of the Cl is split off. From the water-insol. part a fraction was obtained with a low Cl content, b. up to 160°, which on distn. over Na yielded *cyclene*, m. 64-6°, b. 155-8°. The halogen of I, II and III is split off easily and quant. by $AgNO_3$. Fifty g. II in 450 g. 96% alc. was refluxed 24 hrs. with 50 g. water and 100 g. Zn dust, and the product was distd. with steam and extd. with ether. On redistn. it yielded a fraction, b. 157-65°, m. 141-4° (IV), and one b. 192-9° (V). IV was freed from unsatd. compds. by $KMnO_4$ and yielded *bornylane*. Fractional distn. of V yielded a compd. $C_{12}H_{22}O$, b_{742} 197-8°, mol. refraction 54.90. It is the *Et ether* of the *alc.*, b. 186°. The halogen was therefore in the α-position. This was confirmed by the reaction with AcOAg. A mixt. of 10 g. I, 30 g. AcOAg, 100 g. glacial AcOH and 1 g. water yielded after 4 weeks' standing a small quantity of a subliming *hydrocarbon* and an *ester* b_{14} 105-7°, of pleasant odor, which on sapon. yielded the alc., b. 186°. II reacts in the same manner. An attempt at ascertaining the position of the halogen with the aid of Grignard's reaction failed. The RMgBr obtained from II in large crystals was treated with dry O_2 and yielded on fractional distn. *bornylane*, an *unsatd. hydrocarbon*, m. 196-201° (sepd. by the acetylation of Bertram and Wahlbaum as an *ester*, b_{27} 110-14°, in a too small quantity to be examd.), *borneol*, and a *stereoisomer* of *hydrodicamphene*, b_{20} 195-6°, m. 85-7°, mol. wt. (cryoscopically) 276; 87.29% C, 12.37% H_2. III gave a similar result: a little borneol, much $C_{20}H_{34}$, and a mixt. of low-boiling hydrocarbons. The unsatd. C_xH_y from III yields *i-camphoric acid*, m. 208° (anhydride m. 220-1°), by 3 hrs. shaking of 6 g. with 300 cc. 5% $KMnO_4$ at room temp. It is therefore *bornylene*. At 166° I reacts violently with an equal part of aniline. The fractionated product is treated with 5% $KMnO_4$ at 70-80°. The nonvolatile part contg. neutral and acid substances is too small to be examd. The volatile part consists chiefly of *cyclene* and a small proportion of a *ketone*, the *oxime* of which m. 83-4°. It is probably the *ketocyclene* obtained by Godlewski in 1903. The compds. described are stereoisomers of the borneol series, representing the *endo-borneol* group, while the borneol series represents the *exo-borneol* group (Bredt). *Isoborneol* is a structural isomer of borneol (Wagner) and not a stereoisomer as believed by Bredt. Mary Jacobsen

Aromatic fluorine compounds. II. 4,4'-Difluoro-3-aminodiphenyl and 3,4,4'-trifluorodiphenyl. Günther Schiemann and Einar Bolstad. Techn. Hochschule Hannover. *Ber.* **61B**, 1403-9(1928); cf. *C. A.* **21**, 2668.—$(p\text{-}FC_6H_4)_2$ (I) can be obtained smoothly from $(H_2NC_6H_4)_2$ by the method described in the 1st paper and its prepn. on a large scale and its purification have been so improved that it is now a very readily available substance. For its nitration fuming HNO_3, HNO_3-AcOH, KNO_3 and $EtNO_2$ did not prove satisfactory, but boiling HNO_3 of d. 1.40 readily yielded as chief product (up to 70%) *4,4'-difluoro-3-nitrodiphenyl* (II), the position of the NO_2 group being established by conversion of the II with KOH in boiling MeOH into *4'-fluoro-4-methoxy-3-nitrodiphenyl*, bright yellow, m. 84° (this reaction, which yielded other products also, will be dealt with in a special paper). Attempts to oxidize II to a benzoic acid have not

succeeded, but it is readily reduced by Sn and HCl to the *3-amino compd.* (III). In III, which solidifies at room temp. with extraordinary slowness, the F atoms do not interfere with the formation of dyes. The diazotized III coupled with β-$C_{10}H_7NH_2$ to a brick-red *dye*, probably $H_2NC_{10}H_6N_2C_6H_3FC_6H_4F$, likewise with β-naphthol, and with Schaffer, R and G acids to red-brown, orange-red and crimson *dyes*, resp.; *p*-toluidine and benzidine gave yellow *dyes*. Furthermore III with tetrazotized benzidine gave an orange-red basic *dye*, probably $[FC_6H_4C_6H_2F(NH_2)N_2C_6H_4]_2$. Diazotized III in concd. HCl with HBF_4 gave 94.5% of the light yellow *4,4'-difluorodiphenylyl-3-diazonium borofluoride* (IV) which is so stable that after 1.5 months its N content still agreed satisfactorily with the calcd. value. As it decomps. at the remarkably low temp. of 87.5–8.5°, its dry decompn. offers no difficulties and readily yields up to 85% of the light brown *3,4,4'-trifluorodiphenyl* (V), m. 88.8° (cor.), which is stable although it contains 2 adjacent F atoms on 1 nucleus, but the facts that it was not obtained in pure white form and that it has d_4^{25} 1.43 (detd. by J. Rockstroh) indicate that autodecompn. is not excluded. In the prepn. of I the temp. was kept below −5° during the diazotization which was carried out in such concd. soln. (70 g. benzidine, 220 cc. concd. HCl and 210 cc. aq. $NaNO_2$) that on addn. of the calcd. 225 cc. of 40% HBF_4 a stiff magma was formed; yield of $(C_6H_4N_2BF_4)_2$, decomps. 137–8°, 95%. Thermal decompn. of this yielded more than 80% I (calcd. on the basis of the benzidine used). The pure I, purified better by distn. *in vacuo* than by crystn., b_{11} 115.6°, b_{14} 119°, and can be sublimed without change in the m. p. II, m. 94.6° (cor.). III (yield, 87%), faintly yellow liquid of $PhNH_2$-like odor, b_{13} 159–60°, b_{766} 293°, solidifies on long standing to white needles, m. 27.5° (cor.) (even cooling to −60° does not hasten the crystn.); *Ac deriv.*, m. 96.2°; *Bz deriv.*, m. 122–3°. C. A. R.

The action of gaseous hydrobromic acid on esters of the organic acids at ordinary pressures. Marius Séon. *Compt. rend.* **187**, 131–3(1928).—The decompn. of esters by the simultaneous action of heat and alkalies with the production of the corresponding alc. and acid is a very general and remarkable property of these substances. Expts. have been conducted to ascertain whether gaseous HBr at ordinary pressure would have a similar effect. Boiling HCO_2Am with HBr gas for 6 hrs. gives AmBr and HCO_2H to the extent of 14%. Boiling *o*-$HOC_6H_4CO_2Am$ and HBr for 5 hrs. gives PhOH, CO_2 and AmBr in 8% yield. The phenol is derived from $HOC_6H_4CO_2H$ formed as an intermediate product. With $AcOCH_2Ph$ in the cold and HBr gas for 12 hrs., AcOH and $PhCH_2Br$ are formed to the extent of 100%. $BzOCH_2Ph$ in the cold and HBr gas for 4 hrs. give $PhCH_2Br$ and BzOH in 100% yield. The following reaction occurs in the cold with HBr for 15 hrs.: $2AcOCH_2CH{\cdot}CH_2 + 4HBr \longrightarrow 2AcOH + CH_2BrCH_2CH_2Br$ (27%) + $MeCHBrCH_2Br$ (7.3%). From $AcCH_2CO_2Et$ in the cold and HBr for 2 hrs. EtBr, Me_2CO (47.3% yield) and a condensation product, distg. about 265° and partly freezing at 47°, which with alc. KOH gave Et 2,4-dimethylpyrone-3-carboxylate and the corresponding acid. Ph esters, *e. g.*, PhOBz and PhOAc resisted attack. Boiling cyclohexyl acetate with HBr for 8 hrs. gives AcOH and $C_6H_{11}Br$ (27% yield). Hence the general reaction can be written $RCOR' + HBr = RCO_2H + R'Br$ where R may be any univalent radical and R' another univalent radical either aliphatic, aromatic or cyclohexyl. Phenol functions differently. S. L. B. Etherton

Hylotropic-isomeric forms. IV. Karl Schaum. Univ. Giessen. *Ann.* **462**, 194–209(1928); cf. *C. A.* 10, 2691. S. classifies cases of polymorphism as follows: (1) Phys.; here identical units form different space-lattices; small differences in the mol. anistropy disappear on destroying the space-lattice, *i. e.*, the liquid obtained by just melting either form is the same. (2) Cryptochem., subdivided into metameric (2*a*) and polymeric (2*b*); the fused mass obtained from the 2 forms shows slight differences in 2*a* and 2*b*; 2*a* arises with complex mols. of fairly stable forms caused by intramol. change, while 2*b* is found with substances which tend to associate. High rates of interconversion are found in cases of 2*b*. (3) Chemical, which consists of 2 kinds. The first is further divided into metameric (3*a*) and polymorphic (3*b*). Under 3*a* are cases where the 2 forms in the fused state are quite different, there being in these cases 2 distinct chem. isomers, convertible into each other; in the *b* case, the fusions and interconversion are as in *a*. The 2nd form, giving very low interconversion velocities, is a limiting case of the 1st, each form contg. a mere trace of the unit corresponding with the 2nd form. A no. of substances have been investigated with a view to their classification on the above lines. Ph_2CO, α-form, m. 48°; β-form, m. 23°; m. p. dependent upon previous history of sample; very high rate of interconversion (*RI*). *p*-MeC_6H_4COPh, α-form, m. 55°, β-form, m. 52°; *RI* low. In both cases, the formation of the metastable form is aided by the prolonged heating at high temps. Fresh fusions of the different forms show great differences as regards supercooling and crystn., as well as small differences in phys.

properties. Probably 2*b*, possibly 3*b* in addn. Benzoin, *RI* low. $(BzCH_2)_2CO$, α-form, m. 60°, β-form, m. 110°; *RI*, moderate; case of 3*a*. Me mesityl oxide oxalate, *RI*, moderate; case of 3II*a*. Benzil-*o*-carboxylic acid, α-form, m. 130°, β-form, m. 143.5°; case of 3I*a* or 3II*a*, with transition temp. about 66°; *RI*, low. Betol, α-form, m. 95.5°, β-form, m. 93.5°; *RI* given. 3-Nitro-p-acetotoluide, β-form, m. 93.5°; α-form, m. 95°; *RI*, small; case of 3I*a*. 4,2-$H_2N(O_2N)C_6H_3Me$, β-form, m. 69.5°, α-form, m. 77 0°; the stability of the β-form is increased by heating; *RI* measured. 2,6-$(O_2N)_2C_6H_3Me$, β-form, m. 65.5°; γ-form, m. 48°; transition temp., 40.5°; heating has no effect upon this temp. *m*-$O_2NC_6H_4CO_2H$, *RI* moderate. 4,2,6-$Cl(O_2N)_2C_6H_2OH$ gives a metastable form below −3°. 1-$C_{10}H_7NO_2$ gives a metastable and a stable form at ordinary temps., rapidly passing into the latter. 4-Nitrotriphenylurea has a very low *RI*. Ph_3CH has a high *RI*. The following are given for the transition and m. ps. of the β-forms: CBr_4, 46.7°, 94 3°; succinic anhydride, 110.1°, 120.2°; orcinol, 53.3, 107.5°; *asym*-$Cl_4C_6HNH_2$, 117.8°, 118.1°; Et azoxybenzoate, 112.6°, 119.2°. Other less definite cases are discussed. C. J. West

Synthesis of ketophenols by Hoesch's method. A. Korczynski and A. Nowakowski. *Roczniki Chem.* **8**, 254-62(1928); *Bull. soc. chim.* [iv] **43**, 329–37; cf. *C. A.* **21**, 1256; Houben and Fischer, *C. A.* **22**, 237.—The condensations were carried out by satg. the ether solns. at room temp. with HCl in the presence of 0.5-1 g. $ZnCl_2$, which increases the yields. The product was kept on ice 2 hrs.—2 weeks until crystn. occurred. Ph_2O and anisole do not condense with nitriles, even with strongly negative substituents. Only addn. products were obtained. *$(C_6H_5)_2O.CH_3CN.2HCl$*, m. 124–6° (decompn), was obtained from 4.1 g. MeCN and 17 g. Ph_2O in 40 cc. ether at 0–5°. It is hygroscopic, insol. in ether and petroleum ether, sol. in alc., AcOH, $CHCl_3$ and cold water with decompn. Yield 1.2 g. without $ZnCl_2$, 2 8 g. with 0.5 g. $ZnCl_2$. *$C_6H_5OCH_3.CH_3CN.$-$2HCl$*, m. 104-12°. Yield 34%. Anisole and *p*-BrC_6H_4CN do not react. MeCN, PhCN or *p*-ClC_6H_4CN do not react with pyrocatechol, hydroquinone or their mono -or di-Me ethers. *4'-Nitro-2,4-dihydroxybenzophenone imide-HCl* is prepd. from 2.9 g. *p*-$NO_2C_6H_4CN$ and 2.2 g. resorcinol in 120 cc. ether, and soln. of the yellow crystals in 15 cc. 10% HCl at 50°. It is sol. in alc., $CHCl_3$, and cold glacial AcOH, and repptd. by ether. When boiled 15 min. with 30 parts water or a short time with alc. it yields *4'-nitro-2,4-dihydroxybenzophenone*, m. 200°, easily sol. in alc. and AcOH, less sol. in $CHCl_3$, ether and hot water. The aq. soln. gives a reddish brown color with $FeCl_3$, the KOH soln. is dark red. *4'-Bromo-2,4-dihydroxybenzophenone imide-HCl* from 4.5 g. nitrile and 3 g. resorcinol in 40 cc. ether, light yellow, yields on 2 min. boiling with little alc. and pptn. with water 50% *4'-bromo-2,4-dihydroxybenzophenone*, faintly yellow, faint violet color with $FeCl_3$ and a deep orange with KOH. (M. p. not given in original abstr.) 4'-Nitro-2,4,6-trihydroxybenzophenone is prepd. by boiling the product from 2.9 g. nitrile and 3.2 g. phloroglucinol in 120 cc. ether 10 min. with 30 cc. water, dark yellow, m. 244–5°, easily sol. in AcOH, acetone and alc., less sol. in acetone and ether. Yield 46%. It is colored azure by $FeCl_3$, dark red by KOH. *4'-Cl-2,4,5-trihydroxybenzophenone* is obtained by boiling the dark violet oil from 2.7 g. nitrile, 2.5 g. 1,2,4-$C_6H_3(OH)_3$ in 40 cc. ether 0.5 hrs. with 30 cc. water, light orange needles, from aq. alc., m. 260°, easily sol. in alc., scarcely sol. in AcOH. It is colored dark orange by $FeCl_3$, yellow by KOH. Yield 55%. The ether decanted from the condensation product yielded after the addn. of 15 cc. concd. HCl *p*-*$ClC_6H_4CONH_2$*. *4'-Cl-2,3,4-trihydroxybenzophenone* is prepd. by boiling the red oily condensation product 10 min. with little water in a CO_2 current and shaking out with ether. Yield 25%. Faintly yellow needles from dil. alc., m. 157 8°, easily sol. in org. solvents, sparingly sol. in cold water. *2,3'4,4',5-Pentahydroxybenzophenone* is prepd. by condensation of 4.7 g. 1,2,4-$C_6H_3(OAc)_2CN$ with 5 g. 1,2,4-$C_6H_3(OH)_3$, in 8 cc. ether, heating 10 min. on the water bath with 40 cc. 10% H_2SO_4 and refluxing the canary-yellow salt with 20 parts water. Yield 1.2 g. Yellow, m. 242°, sol. in org. solvents, slightly sol. in water. The KOH soln. is blood-red, the alc. soln. is colored green by $FeCl_3$. *4'-OH-2,3',4,6-tetramethoxybenzophenone imide* is prepd. by boiling the condensation product of 2.9 g. vanillonitrile and 3.3 g. $C_6H_3(OMe)_3$ 20 min. with 30 cc. water, addn. of a few drops NH_3, soln. in KOH, and neutralization with dil. HCl. It yields with 5 parts 5*N* HCl the *HCl salt*, sparingly sol. in cold water and easily hydrolyzed. The *H_2SO_4 salt* is formed by a few min. heating with a 15% H_2SO_4, yellow, easily sol. in cold alc., slightly sol. in water. It is hydrolyzed by hot water to *4'-OH-2,3',4,6-tetramethoxybenzophenone* (0.92 g.), small, wart-like aggregates from 80% AcOH, m. 242°. The dil. KOH soln. is light yellow. The warm alc. soln. is colored reddish brown by $FeCl_3$. *2',6'-Dimethoxy-2,4,6-trihydroxybenzophenone* is prepd. by boiling the product from 32 g. nitrile and 2.5 g. phloroglucinol 2 hrs. with 20 cc. water. Yield 0.42 g. Faintly yellow plates from

dil. alc., m. 216–8°, easily sol. in alc., benzene, AcOH, less sol. in ether and $CHCl_3$. The KOH soln. is yellow, the alc. soln. gives an azure color with $FeCl_3$. MeCN and Ph_2O in AmOH or benzene with $AlCl_3$ failed to condense, although the 1st soln. was heated to 100° and the 2nd to 80°. MARY JACOBSEN

Introduction of the benzyl group into the benzene nucleus with the aid of sulfonic acid esters. ZOLTÁN FÖLDI. *Ber.* **61B**, 1609–16(1928); cf. *C. A.* **21**, 1802.—It was shown in the earlier paper that sulfonic acid esters on heating decomp. into SO_3H acids and a bivalent radical which, under the influence of the SO_3H acid, changes either into an olefin or resinous substances of high mol. wt. Thus, $PhSO_3CH_2Ph$ (I) gives PhCH= which, depending on the conditions, condenses to phenylated cycloparaffins or an amorphous polymer. In the hope of arresting this condensation at a lower stage F. attempted to effect the decompn. of the I in solvents. With C_6H_6 he obtained, instead of the expected product, Ph_2CH_2 in good yield. He then tried representatives of various classes of compds. (hydrocarbons, phenols, phenol ethers, carboxylic esters and aldehydes); with few exceptions derivs. benzylated in the nucleus resulted. Positive substituents (alkyl, alkoxy, etc.) already present direct the entering $PhCH_2$ group to the *o*- and (chiefly) *p*-position. Di-derivs. are also always formed but in relatively small quantities and it is advisable to use the substance to be benzylated in large excess (2–5 times the wt. of the I). The temp. is kept as low as possible (best around 110–40°, since pure I itself decomps. 125°). The reaction generally goes to completion very rapidly (from a few min. to a few hrs., depending on the substance to be benzylated), and is usually strongly exothermic. From the product, H_2O exts nearly the calcd. quantity of $PhSO_3H$ but the other product of the reaction is not always obtained in good yield because of the formation of polybenzylated derivs. and of cycloparaffins. F. believes that the PhCH radical first adds to the C_6H_6 nucleus with intermediate formation of a bicyclic cyclopropane, $\left.\begin{array}{l} CH{:}CH.CH \\ | \qquad\quad | \\ CH{\cdot}CH.CH \end{array}\right\rangle CHPh$. To test this view, he treated I with various olefinic compds. (crotonic, tiglic, cinnamic acids, $PhCH{:}CHCO_2Et$), but although an exothermic reaction followed, the only product, besides $PhSO_3H$, which could be isolated was a highly polymerized, amorphous benzylidene deriv.; only with PhCH:-$CHCO_2Et$ was there obtained α-benzylcinnamic acid (II), which may have resulted from the rearrangement of $PhCH.CHPh.CHCO_2Et$ formed primarily. From 50 g. I refluxed in 200 cc. C_6H_6 were obtained 31 g. $PhSO_3H$, 26.8 g. CH_2Ph_2, b. 255–6°, m. 24°, and 4.5 g. of a mixt. of *o*- and *p*-$C_6H_4(CH_2Ph)_2$. PhMe yielded 85% *p*-MeC_6H_4-CH_2Ph (III), b_1 110°, b. 272–4°, and 14% of $MeC_6H_3(CH_2Ph)_2$ (with cold HNO_3 of d. 1.5, III gives *p*-$O_2NC_6H_4[3,4\text{-}Me(O_2N)C_6H_3]CH_2$, m. 142–3°). CH_2Ph_2 (8 g.) with 10 g. I at 110° gives 4.5 g. unchanged Ph_2CH_2 and barely 20% of *o*-$C_6H_4(CH_2Ph)_2$ contaminated with a little of the *o*-isomer. $PhNO_2$ gives only $PhSO_3H$ and a polymerization product; in 1 expt. with com. $PhNO_2$ contg. a little $C_6H_4(NO_2)_2$ was obtained a small quantity of a *benzyldinitrobenzene*, probably 3,5-$(O_2N)_2C_6H_3CH_2Ph$, m. 183–5°. PhOH yielded 25% *p*- and 30% *o-benzylphenol*, b. 303–7°, and 2.7% *benzyl Ph ether*, b. 284–6°. Anisole gave 77% *p-benzylanisole*, b. 288.95°. BzH yielded a light yellow amorphous substance of high mol. wt. From Me salicylate is obtained 56% of *Me 3-benzyl-6-hydroxybenzoate*, odorless and tasteless needles, b_1 134–8°, m. 79.80°; free acid, m. 135–6°, gives a violet-blue color with $FeCl_3$. II (yield, 12.5%), m. 157–8°. C. A. R.

Dibenzoylxylenes and dinaphthanthracenediquinones. IV. HENRI DE DIESBACH AND TONNY JANZEN. Univ. Fribourg (Suisse). *Helv. Chim. Acta* **11**, 724–30(1928).—*1,3-Dimethyl-2-amino-4,6-dibenzoylbenzene* (II), m. 188.5°, is obtained from the corresponding nitro derivative (I) by reduction with Fe dust. It is hardly sol. in boiling H_2O, dil. acids, Et_2O, sol. in C_6H_6, Me_2CO, hot alc. and hot AcOH. *2-Cl compd.* (III), m. 92.5°, obtained by diazotation of II, is sol. in every solvent but H_2O. The *2-Br deriv.*, m. 121–2°, is obtained similarly from II. *1,3-Dicarboxylic-2-chloro-4,5-dibenzoylbenzene* (IV), m. 155–7°, is obtained from III by oxidation in sealed tubes with HNO_3 (d. 1.15) at 170°. The corresponding *Br deriv.*, m. 206°, is obtained in the same way. *6-Chlorodinaphthanthracenediquinone* (V), obtained by heating IV in concd. H_2SO_4, sublimes without melting at about 320°. The corresponding *Br deriv.* is similar. *2,3,2′,3′-Diphthalyl-1,1′-dianthraquinonyl* (VI), obtained by heating V with Cu dust in $PhNO_2$, does not m. 360°, is sol. in concd. H_2SO_4. *Tetra[4′-ketonaphthalino-1′,2′,3′]-8,11,1–9,13,3–10,14,4–7,16,6-pyrene* (VII), obtained by dissolving VI in concd. H_2SO_4, adding Cu dust and heating, is insol. in everything but concd. H_2SO_4. The oxidation of I gives 3,5,2,6-$Bz_2(HO_2C)_2C_6HNO_2$ whose internal condensation in alk. soln. gives *6-nitrodinaphthanthracenediquinone* (IX). The reduction of the NO_2 group in IX with

$Na_2S_2O_4$, gives the *6-amino compd.* (**X**). By diazotation, **X** gives the *6-HO compd.* (**XI**), which sublimes without melting 300°. **XI** treated with $Na_2S_2O_4$ and oxidized with air gives an insol. salt. When the latter is treated with hot H_2SO_4, it gives a product which is assumed to be **XII**.

Action of magnesium organo-derivatives on trisubstituted acetonitriles. (Mme.) P. Ramart-Lucas and F. Salmon-Legagneur. *Bull. soc. chim.* [iv] **43**, 321–9 (1928); cf. *C. A.* **21**, 1626.—The hydrolysis of the ketimine HBr salts obtained by the action of PhMgBr on trisubstituted acetonitriles is most readily effected with NaOAc in AcOH soln. With $PhCH_2CPh_2CN$ in xylene, PhMgBr scarcely reacts, a small quantity of a *substance*, $C_{17}H_{12}O$ (crude), m. 153–4°, being obtained. $PhCH_2MgCl$ (3–5 mols.) affords Ph_2CHCH_2Ph in 70% yield, together with dibenzyl, no ketimine deriv. being produced. Ph_3CCN behaves similarly, and in view of the complete absence of $Ph\text{-}CH_2CN$ or dibenzyl ketone, the fission of the nitriles is represented: $CR_3CN + PhCH_2\text{-}Mg.Cl \longrightarrow CR_3CMgCl + (CH_2Ph)_2 + MgClCN$, the mechanism being attributed to the formation of an unstable complex between the Mg deriv., ether, and ketone in which several atoms are linked by "semivalencies" (cf. Perrin, *C. A.* **21**, 3774). Such complexes may yield on dissocn. the original products or fresh mols. The ketimine HBr salt of Me_2CHCPh_2COPh, m. 250° (decompn.).

B. C. A.

Absorption spectra of some phthaleins and sulfonephthaleins of phenol and *o*-cresol. R. C. Gibbs and C. V. Shapiro. *J. Am. Chem. Soc.* **50**, 2798–810(1928).—The absorption spectra of phenoltetrachloro-, *o*-cresol- and *o*-cresoltetrachlorophthaleins are discussed in their relation to that of phenolphthalein. Evidence is presented to support the view that the absorption of Ph_3CH derivs. is due primarily to the joint effect of the 3 Ph nuclei and not to the central methane C atom. The absorption spectra of phenolsulfonephthalein and *o*-cresolsulfonephthalein in neutral, aq., EtOH and H_2SO_4 solns. indicate that they possess the inner salt structure in EtOH but the quinoid hydrate in aq. solns. The absorption spectra of these sulfonephthaleins in weakly alk. solns. bring out the progress of hydrolysis of the dibasic salts at low concns. The implications of this fact with respect to their use as indicators are pointed out. In concd. alk. solns., both phenolsulfonephthalein and *o*-cresol-sulfonephthalein are converted largely into the colorless tribasic salts of the carbinolcarboxylic acid, although the reaction proceeds very much more rapidly with the former.

C. J. West

Tetraphenylethylene oxide (α-benzopinacol). JEANNE LÉVY AND ROGER LAGRAVE. *Bull. soc. chim.* [iv] **43**, 437–41(1928).—The reactivity of arylated ethylenic hydrocarbons toward BzO_2H depends partly on the mol. wt. and partly on the sym. or unsym. nature of the mol. Hydrocarbons such as stilbene, which possess a sym. mol. are less easily oxidized than unsym. triarylhydrocarbons (cf. *C. A.* **20,** 1610; Böeseken, *C. A.* **21,** 2877; Lévy and Lagrave, *C. A.* **21,** 3360). Tetraphenylethylene oxide, m. 193–4° in Hg, 198–9° in acid bath, prepd. by oxidation of $(:CPh_2)_2$ with BzO_2H in $CHCl_3$ soln., is identical with α-benzopinacolin. $(:CPh_2)_2$ is best prepd. from β-benzopinacolin, obtained by reduction of Ph_2CO with Zn and excess of AcCl (cf. Paal, *Ber.* **17,** 911–3(1884)), which with 2.25 mols. of EtMgBr affords a theoretical yield of $\alpha,\alpha,\alpha,\beta$-tetraphenylethanol, converted by AcCl into $(.CPh_2)_2$. Yields of oxide up to 43% can be obtained by Thorner and Zincke's process (*Ber.* **11,** 65–71, 1396–9(1878)), but replacement of the HCl by dil. H_2SO_4 leads to benzopinacol. No benzohydrol is isolated in these reactions, but 1–2% of $(:CPh_2)_2$ is formed. B. C. A.

New hydrogenation catalyzers. GUYOT. *Chimie et industrie* **Special No.** 410 (April 1928).—According to Fr. pat. 559,787, crude C_8H_{10} can be hydrogenated to C_8H_{14} at 300° by unpurified H_2 at a pressure of 100 atm. in presence of Na as catalyzer, provided both the C_8H_{10} and H_2 are dry. A very slow but distinct production of C_8H_{14} was obtained in the lab at 250° and 15 kg. per sq. cm. The characteristic property of Na as a catalyzer lies in the fact that it is unaffected by the usual catalyzer poisons, and should also be found in all catalyzers which, like Na, are liquid at the hydrogenating temp., provided there is vigorous agitation or provided an inert material offering a large contact surface, *e g*, MgO or infusorial earth, is present. G found that, though the catalytic activity of K is extremely small as compared with that of Na, the Na-K alloys, and particularly NaK and NaK_2, are exceptionally active at the temps. and pressures generally used for hydrogenation in presence of Ni. In the lab 1 kg of C_8H_{10} can easily be converted quantitatively into C_8H_{14} in presence of 2% MgO and 10% of alloy in a "Catalytic" hydrogenizer in 3 hrs. NaK and NaK_2 can be economically and almost quantitatively prepd. by fusing Na at 250–360° with an equiv. amt. of KOH.

A. PAPINEAU-COUTURE

Purification of naphthalene for hydrogenation purposes. GUYOT. *Chimie et industrie* **Special No.** 408–9(April 1928).—Com $C_{10}H_8$ is unaffected by treatment with small quantities of *chlorosulfoacetyl chloride* $(HSO_3CHClCOCl)$, but the S compds. which it contains as impurities, and which rapidly poison catalyzers used in its hydrogenation, are acted upon in such a manner that they can be completely removed by washing with H_2O and then distg. (details are given in Fr pat. 602,408). The new reagent is obtained by the action of 100% H_2SO_4 on CCl_2 CHCl at 90°, $CHCl:CCl_2 + H_2SO_4 = HSO_3CHClCOCl + HCl$. Attempts to isolate it sufficiently pure for analytical purposes were unsuccessful; but its constitution is definitely established by the following reaction: (1) It dissolves almost instantly in H_2O with formation of practically equiv. proportions of HCl and of $HSO_3CHClCO_2H$ which was identified by its Ba salt; (2) On heating in vacuum to a moderate temp with an org acid it gives the corresponding chloride: $HSO_3CHClCOCl + RCO_2H = HSO_3CHClCO_2H + ROCl$, *e. g*, with $ClCH_2$-CO_2H it gives a large (but not quant) yield of $ClCH_2COCl$ together with a small quantity of $(ClCH_2CO)_2O$. In this reaction org acids can be replaced by their esters, *e g.*, with $(CO_2Et)_2$ there is obtained EtO_2CCOCl. In the reaction of H_2SO_4 and $CCl_2 \cdot CHCl$, in addn. to the main product, there is obtained some H_2SO_4 and $ClCH_2CO_2H$, produced by a secondary reaction (decompn. of the chloride by H_2O). In Fr. pat. 503,158 the action of H_2SO_4 on $CCl_2:CHCl$ is used for the prepn. of $ClCH_2CO_2H$, and in Swed. pat. 82,192 for the prepn. of $ClCH_2COCl$; but in both cases the primary reaction seems to have been missed. A. PAPINEAU-COUTURE

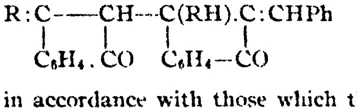
Amino alcohols of the naphthalene series. E. FOURNEAU, TRÉFOUEL, J. AND TRÉFOUEL, MME. J. *Bull. soc. chim.* [iv] **43,** 454–8(1928).—A no. of amino-alcs. of mol. wt. approaching that of quinine and of amino-alcs. of the benzene series contg. a MeO group or a piperidine ring have been prepd. The following are described: *α-dimethylamino-γ-1-naphthyl-*, b_{28} 216–7° (*HCl salt*, m. 134°), *α-diethylamino-γ-1-naphthyl-*, b_{19} 214° (*HCl salt*, m. 138°); *α-diamylamino-γ-1-naphthyl-*, b_{22} 240° (*HCl salt*, m. 114°); and *α-piperidino-γ-1-naphthylisopropyl alc.*, b_{10} 228° (*HCl salt*, m. 145°). The foregoing compds. were all obtained from *α-chloro-γ-1-naphthylisopropyl alc.*, b_{25} 210° (from α-$C_{10}H_7MgBr$ and epichlorohydrin), or from *γ-1-naphthyl-α,β-propylene oxide*, b_{15} 186°, obtained by the action of NaOH on the chlorohydrin in alc. *γ-4-Methoxy-1-naphthyl-α,β-propylene oxide*, b_{25} 225°, *α-chloro-γ-4-methoxy-1-naphthyl-*, $b_{0.2}$ 180°, and *α-piperidino-γ-4-methoxy-1-naphthylisopropyl alc.*, $b_{0.1}$ 200° (*HCl salt*, m. 193–4°), are similarly prepd. *1-Bromo-4-methoxynaphthalene*, b_{15} 178°, is obtained by brominat-

ing α-$C_{10}H_7OMe$ in AcOH. *γ-Chloro-α-phenylisopropyl alc.*, b_{20} 135–55°, *γ-phenyl-α,β-propylene oxide*, b_{39} 113°, *α-piperidino-γ-phenylisopropyl alc.*, b_{12} 172° (*HCl salt*, m. 178–9°); *γ-chloro-α-p-methoxyphenylisopropyl alc.*, b_{24} 188–90°, *γ-p-methoxyphenyl-α,β-propylene oxide*, b. 145–50°, and *α-piperidino-γ-p-methoxyphenylisopropyl alc.*, b_{18} 213° (*HCl salt*, m. 164°), are described. α-Naphthol condensed with epichlorohydrin in presence of NaOH affords *γ-1-naphthoxy-α,β-propylene oxide*, b_{16} 194°, from which *α-piperidino-γ-1-naphthoxy-*, $b_{0.2}$ 196° (*HCl salt*, m. 177–8°), and *α-diethylamino-γ-1-naphthoxyisopropyl alc.*, $b_{0.2}$ 176° (*HCl salt*, m. 125°), are obtained. *γ-2-Naphthoxy-α,β-propylene oxide*, b_{16} 200°, *α-piperidino-γ-2-naphthoxyisopropyl alc.*, $b_{0.15}$ 200° (*HCl salt*, m. 172–3°), and *α-diethylamino-γ-2-naphthoxyisopropyl alc*, $b_{0.6}$ 190° (*HCl salt*, m. 162°), are also described. B. C. A.

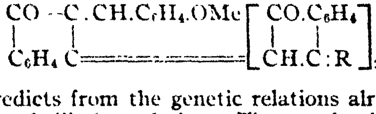
ar-α-Substituted hydrindenes. Erich Goth. Univ. Freiburg i. Br. *Ber.* **61B,** 1459–60(1928).—In the prepn. of *ar-β*-nitro- and *ar-β*-aminohydrindene large quantities of the α-isomers are also formed. As Borsche and Bodenstein's (*C. A.* **21,** 84) and Lindner and Bruhin's (*C. A.* **21,** 1647) descriptions of the α-NH_2 compd. (I) do not agree, its properties have been studied. It was found to m. —3° (B. and B., 9°; L. and B., - 2°). Ac deriv., m. 126° (B. and B., 40 1°; L. and B., 126–7°). Bz deriv., m. 136° (B. and B., 136°). Diazotization of I gave the α-HO compd., b_{12} 120°, m. 47-51°, described by Moschner as an oil. C. A. R.

Synthesis of ternary aliphatic arsines with the aid of the Grignard reagent. E. Gryszkiewicz-Trochimowski. *Roczniki Chem.* **8,** 250–3(1928); cf. *C. A.* **21,** 3612.—The following compds. were obtained from RCl, Mg and As_2O_3: *Tri-n-butylarsine*, b_8 102–4°, d^4_{21} 0.9931, n^{21}_α 1.4720, n^{21}_D 1.4752, n^{21}_β 1.4833, n^{21}_γ 1.4901. Yield 70%. *Tri-n-amylarsine*, b_{10} 146–9°, $d^4_{18.5}$ 0.9799, $n^{18.5}_\alpha$ 1.4736, $n^{18.5}_D$ 1.4767, $n^{18.5}_\beta$ 1.4844. Yield 80%. *Tri-n-hexylarsine*, b_{6-7} 169°, $d^4_{22.5}$ 0.9600, $n^{22.5}_\alpha$ 1.4726, $n^{22.5}_D$ 1.4751, $n^{22.5}_\beta$ 1.4825, $n^{22.5}_\gamma$ 1.4888. Yield 60%. *Tri-n-heptylarsine*, of pleasant odor, b_9 197–9°, d^4_{17} 0.9568, n^{17}_α 1.4746, n^{17}_D 1.4775, n^{17}_β 1.4856, n^{17}_γ 1.4908. Yield 65%. *Tri-n-octylarsine*, b_{9-10} 238–40°, d^4_{19} 0.9357, n^{19}_α 1.4721, n^{19}_D 1.4750, n^{19}_β 1.4821. Yield 70%. The odor resembles that of octyl alc. Mary Jacobsen

Truxenequinone. Genetic relation between indanedione, diindone, and truxenequinone. II. Mircea V. Ionescu. *Bull. soc. chim.* [iv] **43,** 447–53(1928).—Further investigations have shown that the additive reactions of diindone with carbindogenides, like the substitution reactions in presence of piperidine (cf. *C. A.* **21,** 2666, 3362), are detd. by the nature of the aryl group. Thus di-indone and BzH in pyridine afford *benzylideneindandionylideneindandionediindone* (I; R =C_6H_4<CO CO>C:), yellow, m. 255–6°, while anisaldehyde yields *anisylideneindandionylidenebisdiindone* (II), yellow, m. 242°, and piperonal the true bisindone indigenoid, *piperonylidenediindone* (III), brownish red, m. 267°. These reactions are

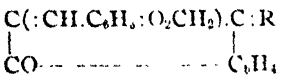


(I)

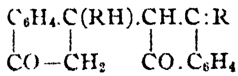


(II)

in accordance with those which theory predicts from the genetic relations already established (*loc. cit.*) between indanedione and diindene derivs. The mechanism previously suggested to explain the formation of truxenequinone from diindone admits of the intermediate stages (IV) and (V) or (VI), derivs. of type (IV) being already known.

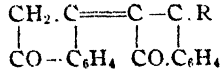


(III)



(IV)

(V) (*cis*)



(VI) (*trans.*)

A *trans-deriv.* of type (VI), *trans-anhydrotrisindandione*, m. 332–5°, has now been isolated in about 20% yield, by the action of indandione in benzene on diindene in xylene in presence of piperidine, thus confirming the views previously advanced. B. C. A.

Dimethyl phthalate and other esters of o-phthalic acid. J. A. Handy and L. F. Hoyt. *J. Am. Pharm. Assoc.* **17,** 458–61(1928).—The di-Me ester does not become

turbid in H_2O. It costs more than the di-Et ester, its d. is greater and it is less readily available. The properties of several other esters are tabulated. None of them are as applicable for denaturing purposes as the di-Me or di-Et esters. L. E. WARREN

The importance of the absorption method in the chemistry of the terpenes. ARNO MÜLLER. *Riechstoffind.* **1927,** 98–100; *Chem. Zentr.* 1927, II, 1347.—The measurement of the spectra in the ultra-violet should be used to clear up the constitution and isomerism of the terpenes along with other general methods. Plainly visible changes in the absorption curves are evident with differences in b. p. of 10% *in vacuo.* The usefulness of this method is shown by means of a no. of curves. J. S. REICHERT

Camphor group. IV. Preparation of *p*-ketoborneol. Y. MURAYAMA AND K. OTSUKA. Tokyo Imp. Hyg. Lab. *J. Pharm. Soc. Japan* No. **539,** 24–7(1927).—*p*-Ketoborneol of Bredt and his coworkers (*C. A.* **16,** 250; **18,** 826) was prepd. from bornyl monochloroacetate or trichloroacetate by oxidation with CrO_3 (yield 32%). *p-Ketobornyl monochloroacetate,* m. 85–6°. *Semicarbazone,* m. 228°. *p-Ketobornyl trichloroacetate,* m. 77–9°. *Semicarbazone,* m. 220°. NAO UYEI

Hydrogenation of some acyclic terpenes. S. SABETAY AND J. BLÉGER. Houbigant Lab., Puteaux, Seine. *Bull. soc. chim.* **43,** 839–45(1928).—From 52 g. rhodinol, dissolved in 200 cc. 75% alc. and reduced with H for 1.5 hrs. using Pt as catalyst, was obtained >40 g. dihydrorhodinol (I), rose-like odor, n_D^{15} 1.4370, d_{18} 0.830. *Acetate* (12 g. from 10 g. I and 8 g. Ac_2O), b_{18} 115.5-6°, n_D^{11} 1.4283. Geraniol (b_{12} 113–4°, n_D^{20} 1.4760), reduced as above, gave tetrahydrogeraniol, b_{13} 106.5–7°, n_D^{17} 1.4368. Fifty-five g. citronellal (b_{15} 90–2°, n_D^{18} 1.4475, $[\alpha]_D^{14}$ 11.53°, d_{18}^4 0.855, $[\alpha]_{Hg5461}^{14}$ 14.36°) was dissolved in 200 cc. 75% alc. and 12 g. Pt added in 2 portions. When 1 mol. H had been absorbed, absorption ceased. The product, dihydrocitronellal (II), lemon odor, b_{13} 81.5–2°, n_D^{17} 1.4273, d_{17}^4 0.822, $[\alpha]_D^{12}$ 10.80°, $[\alpha]_{Hg5461}^{12}$ 13.33°. (Cf. *C. A.* **18,** 969.) II oxidized in Me_2CO with $KMnO_4$ gave dihydrocitronellic acid, b_{14} 138–9°, n_D^{19} 1.4338. L. K.

The preparation of ethyl β-furylacrylate from furfural. HENRY GILMAN, R. E. BROWN AND H. L. JONES. Iowa State College. *Iowa State College J. Sci.* **2,** 317–9 (1928).—The yield of Et β-furylacrylate prepd. by the Claisen condensation has been raised from 36.1% to 63.3%. To a 2 l., 3-neck, round-bottom flask contg. 1.25 atoms of powd. Na in a freezing mixt. 4.66 moles of cold abs. EtOAc is added. The mixt. is stirred vigorously until a temp. of −10° is reached, after which 1 mole of furfural is added drop by drop with continued stirring. If rise of temp. and the appearance of a reddish brown color on the particles of Na do not indicate that the reaction has started when 1 cc. of furfural has been added, stirring should be stopped until bubbles rise from the Na. After the addn. of the furfural (about 2 hrs.) stirring is continued for 0.5 hr. in the cold and 1 hr. at room temp. Then, through the separatory funnel, is added 2.1 moles of AcOH followed by 500 cc. of water. The yields corresponding to the indicated temps. are as follows: 0° to 5°, 48.2%-56.4%; −10° to −4°, 60.3%; −15° to −14°, 60.3%-63.3%. Lower temps. increase the yield very little but increase the time required. Substitution of petroleum ether for part of the EtOAc decreases the yield very much. F. E. BROWN

Mononitro- and dinitrothiophenes. V. S. BABASINIAN. Lehigh Univ. *J. Am. Chem. Soc.* **50,** 2748–53(1928).—Detailed directions are given for the nitration of thiophene, using 84 g. thiophene in 340 cc. Ac_2O and 80 g. HNO_3 (d. 1.52) in 600 cc. glacial AcOH, the reaction being carried out at 10°; the yield of the mono-NO_2 compd. is 80%. HNO_3 (d. 1.4) (35 g.) in 55 g. H_2SO_4 (d. 1.82), treated in g.-portions with 20 g. mono-NO_2 deriv., gives 80% of the di-NO_2 deriv., m. 52°. Study of the di-NO_2 deriv. does not confirm the assertion that the ordinarily prepd. compd. is transformed into a higher-melting isomer (cf. Meyer and Stadler, *Ber.* **17,** 2648(1884)). However, the ordinary di-NO_2 deriv. contains a weighable quantity of the isomer, m. 78°. C. J. W.

Action of phenyl magnesium bromide on methyl *o*-cyanobenzoate. 1,3-Diphenyldihydroisoindole. DAVID R. BOYD AND DONALD E. LADHAMS. Univ. College, Southampton. *J. Chem. Soc.* **1928,** 2089–93.—o-$NCC_6H_4CO_2Me$ and PhMgBr give 90% of *1-hydroxy-1,3-diphenylisoindole-HBr,* yellow, decomps. above 220°; the free *base,* m. 192.5° (decompn.); crystn. of the salt from EtOH or heating the base with EtOH-KOH or dil. H_2SO_4 gives quant. o-$C_6H_4Bz_2$. The base in concd. H_2SO_4 gives a magenta-colored soln., thus behaving like a tert. aromatic carbinol. Reduction of the base gives a poor yield of *1,3-diphenyldihydroisoindole,* m. 109°; *HCl salt,* m. 270–80° (decompn.); oxidation gives only $C_6H_4Bz_2$. It behaves like a strong sec. base, yielding a *NO deriv.,* m. 175–5.5°; *Bz deriv.,* m. 236°; *p-toluenesulfonyl deriv.,* m. 255° (decompn.). C. J. WEST

Derivatives of ψ-indoxylspirocyclohexane. RAYMOND L. BETTS AND SYDNEY G. P. PLANT. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* **1928**, 2070-4.—It has recently been shown (*C. A.* **21**, 2882) that ψ-indoxylspirocyclohexane and ψ-indoxylspirocyclopentane, although having many reactions in common, differ in some respects. For this reason certain of the derivs. of the former have been studied. p-$MeC_6H_4NH_2$, cyclohexanone and KCN in AcOH give *1-p-toluidino-1-cyanocyclohexane*, m. 76°; concd. H_2SO_4 at room temp. give the *1-carboxamide*, m. 156°, hydrolyzed by boiling concd. HCl to the *acid*, m. 172°; with KOH at 350-60°, the latter gives *10-methyl-ψ-indoxylspirocyclohexane* (I), m. 164°; *7-Ac deriv.*, m. 144°; 2 g. **I**, 40 cc. H_2O and 10 cc. HNO_3 (d. 1.4) give the *8(?)-NO_2 deriv.*, yellow, m. 158°. *1-o-Toluidino-1-cyanocyclohexane*, m. 72°; the *carboxamide*, m. 143°, and the free *acid*, 117°; *8-methyl-ψ-indoxylspirocyclohexane*, m. 197°; *7-Ac deriv.*, m. 226°; *10(?)-NO_2 deriv.*, pale yellow, m. 273-4°. *1-2′,4′-Dimethylanilino-1-cyanohexane*, m. 115-6°; *1-carboxamide*, m. 133°; free *acid*, m. 125°; *8,10-dimethyl-ψ-indoxylspirocyclohexane*, m. 190°; *7-Ac deriv.*, m. 96°; *NO_2 deriv.*, pale yellow, m. 183-4°. *1-Anilino-1-cyano-4-methylcyclohexane*, m. 107°; *1-carboxamide*, m. 161°; free *acid*, m. 179°; *4-methyl-ψ-indoxylspirocyclohexane*, m. 189°; *7-Ac deriv.*, m. 102°; *10(?)-NO_2 deriv.*, pale yellow, m. 141°. *1-p-Nitroanilino-1-cyanocyclohexane*, pale yellow, m. 134°; the *carboxamide*, yellow, m. 217°; the free *acid*, yellow, m. 201°; reduction with $FeSO_4$ and NH_4OH gives *1-p-aminoanilinocyclohexane-1-carboxylic acid*, m. 216-7°; heating with KOH completely decomps. the acid. Attempts to reduce the NO_2 group in the above compds. have thus far been unsuccessful. C. J. WEST

Some new derivatives of histamine. P. VAN DER MERWE. Univ. Göttingen. *Z. physiol. Chem.* **177**, 301-14(1928).—Histamine derivs. thus far prepd. are much less active physiologically than the parent histamine itself. The alkyl derivs. previously described do not include substitution in position 2 of the imidazole ring. A series of such derivs. has now been prepd., but they appear to have no useful therapeutic properties. The method consists in opening up the histamine mol. by treatment with BzCl and NaOH, whereby $BzNHCH{:}C(NHBz)CH_2CH_2NHBz$ (I) is first formed, and this when heated to 150° with an acid anhydride yields the corresponding 2-alkylhistamine. Thus Ac_2O yields 54% of *2-methylhistamine* (*picrate* m. 237°; *HCl salt* m. 217°); $(EtCO)_2O$ yields 50% of *2-ethylhistamine* (*picrate* m. 219°; *HCl salt* m. 209°); Bz_2O yields 20% of *2-phenylhistamine* (*picrate* m. 230°; *HCl salt* decomps. 240°); and $(PhCH_2CO)_2O$ yields 18% of *2-benzylhistamine* (*picrate* m. 195°; *HCl salt* decomps. 245°). *N-Acetylhistamine*, m. 143°, was obtained in 80% yield from histamine and Ac_2O, and *N-isobutyrylhistamine*, m. 123°, from histamine and $(Me_2CHCO)_2O$. *β-4-Imidazolylethylurea*, m. 148° (*picrate* m. 150°; *oxalate* m. 153°), was prepd. in 50% yield from KOCN and histamine-HCl; *β-4-imidazolylethylphenylurea*, m. 178°, from PhNCO and histamine in Et_2O in nearly quant. yield; and *β-4-imidazolylethyl-α-naphthylurea*, m. 193°, from histamine and α-$C_{10}H_7NCO$. Histamine reacts with $CNNH_2$ at 100° to form *β-4-imidazolylethylguanidine* (*picrate*, m. 245°; *HCl salt*, m. 208°, both with decompn.). Condensation of histamine with p-$MeOC_6H_4CHO$ yields *N-p-methoxybenzalhistamine*, m. 186°; *picrate* m. 222°. Hydrogenation with Na and AmOH converts this into *N-p-methoxybenzylhistamine* (*picrate* m. 213°; *HCl salt*). Treatment with BzCl and NaOH then opens up the ring with formation of *4-p-methoxybenzyl-1,2,4-tris[benzoylamino]butene* m. 205°. Piperonal condenses in the same manner as anisic aldehyde to yield *methylenedioxybenzalhistamine*, m. 180° (*picrate* m. 217°), which may be hydrogenated to the corresponding *benzyl deriv.* (*picrate* m. 195°; *di-HCl salt* m. 245° (decompn.)). *N-ε-Aminoamylhistamine* (*tetrapicrate* m. 215°; *tripicrate* m. 169°) was obtained by condensing ε-chloroamylbenzamide with histamine and removing Bz by sapon. None of these derivs. is of particular interest pharmacologically. A. W. DOX

Phenylene-2,N-aryltriazolylene ketones and phenylene-2,N-phenyltriazolylenemethane (1,2,3-triazole analogs of fluorene and fluorenone). G. CHARRIER. Istituto di Chimica Generale, Pavia and Istituto di Chimica Farmaceutica e Tossicologica, Siena. *Gazz. chim. ital.* **58**, 254-60(1928).—Na phenylene-2-N-phenyltriazolyleneglycolate (cf. *C. A.* **19**, 2205) (10.5 g.) added to $K_2Cr_2O_7$ (22.5 g.) and concd. H_2SO_4 (69 g.) in water (112 g.), let cool, dild. with water, filtered, washed with water, recrystd. twice from EtOH, yields 100% of *phenylene-2-N-phenyl-1,2,3-triazolylene ketone* (I), lemon-yellow, m. 158°. A slight excess of $HONH_3Cl$ and Na_2CO_3 added to alc. **I** and the product recrystd. from EtOH yields the *oxime* of **I**, m. 223°. **I** and $PhHNNH_2$ (1 mol.) boiled 3-4 hrs. in EtOH, cooled, filtered and recrystd. from EtOH, yields 100% of the *phenylhydrazone* of **I**, golden yellow, m. 214°. With p-$ClC_6H_4NHNH_2$ instead of $PhHNNH_2$ and recrystn. of the product from glacial AcOH, there is obtained the *p-chlorophenylhydrazone* of **I**, greenish yellow, m. 226°. Alc. **I** refluxed

with $H_2NHNCONH_2.HCl$ (1 mol.) and Na_2CO_3, the product washed with water and boiling EtOH yields 100% of the *semicarbazone* of I, $C_6H_4.C_2N_3Ph.C{:}NNHCONH_2$, light yellow, m. 309°. I (2 parts) boiled 2 hrs. with red P (1 part) and aq. HI (40 cc. of 57% or of d_{15} 1.70), more HI (40 cc.) added, boiled 3-4 hrs. longer, cooled, poured in water, made alk. with NH_4OH, let settle, filtered, washed with water, the residue dried, extd. with boiling AcOH, filtered, the soln. dild. with water and the ppt. purified and recrystd. several times from EtOH, yields *phenylene-2-N-phenyl-1,2,3-triazolylene-methane* $C_6H_4.C_2N_3Ph.CH_2$. m. 128°, gives slightly fluorescent solns. in org. solvents. *2-N-p-Tolylnaphthotriazolequinone* (which will be described in a forthcoming note) treated with boiling dil. NaOH like the 2-*N*-Ph homolog (cf. *Gazz. chim. ital.* **54,** 984 (1924)) forms *phenylene-2-N-p-tolyltriazolyleneglycolic acid*, $C_6H_4.C_2N_3(C_6H_4Me\text{-}p)C(OH)CO_2H$, m. 194° (decompn.); *Na salt* (II), m. 205° (decompn.). Oxidized with chromic mixt. under the same conditions as those used for the 2-*N*-Ph compd. **II** is transformed into *phenylene-2-N-p-tolyltriazolylene ketone*, golden yellow, m. 196°, with $PhHNNH_2$ it forms a *phenylhydrazone* $C_{16}H_{11}N_3{:}NNHPh$, m. 207°, and with H_2NH-$NCONH_2.HCl$ it forms a *semicarbazone* $C_{16}H_{11}N_3.NNHCONH_2$, light yellow, m. 228° C. C. Davis

Styrylpyrylium salts. X. Anhydropyrylium bases and spiropyrans derived from dibenzyl ketone. Robert Dickinson, Isidor M. Heilbron and Florence O'Brien. Univ. of Liverpool. *J. Chem. Soc.* **1928,** 2077-82; cf. *C. A.* **21,** 3195.—$(PhCH_2)_2CO$ (20 g.) and 11.6 g. o-HOC_6H_4CHO in 30 cc. EtOH with 25 drops of piperidine give 18 g. of *2-hydroxy-α-phenylstyryl benzyl ketone* (I), pale yellow, m. 177°; *semicarbazone*, pale yellow, m. 196°; *Me ether*, pale yellow, m. 140-1°. With HCl in EtOH, cooled in a freezing mixt. while being satd., 5 g. $(PhCH_2)_2CO$ and 2.9 g. o-HOC_6H_4CHO give 5.5 g. *2-benzylidene-3-phenyl-Δ^3-benzopyran*, golden yellow, m. 115°, also obtained by satg. I in EtOH with HCl; it is recovered unchanged after boiling 30 hrs. with excess EtONa. If, during the satn. with HCl, the mixt. is cooled with ice H_2O, there results *3,3'-diphenyldibenzospiropyran*, m. 197°; no color develops when heated in Ph_2O. This compd. also results by satg. I and o-HOC_6H_4CHO in EtOH with HCl. $(PhCH_2)_2CO$ and 2-$HOC_{10}H_6CHO$ in EtOH, with either HCl or piperidine, give *2-benzylidene-3-phenyl-Δ^3-β-naphthapyran*, brilliant reddish orange, m. 145°; on being kept for several days in Me_2CO, the orange color disappears and an amorphous pale yellow solid, m. above 200°, seps. Using 2 mols. $HOC_{10}H_6CHO$, there results *3,3'-diphenyldi-β-naphthaspiropyran*, m. 248°, which forms a *monohydrate*, m. 248°, from Me_2CO. No color develops when heated in Ph_2O C. J. West

Flavanone glucosides. II. Constitution of naringenin. Yasuhiko Asahina and Mototaro Inubuse. Univ. Tokyo. *Ber.* **61B,** 1514-6(1928); cf. *C. A.* **22,** 2946.—Tutin found that eriodictyol, homoeriodictyol and hesperetin on complete methylation yield the same 3,4,2',4',6'-pentamethoxychalcone and, from analogy, assigned a tetrahydrohydroxychalcone structure to naringenin (I). A. and I., however, recently showed that sakuranetin and hesperitin are not chalcones but flavanones, energetic methylation (as well as acetylation) rupturing the hydropyrone ring with formation of chalcone derivs. They have now carried out similar expts. with I and found that with Ac_2O and a drop of concd. H_2SO_4 it gives a *tri-Ac deriv.* (II) which gives no color with $FeCl_3$ but a red color on reduction with Mg and HCl. On long heating with Ac_2O and NaOAc, however, I yields a *tetra-Ac deriv.* (III) which no longer gives a color on reduction. With CH_2N_2 I forms a di-Me ether identical with sakuretin mono-Me ether. I is therefore 5,7,4'-trihydroxyflavanone (cf. Shibata and Nagai, *C. A.* **19,** 3064, who found that the absorption spectrum of I agrees with that of a flavanone and not a chalcone deriv.). Frank's statement that I on catalytic reduction gives phloretin could not be verified. II, m. 53-5°. III, yellowish, m. 133-6°. C. A. R.

Some quinoline derivatives. R. Hupe and A. Schramme. Univ. Göttingen. *Z. physiol. Chem.* **177,** 315-20(1928).—New quinoline derivs. were prepd. for the purpose of testing their pharmacol. activity. *2-Quinolyl-β-ethylamine*, m. 174° (*HCl salt*, m. 212°; *picrate*, m. 209°), was obtained by hydrogenation of *2-quinolylacetaldoxime*, m. 201°, by means of H and Pt. Further reduction of the oxime by Na and EtOH yielded *py-tetrahydro-2-quinolyl-β-ethylamine*, b_{16} 188°; *di-HCl salt* m. 230°. *4-Amino-pyrogallol tri-Me ether* (*HCl salt*, m. 200°) was prepd. by $SnCl_2$ reduction of the corresponding NO_2 deriv., and, by treatment with $ClCH_2COCl$, converted into *4-chloroacetyl-aminopyrogallol tri-Me ether*, m. 85°. By the Skraup synthesis with glycerol and $PhNO_2$ this amine yielded *6,7,8-trimethoxyquinoline* m. 80° (*picrate*, m. 181°). The same

amine when refluxed with $(AcH)_3$ and HCl yielded *6,7,8-trimethoxyquinaldine*, m. 73°; *picrate*, m. 142°; *oxalate*, m. 148°; *chloral addn. product*, m. 114°. Condensation of the amine with $AcCO_2H$ and BzH yielded *trimethoxyatophan*, m. 174–5°. The physiol. properties of these derivs. are not stated. A. W. Dox

Modification of the Skraup synthesis of quinoline. Byron E. Cohn and R. G. Gustavson. Univ. of Denver. *J. Am. Chem. Soc.* **50,** 2709-11(1928).—The violence of the ordinary Skraup reaction is believed to be due to the sudden liberation of CH_2:CHCHO resulting from the action of H_2SO_4 upon $C_3H_5(OH)_3$; AcOH is therefore introduced to remove a large proportion of the $C_3H_5(OH)_3$ from the reaction sphere. The following reagents are placed in a l. flask in the order named: $PhNH_2$ 38 g., $PhNO_2$ 24 g., $C_3H_5(OH)_3$ 100 g., AcOH (80%) 60 cc., H_2SO_4 (95%) 54 cc., and the mixt. heated for 16 hrs.; yield, about 30 g. quinoline. This method eliminates the occasional violence of the ordinary Skraup reaction. The influence of the time of heating and of varying amts. of AcOH and of $C_3H_5(OH)_3$ is shown in curves. The concn. of the AcOH has no decided effect upon the yield of quinoline. C. J. West

Asymmetric nitrogen atom. LV. True autoracemization of optically active ammonium salts. E. Wedekind and G. L. Maiser. Forstl. Hochschule Hann-Münden. *Ber.* **61B,** 1364-75(1928); cf. *C. A.* **22,** 589.—Some yrs. ago E. and O. Wedekind succeeded in sepg. the *d*-bromocamphorsulfonate (I) of *N*-methylallyltetrahydroquinolinium (II) into fractions with different rotatory powers but it is not always possible to obtain optically active iodides (III) from these fractions and the question arose whether this might not be a case of true autoracemization. The expts. have now been repeated on a larger scale to test this point. The results of the resolution expts. were the same as before; mol. rotations of the active cation ranging from 202° to —157° were observed. Recrystn. of the extreme fractions did not increase the rotation but the *l*-salt was now obtained with $[M]_D$ as high as —160° as against a max. of —80.3° in the earlier work. Great caution had to be observed in the conversion of the I into the III by both the older method (pptn. in H_2O with KI) and the new method (treatment with NaI in Me_2CO, a solvent which had been found to have no racemizing action). The highest rotations obtained for the III were $[M]_D$ 28° and —27°; that these values are materially lower than the calcd is readily explained by the observations which were made on the influence of various solvents on the loss in rotation of the active **III.** Of the 5 solvents which could be used (H_2O, MeOH, EtOH, Me_2CO, $CHCl_3$) the 1st three produce a relatively rapid fall in rotation and the last two produce no change Especially noteworthy is the strong influence of H_2O and the slight influence of $CHCl_3$. Kinetic measurements gave for H_2O at 20° a monomol. reaction constant *k* of 0.00543, for EtOH 0.00643, for $CHCl_3$ 0.00131-0.00198; in Me_2CO no change in rotation was observed in 48 hrs. The velocity consts. in H_2O and EtOH show no drift whereas in $CHCl_3$ there is a distinct upward drift, as has been found in the inactivation of all NH_4 salts hitherto studied in $CHCl_3$ and other solvents with low dielec. consts. and which has been explained as due to decompn. through the presence of double moles in $CHCl_3$ The absence of a drift in H_2O and EtOH suggested that the inactivation of the **III** in these solvents does not depend on a reversible decompn but on a true stereochem. rearrangement. From the experience of W. and Paschke, decompn. can always be followed sharply by the change in cond. with time. The cond. of **III** in H_2O and EtOH remains const. whereas in $CHCl_3$ it decreases with the time, the velocity consts. of the decrease being of approx. the same magnitude as the consts. for the decrease in rotation and also showing an upward drift. Even though the decompn. velocity is somewhat less than with the typical asym. NH_4 salts which are inactivated in $CHCl_3$ by thermal dissocn., this might perhaps be considered contradictory to the W. and Paschke rule that quaternary NH_4 halides in $CHCl_3$ and other solvents with low dielec. consts. decomp. when there is present an aryl group together with a benzyl or allyl residue. The **III** contain no free Ph group, to be sure, but on the other hand the C_6H_6 nucleus is present as a component of the tetrahydroquinoline nucleus. If it be conceived that the ring in **III** is opened as shown in the formula

$$\begin{array}{lcl} C_6H_4 & : & CH_2.CH_2 \\ | & & | \\ \multicolumn{3}{l}{NMe(C_3H_5)I.CH_2} \end{array}$$

and that two H atoms are added the product will be *propylmethylallylphenylammonium iodide* (**IV**). **IV** was accordingly prepd. Its cond. distinctly decreased with a velocity const. of approx the same magnitude as that of the cond. decrease of **III** and showing the same upward drift, *i. e.*, ring formation in the cyclic NH_4 salts has no influence on the decompn tendency in $CHCl_3$. That the spontaneous decrease in rotation of the **III** in H_2O and EtOH is not due to a decompn. was confirmed in 2 other ways. (1) Alc. solns. of the inactive **III** were allowed to stand until, on the basis of the expts. with the active forms,

all rotation had disappeared and Et_2O was then added as long as a ppt. was formed; the wt. of this ppt. was practically the same as that of the original **III**, whereas if there had been a decompn. it should have weighed less because of the washing away of the decompn. products (tertiary base + alkyl halide). (2) The temp. coeff. (20–30°) of the velocity of decrease in rotation in alc. is 2.06, *i. e.*, materially smaller than the values (3.6–4.1) which had been found for the salts that decomp. The inactivation in H_2O and EtOH can therefore be only a true autoracemization (a stereochem. rearrangement of 1 isomer into its antipode until equil. is reached) analogous to the phenomena observed (in relatively only few cases) in the asym. C atom series. To explain the mechanism of such a process is even more difficult with the N than with the C compds. It is especially difficult to see why active asym. NH_4 salts of the type NabcdX, with individual radicals, show no autoracemization in H_2O and EtOH, whereas **III**, which, with 2 of the N valences in the ring, would be expected to be more stable, does. Of special interest is the fact that true autoracemization is dependent on the presence of ionizable halogen on the N; it has not been possible to obtain a cryst. salt of **II** with other inactive acids (HNO_3, H_2SO_4, $HClO_4$) than the halogen acids, but both the I in H_2O and mixts. of these with solns. of alkali nitrates and sulfates show no change in rotation with time while mixts. with alkali halide solns. do show a distinct decrease (*e. g.*, the velocity const. of this decrease at 25° on the addn. of 1 equiv. KI is 0.00118, is smaller for KBr and still smaller for KCl). **II** offers for the present the only known example of the phenomena described above; it has thus far not been possible to convert *N-ethyl-N-allyltetrahydroquinolinium* (V) through either the camphor- or bromocamphorsulfonate into well crystd. salts suitable for fractionation. The tetrahydroquinoline, m. 243°, was obtained almost quant. from quinoline and H at 200° under 30 atm. with Schroeter's Ni catalyst (the compn. of which is kept secret); the *N*-Me deriv., prepd. with MeI, b. 242–4°, and with CH_2:$CHCH_2I$ in alc. and a little Et_2O gives 80% inactive **III**, light yellow, decomps. 143°, cond. at 25° (concn. 1:250) in H_2O 0.000123, in EtOH 0.000321. *N-Methyl-N-ethyltetrahydroquinolinium iodide*, m. 174°, cond. at 25° in $CHCl_3$ (0.1080 g. in 25 cc.) 0.0003609, remaining const. for 24 hrs. *N*-Ethyltetrahydroquinoline (37 g. from 38.8 g. tetrahydroquinoline with EtI on the H_2O bath), b_{23} 140°, gave in 1 case with CH_2:$CHCH_2I$ in EtOH-Et_2O 2 *iodides* of **V**: the more difficultly sol. form, decomps. 136.0°, mol. wt. in freezing *p*-toluidine 352; and the more easily sol. form, m. 118°, mol. wt. 288–300; in subsequent expts. the 136° form could never again be obtained. C. A. R.

Certain new oxidation reactions of aldehydes. James B. Conant and John G. Aston. Harvard Univ. *J. Am. Chem. Soc.* **50**, 2783–98(1928).—Me_2CHCHO (10 g.) added to 115 g. $K_3Fe(CN)_6$ in 1 l. H_2O at 80° and then treated with 320 cc. *N* NaOH during 45 min., gives 27.5% of *2,2,5,5-tetramethyldihydropyrazine* (I), m. 83–4°, b. 160°; Br-H_2O gives a yellow ppt., $HgCl_2$ a white ppt. Reduction with Na and H_2O gives the piperazine, which gives with HCl and KNO_2 *dinitroso-2,2,5,5-tetramethylpiperazine*, m. 208–10°. In a more concd. soln. (0.28 *M*), there also results *2,2,5,5-tetramethyl-3,6-dicyanopiperazine*, m. 193–4.5°, also prepd. by passing HCN into 1% aq. I at 100°; *di-Na deriv.*, m. 178° (violent decompn.). No Me_2CHCO_2H is formed in this reaction. $MeCOCHMe_2$, under the same conditions, gives hexamethyldihydropyrazine (25% yield); the reaction involves the oxidation of the α-C atom and the gain of N from a fraction of the complex cyanide. At least 65% of the oxidizing agent was reduced to $K_4Fe(CN)_6$. AcH and alk. $K_3Fe(CN)_6$ yield no AcOH at 80°. The oxidation of Me_2CHCHO with $Ce(SO_4)_2$ at 80° in acid soln. yields Me_2CO and $Me_2C(OH)CHO$ as well as Me_2CHCO_2H; the same products are formed in acid soln. by $KMnO_4$ and $Co_2(SO_4)_3$. Chloranil and Pd yield $Me_2C(OH)CHO$. $K_2Cr_2O_7$ in acid soln. at 80° oxidizes Me_2CHCHO in the α-position, yielding Me_2CO to the extent of 40% in very dil. solns. The process of α-oxidation is favored by diln. PrCHO is also oxidized in the α-position, as shown by the formation of CO_2. $KMnO_4$ oxidizes AcH in acid soln. at 80°, yielding CO_2 as well as AcOH if precautions are taken to keep the reactants in very dil. soln. with excess of aldehyde. C. J. West

10-Chloro-5,10-dihydrophenarsazine and its derivatives. VI. Compounds containing two nitrogen and two arsenic atoms in six- and five-ringed systems. Charles S. Gibson and John D. A. Johnson. Univ. of London. *J. Chem. Soc.* **1928**, 2204–15; cf. *C. A.* **22**, 400.—Heating a mixt. of 3.45 g. $(p\text{-}H_2NC_6H_4)_2$, 11.3 g. $o\text{-}BrC_6H_4AsO(OH)_2$, 8.8 g. K_2CO_3, 40 cc. AmOH and a trace of Cu 5 hrs. gives *4,4'-bis(diphenylamine-2'-arsonic acid)*, does not m. 320°; reduction in a hot mixt. of EtOH and HCl contg. a trace of I with SO_2 gives *2,2'-bis-[10-chloro-5,10-dihydrophenarsazine]* (I), pale orange-yellow, which does not m. 325°, apparently identical with the compd. obtained by heating $(p\text{-}PhNHC_6H_4)_2$, $AsCl_3$ and $o\text{-}C_6H_4Cl_2$ for 5 hrs. (58% yield). Oxidation with

H_2O_2 in AcOH gives *2,2'-bis[phenarsazinic acid]*, amorphous; the *di-Na salt* was analyzed; the K, Mg, Ca, Ba, Hg, Ag and Cu salts were also prepd. From the NH_4OH soln. the acid ppts. on boiling. Oxidation with SO_2 in a mixt. of EtOH and HBr gives the *10-Br deriv.* (corresponding to I). *N,N'*-Di-*p*-tolylbenzidine gives 64% of *2,2'-bis[10-chloro-8-methyl-5,10-dihydrophenarsazine]*, orange-red; *10-Br deriv.*, red; *10-I deriv.*, purplish red. Oxidation gives *2,2'-bis[8-methylphenarsazinic acid]*, amorphous, does not m. 325°; *di-Na salt*, needles. *o*-$C_6H_4(NH_2)_2$ and *o*-$BrC_6H_4AsO(OH)_2$ give a crude product which could not be purified, so it was reduced with SO_2 and, as this product could not be purified, it was again oxidized with H_2O_2, purified through the Na salt and again reduced, giving *5,8-dichloro-13,14,5,8-tetrahydroisobenzarsazinephenarsazine* (II), dark brown, insol. in all the usual solvents and does not m. 320°. *m*-$C_6H_4(NH_2)_2$ and *o*-$BrC_6H_4AsO(OH)_2$ give 22% of *1,3-phenylenediaminodi-o-phenylarsonic acid*, distinguished from the corresponding ring acid by its ready soly. in a mixt. of HCl and EtOH; boiling with EtOH-HCl gives *12,14* (or *8,14*)*-dichloro-5,7,12,14* (or *5,13,8,14*)*-tetrahydrobenzarsazinephenarsazine* (III or IV), yellow prisms. *m*-$C_6H_4(NHPh)_2$ and $AsCl_3$ in *o*-$C_6H_4Cl_2$, boiled 5 hrs., give red prisms, which differ from the above, not only in color and cryst. form but in the fact that the former had a more pronounced effect on the mucous membranes than the latter. When these 2 di-Cl compds. were separately oxidized to the diarsonic acids and these acids separately reduced back to di-Cl compds., the latter had the same color (yellow) but different properties. The *5,7,12,14* (or *5,13,8,14*)*-benzarsazinicphenarsazinic acid* prepd. from either di-Cl compd., purified through the *Na salt*, appears to be the same product; various other salts were prepd. Reduction with SO_2 in EtOH-HBr gives the *12,14* (or *8,14*)*-di-Br deriv.*, deep yellow; the *di-I deriv.* is deep red. It was impossible to purify the product from *p*-$C_6H_4(NH_2)_2$. *p*-$C_6H_4(NHPh)_2$ and $AsCl_3$ give 49% of *7,14* (or *13,14*)*-dichloro-5,12,7,14* (or *5,8,13,14*)*-tetrahydrobenzarsazinephenarsazine*, orange-red, doubly refracting, prismatic needles; oxidation with H_2O_2 in AcOH suspension gives *5,12,7,14* (or *5,8,13,14*)*-benzarsazinicphenarsazinic acid*, plates, darkens slightly above 290° but does not m. 320°; *Na salt*. The *di-Br deriv.* forms deep red, doubly refracting, prismatic needles. The di-I deriv. could not be purified.

lin-(Benzo-*p*-thiazino)quinones. K. Fries, W. Pense and O. Peeters. Techn. Hochschule Braunschweig. *Ber.* **61B**, 1395–1402(1928); cf. *C. A.* **18**, 2521.—The following addns. are made to the earlier work: As had already been pointed out, the method for the prepn. of vat dyes with the skeleton of *lin*-dibenzo-*p*-thiazine can also be used for the prepn. of those dyes whose simplest representative is the dark blue *lin-di[benzo-p-thiazino]-p-quinone* (I); instead of using an arylaminochloro-α-naphthoquinone, a *N,N'*-diaryl-2,5-diamino-3,6-dichloro-*p*-quinone is treated with an alkali sulfide and the resulting dimercaptan (II), isolated as the di-Me ether (III), is oxidized to the I. Shibata has recently (*C. A.* **22**, 1585) obtained results which agree in most respects with those of K., P. and P. although they do not feel that his proof of the sulfide-like union of the S in the I (addn. of 1 atom O per atom S on oxidation with HNO_3 and regeneration of I from the $Na_2S_2O_4$ vat of the oxidation product) is conclusive; analogous reactions might take place if the I were a disulfide. Decisive evidence as to the nature of the S union in I is obtained by vigorous oxidation, which gives a *disulfone* (IV) and no SO_3H acid. IV has pronounced acid properties, forming a well-crystd. red *di-Na salt*. In agreement with the structure I is the formation of a di-Ac deriv. on acetylation and of a tetra-Ac deriv. on simultaneous reduction and acetylation. A method had already been devised for prepg. derivs. of *lin*-[benzonaphtho-*p*-thiazino]-5,10-quinone contg. an alkyl- or arylamino group in the *peri*-position to the keto-O atom and having a much greater affinity for animal fibers than the parent substance. This method, however,

did not prove to be adapted to the prepn. of the simple NH_2 deriv. **V**, which has now been prepd. from *5-nitro-2,3-dichloro-1,4-naphthoquinone* (**VI**) through the *2-mercapto-3-phenylamino deriv.* (**VII**). The acyl derivs. of **V** are vat dyes giving on wool stronger and faster colors than the free **V**. By treating the **VI** with other arylamines than $PhNH_2$ many derivs. of **V** can be obtained. The **VI** was prepd. by direct nitration of 2,3-dichloro-1,4-naphthoquinone, the chief product being the α-NO_2 compd., as shown by its prepn. from 1,5-$C_{10}H_6(NH_2)NO_2$. 2,5-Dianilino-3,6-di[methylmercapto]-1,4-quinone (**III**), prepd. in the same way as by Shibata, blue-black, m. 260°, gives with H_2O_2 in AcOH 2,5-dianilino-1,4-quinone instead of the disulfone, probably because of hydrolysis of the oxidation product. **I** does not m. 360°, carbonizes on higher heating, is repptd. unchanged by H_2O from the deep blue soln. in concd. H_2SO_4, is not attacked by alkalies even in alc., forms with alk. $Na_2S_2O_4$ a clear golden yellow vat; *di-Ac deriv.*, blue crystals with bronze luster. *Hydroquinone*, pptd. by SO_2 from the vat of **I**, faintly yellow, m. above 360°, rapidly changes back into **I** in the air; *tetra-Ac deriv.*, from **I** in boiling Ac_2O-NaOAc with Zn dust, almost colorless, m. 305°. **IV**, from **I** in concd. H_2SO_4 with H_2O_2, red-brown, m. above 360°, loses its H_2O of crystn. only at 120° *in vacuo*. *2,5-Dichloro-3,6-di[p-methoxyanilino]-1,4-quinone,* from chloranil and *p*-anisidine, red-brown leaflets with greenish black luster, m. 291°. *2',3',5',6'-Di[methoxy-2,3-benzo-p-thiazino]-1',4'-quinone* (**I** with $MeOC_6H_3$ instead of C_6H_4), blue, m. above 360°. *1-Keto-2,2,3,3,4-pentachloro-5-nitrotetralin* (50% from 1,5-$C_{10}H_6(NH_2)NO_2$ in AcOH-HCl with Cl), m. 159° (decompn.), sol. in concd. H_2SO_4 with brown-red color and liberation of HCl, in NaOH with red color (with decompn.), gives in AcOH with aq. $NaHSO_3$ at 80° 90% of *2,3,4-trichloro-5-nitro-1-hydroxynaphthalene*, greenish yellow, m. 208°, which is sol. in alkalies with red color, forms an *Ac deriv.*, m. 150°, and gives in fine suspension in cold AcOH with a little HNO_3 *1-hydroxy-2,3,4-trichloro-4,5-dinitronaphthalene 1,4-dihydride*, m. 85° (decompn.); this cannot be recrystd. without decompn., becomes yellow in the air in a few days, and changes on heating in AcOH, concd. H_2SO_4 and also neutral solvents into **VI**, light yellow, m. 176°, best obtained (40-5%) from the dichloronaphthoquinone in concd. H_2SO_4 with red fuming HNO_3 (d. 1.52) on a gently boiling water bath; **VI** yields with $PhNH_2$ *2-anilino-3-chloro-5(8)-nitro-1,4-naphthoquinone*, brown-red, m. 273°, converted in boiling alc. with aq. Na_2S into the dark violet **VI**, which, boiled 45 min. in $PhNO_2$, treated with $Na_2S_2O_4$ and repptd. with air, yields *9-amino[lin-(benzonaphtho)-p-thiazino]-5,10-quinone* (**V**), blue-black, m. 300°. The light yellow vat of **V** dyes wool brown-violet; the almost neutral golden yellow vat of the *Ac deriv.* (green crystals with black luster, m. 300°) dyes wool a golden green. *2,3-Dichloro-5-amino-1,4-naphthoquinone*, from **VI** with $SnCl_2$-HCl and subsequent treatment of the resulting *hydroquinone-HCl* in H_2O with $FeCl_3$, dark violet, m. 220°, sol. without color in concd. H_2SO_4, repptd. by H_2O, gives with $PhNH_2$ *2-anilino-3-chloro-5(8)-amino-1,4-naphthoquinone*, dark brown, m. 210°, whose vat dyes wool a light red.

Dihydroxy- and dichloroketohexahydrotriazines. John B. Ekeley and Adrian A. O'Kelly. Univ. of Colorado. *J. Am. Chem. Soc.* **50**, 2731-3(1928).—$H_2NCONHNH_2$.HCl and the $NaHSO_3$ addn. products of $(CHO)_2$, AcCHO and aliphatic 1,2-diketones form dihydroxyketohexahydro-α-triazines, yielding with PCl_5 di-Cl derivs. They do not melt but begin to decomp. at definite temps. They are decompd. on boiling with strong acids but in the cold yield salts; they are stable against hot alkalies The following *$NaHSO_3$ addn. products* were obtained by evapg. aq. solns.: *diacetyl*, decomps. 145-55°; *propionylacetyl*, decomps. 135-50°; *butyrylacetyl*, decomps. 130-40°; *valerylacetyl*, decomps. 100-10°; *caproylacetyl*, decomps. 95-100°. *Dihydroxyketohexahydro-α-triazine*, $C_3H_7N_3O_3$, decomps. 265-70° (the following temps. are all decompn. temps.)(*di-Cl deriv.*, 265-70°); *Me deriv.*, 250-5° (*di-Cl deriv.*, 260-70°); *di-Me deriv.*, 240-5° (*di-Cl deriv.*, 250-60°); *MeEt deriv.*, 230-5° (*di-Cl deriv.*, 240-5°); *MePr deriv.*, 240-5° (*di-Cl deriv.*, 230-5°); *MeBu deriv.*, 230-5°; *MeAm deriv.*, 100-5°.

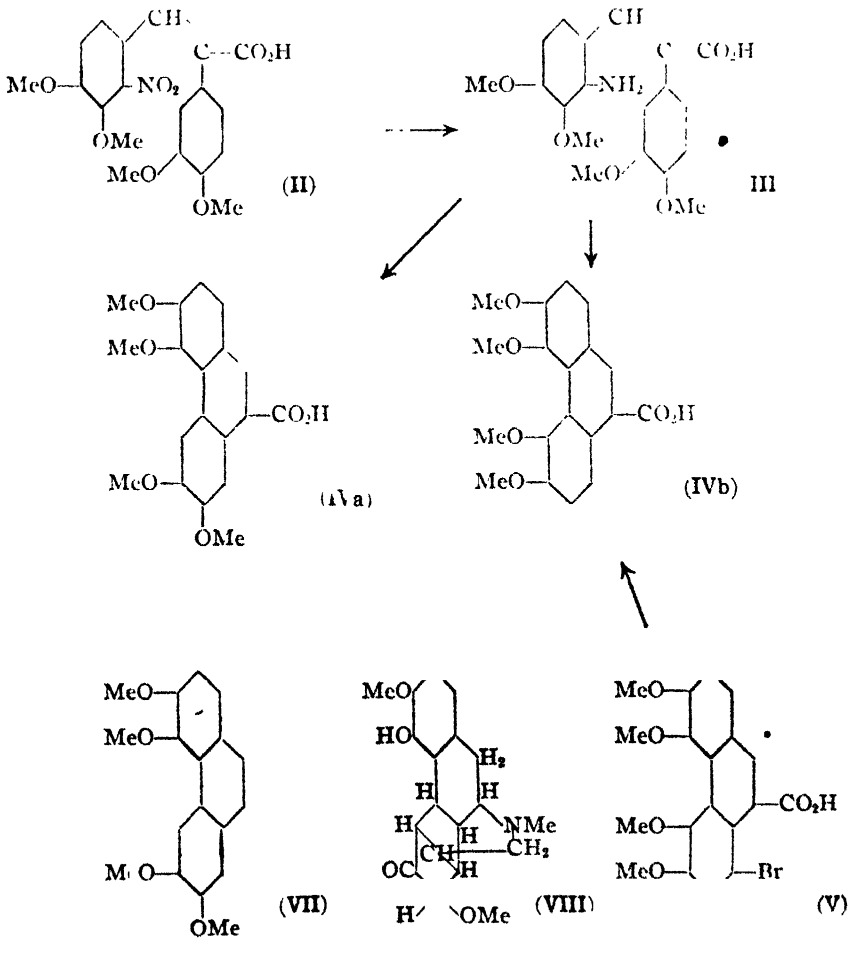
Synthetical experiments on the aporphine alkaloids. IV. A synthesis of morphothebaine dimethyl ether. John M. Gulland and Robert D. Haworth. Univ. of Durham. *J. Chem. Soc.* **1928**, 2083-8; cf. *C. A.* **22**, 3665.—2,3,4-$O_2N(MeO)_2C_6H_2CH_2COCl$ and 3-$MeOC_6H_4CH_2CH_2NH_2$ in C_6H_6 give *2'-nitro-3',4'-dimethoxyphenylaceto-*

β-3-methoxyphenylethylamide, m. 107–8°; with PCl_5 in $CHCl_3$ for 36 hrs. at room temp. this gives *2′-nitro-6,3′,4′-trimethoxy-1-benzyl-3,4-dihydroxyisoquinoline* (I), pale yellow, m. 121–3°; *HCl salt*, m. 217–8°; *sulfate*, m. 237° (decompn.); *methiodide* (II), yellow, m. 220° (decompn.); this is unusually stable to alk. fission and attempts to decomp. it with NaOH gave only *2′-nitro-6,3′,4′-trimethoxy-1-benzylidene-2-methyltetrahydroisoquinoline*, red tablets or yellow prisms, m. 108–9°, which gives with NaI **II**. The acid mother liquor from **I**, rendered alk. with NH_3, gives *2′-nitro-6,3′,4′-trimethoxy-1-benzoyl-3,4-dihydroisoquinoline*, faintly yellow, m. 164° (decompn.); *oxime*, amorphous. Reduction of **II** with HCl and Zn gives *2′-amino-6,3′,4′-trimethoxy-1-benzyl-2-methyltetrahydroisoquinoline*, pale yellow oil, analyzed as the *di-HCl salt*, which crysts. with 1 mol. $CHCl_3$, m. 155°; the diazo soln. with β-$C_{10}H_7OH$ gives a scarlet dye, giving a reddish purple color with concd. H_2SO_4. Reduction of the diazo soln. in H_2SO_4-MeOH gives *dl-3,4,6-trimethoxyaporphine*, pale yellow oil, whose *HI salt* m. 227° (decompn.). The base is resolved by *d*-tartaric acid and the *l*-base is identical with the natural product; the *methiodide*, m. 195°, $[\alpha]_D$ −87.1° (c 0.448, H_2O). The *d*-base gives a *H l-* (H2O, c 0.821); the oily *d*-base has $[\alpha]_D$ 174.2° ($CHCl_3$). C. J. West

Alkaloids of sinomenium and cocculus. XI. Constitution of sinomenine. 4. H. Kondo and E. Ochiai. Tokyo Imp Univ. *J. Pharm. Soc Japan* No. **539**, 17–24 (1927).—The constitution of sinomenine (I) was tentatively proposed in the last paper (*J. Pharm. Soc. Japan* No. **538**), but the position of the second MeO group still remained



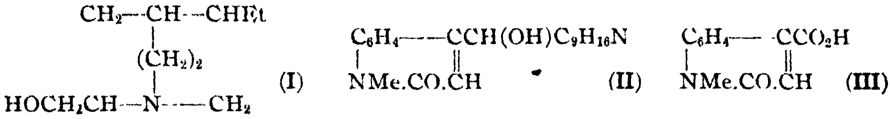
(II) III (IVa) (IVb) (VII) (VIII) (V)

uncertain. By the following syntheses this point has been clarified. Condensation of *v-o*-nitroveratric aldehyde and homoveratric acid by Ac_2O gave *α-(3,4-dimethoxyphenyl) 2-nitro-3,4-dimethoxycinnamic acid* (II) m. 191–2°. Reduction of II with $FeSO_4$ and NH_4OH gave *α-(3,4-dimethoxyphenyl)-2-amino,-3,4-dimethoxycinnamic acid* (III), m. 146°. Diazotization of III by Pchorr's method resulted in a ring closure and gave 2 forms of *tetramethoxyphenanthrene carboxylic acid*, one form (IVa), needles, m. 210°, and the other (IVb), six-sided platelets, m. 232–4°. In order to ascertain the structure of each, the above synthesis was repeated with 6-bromo-3,4-dimethoxyphenylacetic acid in place of homoveratric acid. The resulting *α-(3,4-dimethoxy-6-bromophenyl)-2-nitro-3,4-dimethoxycinnamic acid* was reduced to the corresponding *amino compd.*, m. 187°. The latter was then converted to *3,4,5,6-tetramethoxy-8-bromophenanthrene-9-carboxylic acid* (V), m. 187–8 (decompn.). Removal of Br from V by boiling with Zn-Cu in EtOH-NaOH gave *3,4,5,6-tetramethoxyphenanthrene-9-carboxylic acid* (VI), m. 234°, which was identical to IVb. Hence IVa should have the structure of *3,4,6,7-tetramethoxyphenanthrene-9-carboxylic acid.* Heating of IVa with glacial AcOH for 20 hrs. at 250–60°, gave *3,4,6,7-tetramethoxyphenanthrene* (VII) m. 124–5°. *Picrate* m. 123–5°. VII was found identical to Goto's (*Jour. Agr. Chem. Japan* [2], **2,** 17) dimethylsinomenol (tetramethoxyphenanthrene) obtained by KOH fusion of sinomenine Me ether. These facts show that the second MeO group is located at position 7 instead of at 5 and I is 7-methoxythebainone (VIII). NAO UYEI

Amine oxides of alkaloids. V. *N*-Oxides of ψ-tropine and of tropacocaine. MAX POLONOVSKI AND MICHEL POLONOVSKI. *Bull. soc. chim.* **43,** 364–7(1928); cf. *C. A.* **22,** 1592.—Tropacocaine, m. 49°, when treated with H_2O_2 in acetone gives a *N-oxide*, $C_{15}H_{19}O_3N$, m. 152–3° (*hydrochloride*, m. 200°), which on reduction with SO_2 or nascent H yields the original base, and on hydrolysis with concd. HCl the *N-oxide* of ψ-tropine, m. 229° [*hydrochloride*, m. 286°; *picrate*, m. 257° (decompn.)]. With Ac_2O the *N*-oxide of tropacocaine yields *O-benzoyl-N-acetylnor-ψ-tropine*, hydrolyzed by *N* alc. KOH to *N-acetylnor-ψ-tropine*, m. 127°, or by 20% H_2SO_4 or concd. KOH to nor-ψ-tropine. The latter is also obtained by hydrolysis of the *diacetylnor-ψ-tropine* formed when the *N*-oxide of ψ-tropine is similarly treated with Ac_2O B. C. A.

Alkaloids of lupines. CLEMENS SCHÖPF, OTTO THOMÄ, ERICH SCHMIDT AND WILLY BRAUN. Univ. of Freiburg i. Br. *Ann.* **465,** 97–147(1928).—*I. Isomeric lupinic esters and lupinans.*—In the oxidation of lupinine to lupinic acid (I) with CrO_3 in H_2SO_4, according to Willstätter and Fourneau (*Ber.* **35,** 1917(1902)), it is necessary to use not more than the calcd. amt. of CrO_3; esterification gives a Me ester, (II), b_{10} 120–2°, $[\alpha]_D^{21}$ —19.4°; other prepns. showed values from 5.8° to —19.4°, without any apparent reason for the variation. II, boiled with 4 parts concd. HCl 3–4 hrs., gives the (−)−I HCl salt (III), m. 275°, $[\alpha]_D^{21}$ —13.1°; the prepns. with lower *l*-rotatory values gave a more easily sol. HCl salt, which could not be crystd. III is changed into a resin by $SOCl_2$; PCl_5 in AcCl does not react with III; but in BzCl, PCl_5 at 100°, followed by esterification, gives 65% of *Me* (+)−*epilupinate* (IV), b_{11} 126°, $[\alpha]_D^{16}$ 54.8° (0.1135 g. in 2.5 cc. MeOH), after purification through the *picrate*, m. 185°, $[\alpha]_D^{17}$ 61.8° (0.1596 g. in 2.5 cc. $CHCl_3$). A sample of II with $[\alpha]_D^{18}$ —3.5° (78.6% of pure II) warmed on the H_2O bath with MeONa 1 hr., gives a mixt. contg. 84.8% of IV. II, heated with MeOH satd. with NH_3 at 150° for 8 hrs., gives a mixt. of IV and *Me* (±)−*epilupinate*, b_{11} 128–30°, whose *picrate*, m. 208°, is optically inactive. III in $CHCl_3$, with NH_3 for about 2 hrs., gives (+)—*epilupinic amide*, sublimes at 11 mm. and 250° and m. 228°, $[\alpha]_D^{18}$ 41.3° (0.1137 g. in 2 cc. MeOH). In another expt., in which the $CHCl_3$ apparently contained $POCl_3$, there resulted the *nitrile*, b_{11} 120°, analyzed as the *HCl salt;* $[\alpha]_D^{20}$ 52.9° (0.1730 g. in 10 cc. $CHCl_3$). Anhydrolupinine (V), prepd. according to W. and F., gives quant. in Et_2O the *picrate*, m. 94°, optically inactive. Of the various oxidation methods tried, only $KMnO_4$ in 2 *N* H_2SO_4 gave a definite product; this is the corresponding *glycol*, $C_{10}H_{19}O_2N$, b_{11} 165–7°. Reduction of V by H with Pd-$CaCO_3$ gives a mixt. of inactive α- and β-lupinane, sepd. by fractional crystn. of the picrates; the α-picrate m. 187°; the *β-picrate*, 163°; some lupinine picrate, m. 163°, is also formed. *II. Possible relations between lupinine and the cinchona alkaloids.*—A consideration of the known properties and behavior of lupinine suggests the formula (I); if this be true, then it corresponds to the 2nd half of the reduced cinchona alkaloids. In an attempt to establish such a relation, *dihydrocinchonine-MeI.HI*, yellow, m. 242–3°, was prepd.; oxidation with $K_3Fe(CN)_6$ gave the *quinolone* (II), $C_{20}H_{26}O_2N_2$, m. 213–4°, whose HCl salt m. 301°; further oxidation of II gives the *compd.* $C_{11}H_9O_3N$ (III), m. 246–7°, and cincholoipone, whose *Me ester* (IV) b_{12} 122–4°. *Dihydrocupreine-HI*, m. 241° (decompn.)

yields a *methiodide*, yellow, m. 245–6°; after removal of the I with AgOAc, oxidation gave **IV** as the only amino acid. *Dihydrodesoxycinchonine*, m 73–4°, by the catalytic reduction of desoxycinchonine or cinchene; *HI salt*, m. 230–1° (decompn.); *picrate*, m. 178–9°; *HI methiodide*, analyzed as the *dipicrate*, m. 170–1°; the free compd. is very unstable and quickly changes into an Et_2O-insol. resin; oxidation gives *N*-methyl-γ-quinoline, whose *picrate* m. 229°. Since an acid corresponding to I could not be obtained



(I) (II) (III)

in this way, an effort was made to split off CO_2 from lupinic acid; heating over a free flame or distn. of the Ca salt did not give the desired result. The reaction of the ester with PhMgBr was then investigated; the 1st product of the reaction is the *compd.* $C_9H_{16}NC(OH)Ph_2$, m. 170 1°, $[\alpha]_D^{21}$ 79.2°, stable towards CrO_3 and $KMnO_4$; HBr salt, m. 205°; the 2nd product is a ketone, $C_9H_{16}NBz$, yellow oil, b_1 126–8°, whose *picrate* m. 185°, $[\alpha]_D^{21}$ 38.5° ($CHCl_3$); a methiodide or oxime could not be prepd. These results indicate that the formula I is very improbable for lupinine; the suggestion is made that it may consist of 2 isoprene residues, as sparteine consists of 3 such residues. *III Sparteine.*—Oxysparteine (I) (Ahrens, *Ber.* **38,** 3268(1905)) is unchanged by excess Ac_2O or by Na and EtOH or AmOH; oxidation with H_2O_2 gives, after 4 months, the *N-oxide*, hygroscopic, m. about 220°, analyzed as the *picrate*, m. 221°; SO_2 reduces it to I. I gives a mixt. of 2 methiodides, from which the α-deriv. (II) is sepd. by $CHCl_3$-AcOEt, m. 243–4°, $[\alpha]_D^{18}$ −22.7°; the mother liquor gives the β-deriv., m. 234°, $[\alpha]_D^{18}$ −47.7°. II, transformed into the quaternary base, treated with Ag_2O in a N atm. and distd. in N, gives 45–55% of *α-des-N-methylsparteine* (III) (purified through the $HgCl_2$ compd., m 270 1°), b_{10} 172.5–3°; the mother liquor from the $HgCl_2$ compd. of III gives an isomeric *base*, $C_{16}H_{28}N_2$, b_{10} 160–1° ($HgCl_2$ compd., m. 182–5° (decompn.); *di-HI salt*, m. 223–5° (decompn.), $[\alpha]_D^{18}$ −37.5°). The 3rd product isolated is the *compd.* $C_{16}H_{30}ON_2$, b_{10} 183 9°, $[\alpha]_D^{19}$ 16.0°; $HgCl_2$ complex, m. 154 6°), does not give a salt with HI. The homogeneity of III was shown by the quant. formation of the di-HI salt, m. 236–7°. Crystn. from EtOH gives a *compd.* $C_{16}H_{28}N_2.3HI$ (IV), m. 206–7°, $[\alpha]_D^{19}$ 19 5°; soln. in H_2O and addn. of NaOH to alk. reaction splits off HI, giving the *compd.* $C_{16}H_{28}N_2.2HI$, m. 182 4°, $[\alpha]_D^{18}$ 41.7°; this does not give an Et_2O-sol. base on addn. of NaOH. From the mother liquor of IV there is isolated the *compd.* $C_{16}H_{28}N_2.HI.H_2O$, m. 206 8° (decompn.), $[\alpha]_D^{18}$ −13 3°. III and MeI give a mixt. of the monomethiodide, m. 239°, crystg. with 1 H_2O, and a *dimethiodide*, m. 266° (decompn.). Catalytic reduction of III gives a *dihydro deriv.*, m. 64°; *di-HI salt*, m. 267–8°. A cryst. methiodide could not be obtained. III and Br in $CHCl_3$ give a *dibromide*, whose *perchlorate* m. 267°. Oxidation of III with $KMnO_4$ (cooling in solid CO_2) gives the *glycol*, $C_{16}H_{30}O_2N_2$, m 200°. C. J. West

The identity of yohimbine and quebrachine. Raymond-Hamet. *Compt. rend.* **187,** 142 5(1928).—The presence of the same alkaloid in plants belonging to different botanical families is exceptional. Hence it is of interest to ascertain, as Fourneau and Page accept, whether yohimbine discovered by Spiegel in the corticle of *Pauingstalia Johimbine* (K. Sche) *Pierre* of the family of Rubicae is identical with quebrachine, first isolated by Hesse from the corticle of the white *Aspidosperma Quebracho* Schletch. of the family of Apocynacae, particularly as serious objections, which are mentioned in the paper, have been raised to this conclusion. Chem. pure quebrachine does not differ at all from pure yohimbine and microanalysis gives practically identical figures: calcd. for $C_{21}H_{26}N_2O_3$, C 71 15, H 7.40%; found for yohimbine 71.28, 7.54; for quebrachine 71.02, 7.46. Yohimbic and quebrachic acids have the same m. p., 259 60°. The rotary power in pyridine is 135.9°, and 136.7°, resp. In pyridine, yohimbine and quebrachine recrystd. from 50% MeOH have the same rotary power of 102.7°. The Et esters solidify at 189–90° and in abs. EtOH the rotary powers are practically identical—54.3° and 53.5°, resp. The rotary power in abs. EtOH is 48.1 for the yohimbate and 47.8 for the quebrachate. Physiologically the lethal doses of the HCl salts for a guinea pig are the same. Finally both possess the property of paralyzing the sympathetic nervous system so that the identity of the 2 substances is established. S. L. B. E.

Problem of the constitution of carotin. L. Zechmeister and L. v. Cholnoky. Univ. Pécs in Ungarn. *Ber.* **61B,** 1534–9(1928).—It was shown recently that carotin

(I) on catalytic hydrogenation in cyclohexane with Pt smoothly takes up 11 mols. H_2 with formation of a colorless compd. $C_{40}H_{78}$ very similar in properties to the higher members of the paraffin series (*C. A.* **22**, 2169). By taking samples of the substance during the hydrogenation and comparing them colorimetrically with the original I it has now been found that at least 2 or possibly 3 of the double bonds take no part in the production of the color of I and are satd. only towards the last, when the others have almost completely disappeared. During the absorption of the first 6-7 mols. H_2 the color intensity decreases proportionately to the quantity of H_2 absorbed, the curve representing the decrease in color intensity plotted against the H_2 absorbed following a straight line which, if prolonged, would cut the axis of abscissae at 8 mols. H_2. It is natural to assume that these color-producing double bonds are conjugated; that I contains many conjugated double bonds is also concluded by Pummerer and Rebmann from their absorption measurements (*C. A.* **22**, 2950). The partially hydrogenated compd. has the same spectrum as I itself, *i. e.*, it consists of a mixt. of the colorless compd. and unchanged I; there are no colored intermediate products. The conclusion that, along with the 8 conjugated olefinic double bonds, there are 3 double bonds of another kind, also agrees with P. and R.'s observations on the behavior of I towards ClI. Like Karrer and Salomon's perhydro-γ-crocetin (*C. A.* **22**, 2949), perhydrocarotin is optically inactive. Mol. wt. detns. on I in freezing C_6H_6 and in camphor gave 492 (av. of 6 detns. ranging from 447 to 516), on perhydrocarotin in freezing C_6H_6 593, 587, 593, thus confirming the Willstätter and Mieg C_{40}-formula. C. A. R.

Addendum to our paper on bromoporphyrin I and tetramethylhematoporphyrin iron salt. HANS FISCHER AND G. HUMMEL. Tech. Hochschule Munich. *Z. physiol. Chem.* **177**, 321(1928); cf. *C. A.* **22**, 1163, 1979.—Bromoporphyrin I is shown to be identical with dibromodeuteroporphyrin ester. A. W. DOX

The bile acids. XXI. MARTIN SCHENCK AND HENRY KIRCHHOF. Univ. Leipzig. *Z. physiol. Chem.* **177**, 280-94(1928).—The blue nitroso derivs. prepd. from bilianic acid dioxime by treatment with HNO_3 and by rearrangement through the action of concd. H_2SO_4, resp. (*C. A.* **22**, 3168), were previously thought to contain a bridged linkage. A double bond is now believed to represent the more probable structure in view of the behavior of these substances toward Zn dust and AcOH. The 1st ($C_{24}H_{33}NO_8$) adds 2H and yields a product which m. 240-2° (decompn.). Heated with HCl this decomps into bilianic acid and NH_2OH, whereas HNO_3 oxidizes it back to the original blue NO deriv. The 2nd NO deriv., ($C_{24}H_{34}N_2O_8$), which differs from the 1st in that an NH group has been inserted between the CH_2 and CO of ring II, undergoes reduction to the isodioxime of bilianic acid (I), and HNO_3 converts it back to the original blue NO deriv. Hydrolysis of I by 20% HCl yields NH_2OH and a bilianic acid monoisoxime, $C_{24}H_{35}NO_8$, which occurs in 2 modifications, m. 200-5° and 260°. Blue NO derivs may also be obtained from the oximes of isobilianic, reductodehydrocholic and dehydrocholic acids, but not from those of desoxybilianic, isodesoxybilianic or dehydrodesoxycholic acids. A. W. DOX

Cholesterol. IV. Different methods of oxidation. E. MONTIGNIE. *Bull. soc. chim.* [iv], **43**, 360-4(1928).—Oxidation of cholesterol in AcOH at 70° with an equal wt. of CrO_3 (cf. Mauthner and Suida, *Monatsh.* **17**, 29-49(1896)) affords a ketone and 2 ill-defined acids; with excess of CrO_3 complete oxidation to CO_2 and water takes place, while with smaller quantities of CrO_3 oxycholestenone, m. 122-3°, is obtained. HIO_3, alone or in presence of KOH, $K_3Fe(CN)_6$, alone or in presence of alkali, and $Na_2S_2O_8$, alone or in presence of $AgNO_3$, are without action on cholesterol. $KClO_3$ and HCl afford a mixt. of chlorinated compds. contg. a ketonic compd., since the product reacts with semicarbazide, giving a semicarbazone, and with PCl_5 in $CHCl_3$, giving an uncrystallizable compd. from which Cl is eliminated on oxidation. In view of these and earlier results (*C. A.* **21**, 2477, 3615; Windaus, *C. A.* **7**, 2566, 3503; **8**, 2385; **9**, 2246) it is concluded that cholesterol contains a ring system composed of hydrogenated benzene rings and that oxidation is unlikely to yield further pos. information as to its constitution. B. C. A

Ultra-violet irradiation of dehydroergosterol. A. WINDAUS AND O. LINSERT. Univ. Göttingen. *Ann.* **465**, 148-66(1928).—Ergosterol (I), when irradiated with ultraviolet light, is changed into a compd. or mixt. of compds. (II) of high antirachitic activity; this change is accompanied by a loss in the capacity to form an insol. ppt. with digitonin, a change in the optical activity from about —100° to 15° in 45 hrs., a change in the ultra-violet absorption spectra and an increase in soly. These changes are not due to a polymerization, since both I and II have the normal mol. wt. Both products contain 1 free HO group (reaction with MeMgI); titration with BzO_2H and catalytic reduction indicate that the no. of double bonds is not changed during the irradiation.

The exact nature of the activated product was not detd because the product could not be readily crystd. Therefore a no. of esters and other derivs. have been irradiated; the best results were obtained with *dehydroergosterol* (III). Reduction of I peroxide with Zn and 10% EtOH-KOH gives an *alc.*, $C_{27}H_{44}O_3$, m. 227° (decompn.), $[\alpha]_D^{21}$ —121.6° distn. at 0.5 mm. and 230° gives III, also obtained by heating I and $(AcO)_2Hg$ in EtOH for 40 min., m. 146°, $[\alpha]_D^{20}$ 149.2°; the air-dry product apparently contains 1 H_2O, that dried at 80° in a high vacuum, between 0.25 and 0.5 mol. H_2O; III is quant. pptd. by digitonin. *Acetate* (IV), m. 146°, $[\alpha]_D^{18}$ 193.4°. *Phenylurethan*, m. 161–2°, $[\alpha]_D^{16}$ 202°. Reduction of IV gave γ-ergostanol (satn. of 4 double bonds); in 1 expt. only 3 were satd., giving α-ergostenol. Irradiation in EtOH with eosin gives 30% of the *peroxide* of III, m. 158°. 1 part III and 1 part eosin in EtOH, exposed to sunlight, give 25% of *dehydroergopinacol*, m. 196° (decompn.). Irradiation of IV with a Hg vapor lamp gives 30–40% of cryst material, which consists of an *acetate*, m. 178°, of an alc., m. 175° (not further investigated), and an *acetate* (V), which on sapon. gives the *alc.*, $C_{27}H_{40}O$, m. 134°, $[\alpha]_D^{20}$ 119.5°, which decomps. on standing a few days; it gives no ppt. with digitonin and is not antirachitic; Ac_2O gives V, m. 126–7°, $[\alpha]_D^{16}$ 87.0°, which takes up 4 mols. H, but the reduction product could not be obtained cryst. C. J. WEST

SMITH, STANLEY F.: **Aids to Organic Chemistry.** London: Bailliere. 114 pp. 3s. net.

Metallo-organic compounds. STANDARD DEVELOPMENT COMPANY. Fr. 635,354, May 31, 1927. Alkyl compds. of metals of the second sub-group of the fourth periodic group are made by alloying the metal with an alkali metal, powdering the alloy and heating it to 40–70° with a liquid hydrocarbon in which the alkylating agent is dissolved and sepg. the products. An example of the prepn. of $PbEt_4$ is given.

Catalysts for organic synthesis. E. I. DU PONT DE NEMOURS AND CO. Fr. 635,777, June 10, 1927. Catalysts for the synthesis of org. compds. are made by heating to redness mixts. or compds. contg. sexivalent Cr and one or more of the metals, Zn, Cu, Cd, Mg, Mn, Ag and Fe, to form Cr salts contg. tervalent Cr.

Catalytic producton of organic compounds. I. G. FARBENIND. A.-G. Fr. 635,950, June 14, 1927. Contact masses which contain, apart from Cu, Ag, Au, Zn or their mixts. or alloys, other elements, particularly those of the Fe group or their compds., in small proportions and in the absence of supports which are bad conductors of heat, are used for the prepn. of hydrocarbons and org. O compds. from H and oxides of C. Catalysts contg. Cd or Tl or their compds. or mixts., and one or more metals of the Fe group or

their compds. may also be used. In examples, water gas is passed over a mixt. of oxides of Cu and Co, or over oxides of Cu, Fe and Zr. CO and H are passed over oxides of Cu, Ag and Co and CrO_3. Water gas is passed over a dried ppt. of carbonates of Fe, Cd and Cu, or over ferrocyanides of Cd and Cu.

Catalytic dehydrogenation. MARTIN LUTHER, KURT PIEROH and ERICH KRANEPUHL (to I. G. Farbenind. A.-G.). U. S. 1,684,634, Sept. 18. See Brit. 263,877 (*C. A.* **22,** 92).

Purifying catalytic products or other oxygen-containing organic compounds. OTTO SCHMIDT, KARL SEYDEL and ALBERT FELLER (to I. G Farbenind. A.-G.). U. S. 1,684,640, Sept. 18. Mixts. of alcs., aldehydes, ketones and esters or other O-contg. compds. of a higher order than MeOH such as may be obtained by the catalytic hydrogenation of oxides of C are treated in the vapor phase with H at a temp. of at least 50° (but below the temp. at which decompn. of the org. compds. would begin) in the presence of a hydrogenating catalyst such as a Ni-Cu or Ni-Al catalyst. This treatment serves to improve the color and odor of the material.

Catalytic oxidation of anthracene. ALPHONS O. JAEGER (to Selden Co.). U. S. 1,685,635, Sept. 25. In order to produce anthraquinone, vapors of anthracene-contg. material mixed with an oxidizing gas such as air are caused to react in the presence of a catalyst contg. a zeolite, *e. g.*, zeolitic material contg. combined V.

Transformation of paraffins into olefins and other more condensed hydrocarbons. LE PÉTROLE SYNTHÉTIQUE. Fr 32,570, Nov. 24, 1926 Addn to 610,543 The method of Fr. 610,543 is improved by using a vacuum reaching 40 to 50 cm. of Hg.

Decomposition of hydrocarbons. I. G. FARBENIND. A.-G. Fr. 635,889, June 13, 1927. Olefins or diolefins are prepd. by heating to a high temp hydrocarbons as vapors, with or without other gases, and in the presence of contact substances which contain difficultly reducible metallic oxides or mixts or compds of such oxides among themselves, such as oxides of Ca, Sr, Ba, Mg, Be, Zr, W, Mo, U, or aluminates of Ca or Zn or vanadates, chromates, tungstates of Ca, Zn, or Al In examples, tetrahydrobenzene is passed at a temp of 625° over CaO, whereby butadiene is obtained If the oxide is replaced by the aluminate ethylene and butadiene are produced. β Butylene is passed over Si vanadate, butadiene being formed.

Carbohydrate derivatives. WM. HARRISON. U. S. 1,684,732, Sept 18. Stable or permanent carbohydrate derivs. contg. combined N in the form of an amido or imido group or nitrile group are obtained by oxidation of a mixt of a colloidal carbohydrate compd. or compds. contg. the CSS group (such as viscose or starch xanthogenate) and NH_3 or a deriv. of NH_3 such as methylamine, ethylamine, aniline, urea, toluidine, benzylamine, naphthylamine, aminophenols, ethylenediamine, benzidine, diaminodiphenyl methane or phenylhydrazine (preferably an org deriv. of NH_3 in which at least one H atom is free). As oxidizing agents there may be used dichromates, chlorates, hypochlorites, peroxides, ferricyanides, HNO_2, SO_2, ferric salts, cupric salts and atm air or O with or without oxidizing catalysts or O carriers such as oxides and salts of Cu, Co, Fe, Mn and Ni or electrolytic oxidation may be employed. The compds formed are derivs. of diimido carboxylic disulfide of the general formula $RN{:}\underset{OR'}{\underset{|}{C}}{-}S{-}S{-}\underset{OR'}{\underset{|}{C}}{:}NR$, in which R represents H or the radicle attached to the N atom in the NH_3 deriv employed as a starting material and R′ represents the residue of cellulose, starch or other colloidal carbohydrate. Derivs. from cellulose and NH_3, viscose and aniline and some similar derivs. are described. The reactions may be carried out in alk., neutral or faintly acid mediums but not in a soln of such acidity as would decompose the carbohydrate CSS compds. When the reaction is carried out at an elevated temp such as at the b. p of water in an alk. medium other compds. are formed among which appear to be derivs. of benzothiazole of the general formula $C_6H_4{<}^{S}_{N}{>}C{-}OR'$ in which R′ represents a residue of cellulose, starch or other colloidal carbohydrate. The products are suitable for the manuf. of films, filaments, filling materials and the like. Some of them may be dissolved with caustic alkali and pptd. by neutralizing the alkali. Products which are not sol. in caustic alkali may be dissolved by other solvents such as $ZnCl_2$, H_2SO_4 and ammoniacal Cu-contg. solns. Cf *C. A.* **22,** 164.

Acetylating carbohydrates. EDMUND B. MIDDLETON (to E. I. Du Pont de Nemours & Co.). U. S. 1,685,220, Sept. 25. In producing cellulose acetate or similar products ketene is brought into contact with the carbohydrate suspended in glacial HOAc contg. H_2SO_4 or other suitable liquid medium.

Concentrating lower aliphatic acids. BRITISH CELANESE, LTD. AND W. BADER. Brit. 284,582, July 20, 1926. Esters of lower aliphatic acids such as MeOAc are heated with sapong. agents such as H_2SO_4, H_3PO_4 or $H_4P_2O_7$ in the presence of only approx. the quantity of water theoretically required. The materials may be brought into contact counter-currentwise.

Concentration of lower fatty acids. HENRY DREYFUS. Fr. 635,219, May 30, 1927. Lower fatty acids, particularly AcOH, are extd. from aq. solns. by a mixt. of a solvent for the acid and a hydrocarbon, such as 70 parts of Et_2O and 30 parts of petroleum ether b. about 40°. A counter-current process may be used and the extg. mixt. may be in vapor form.

Halides of aromatic oxamic acids. JOSEF HALLER (to Grasselli Dyestuffs Corp.). U. S. 1,685,698, Sept. 25. An oxalyl halide such as oxalyl chloride is caused to react upon a salt of a primary aromatic amine such as aniline-HCl to produce phenyloxamic acid chloride or other halides of aromatic oxamic acids

Solubilizing higher alcohols. H. TH. BÖHME AKT.-GES. AND HEINRICH BERTSCH. Fr. 635,977, June 14, 1927. See Brit. 272,919 (*C. A.* **22,** 1783).

Esters of vinyl alcohol. CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE GES. Brit. 285,095, Feb. 12, 1927. In passing a mixt. of C_2H_2 and a carboxylic acid such as HOAc over a heated catalyst (which may be formed with acetate or other salt of Zn or Cd and active C or silica), undesired secondary reactions are suppressed and the life of the catalyst is prolonged by passing the mixt. so quickly that more than half of it is unchanged. After fractionation, the residue is returned for retreatment. Details are given.

Separation of amines. BRITISH DYESTUFFS CORPORATION, LIMITED, REGINALD W. EVERATT AND ERNEST H RODD. Fr. 634,906, May 24, 1927. See Brit. 273,923 (*C. A.* **22,** 1982).

Esters of fatty acids. ERNST VECKER. Fr. 635,452, June 2, 1927. Esters of fatty acids are prepd. by treatment with an alc., *e. g.*, glycerol, in quantity less than the theoretical, and eliminating the excess of fatty acid by physical means such as washing.

Cyclic ketones. I. G. FARBENIND. A.-G. Fr. 636,065, June 16, 1927. Cyclic ketones are prepd. by condensing with an acid condensing agent, dicarboxylic anhydrides such as maleic anhydride with hydrocarbons or their derivs. having the peri position free. Diluent or fusion agents may be added. In examples, naphthalene and maleic anhydride, acenaphthene and maleic anhydride, acenaphthene and succinic anhydride, and naphthalene and succinic anhydride are condensed. Cf. *C. A.* **22,** 1981.

Cyclic ketones of more than nine-membered rings. M. NAEF & CIE. Fr. 32,615, Dec. 9, 1926. See U. S. 1,673,093 (*C. A.* **22,** 2755).

Aromatic hydroxyaldehydes. J. D. RIEDEL A.-G. Brit. 285,451, Feb. 17, 1927. Propenylhydroxybenzenes are oxidized with an excess of $PhNO_2$ in the presence of excess alkali hydroxide. $PhNH_2$ also may be present in the reaction mixt. Isoeugenol yields vanillin; 1-hydroxy-2-ethoxy-4-propenylbenzene yields the next higher homolog of vanillin and isochavibetol yields isovanillin. Compds. such as 2-methoxymethyl ether of 1,2-dihydroxy-4-propenylbenzene yield corresponding aldehydes.

Obtaining volatile alkaloids. GEORG W. F. F. KNOTH. U. S. 1,686,866, Oct. 9. In order to obtain alkaloids which are volatile with water vapor, finely divided plant material contg. the alkaloid is formed into a thin liquid pulp with water and milk of lime or other suitable aq. alk. liquid, and this pulp is introduced at the top of a column app. and treated with a countercurrent of steam.

Mercaptans. HERMANN STAUDINGER AND THADEUS REICHSTEIN (International Nahrungs-Genussmittel A.-G.). Can. 283,765, Oct. 2, 1928. Furylmethyl mercaptan is produced by converting furaldehyde into bis(furylmethyl) disulfide by treating it with NH_4HS, and subjecting the bis(furylmethyl) disulfide without isolating it to the action of a reducing agent.

Amino metal mercapto compounds. WALTER SCHOELLER, ADOLF FELDT, MAX GEHRKE and ERICH BORGWARDT (to Chemische Fabrik auf Actien vorm. E. Schering). U. S. 1,685,341, Sept. 25. Compds. such as the Na salt of 4-acetylamino-2-argentomercaptobenzene-1-carboxylic acid and 4-*m*-aminobenzoylamino-2-auromercaptobenzene-1-carboxylic acid may be used (suitably in the form of their Na salts) in combating spirochaetae and may be formed by reacting on amino metal mercaptobenzenecarboxylic acid compds. with an acylizing agent. The products may be used by subcutaneous or intravenous injection. U. S. 1,685,342 relates to corresponding compds. contg the sulfonic group instead of the carboxylic group and describes the production of the

Na salt of 4-acetylamino-2-argentomercaptobenzene-1-sulfonic acid and the corresponding 2-auromercapto compd.

Guanidine derivatives. HELMUTH MEIS and EDUARD TSCHUNKUR (to I. G. Farbenind. A.-G.). Can. 283,751, Oct. 2, 1928. Disubstituted guanidines are manufd. by treating cyanogen halide with a primary org. base (amine), a deriv. or substitution product thereof, in the presence of a salt of an org. base (an aniline salt, a toluidine salt or the like).

Methylol ureas. G. WALTER. Brit. 284,272, Nov. 28, 1925. Methylol compds. of urea, thiourea and their derivs. are obtained by reaction on urea, thiourea or derivs. with CH_2O or its polymer in an org. solvent such as alc. and preferably in the presence also of a base such as NaOH. Cf. *C. A.* **21,** 3626.

Oxalates. GUY H. BUCHANAN and GEORGE BARSKY (to American Cyanamid Co.). U. S. 1,687,480, Oct. 9. Ca oxalate is treated with an alkali metal carbonate such as Na_2CO_3 in the presence of water at a temp. above 40° (with an excess of 15–35% of the carbonate) to form a soln. of alkali metal oxalate.

Tetrazoles. A. BOEHRINGER (trading as C. H. Boehringer Sohn). Brit. 285,080, Feb. 11, 1927. Tetrazoles are made by treating esters of oximes, suitably the sulfonic esters, or their so-called Beckmann transformation products, with azides or free hydrazoic acid, or by treating the esters, in the presence of hydrazoic acid, with substances such as thionyl chloride and $POCl_3$ or PCl_5 which effect the transformation. Examples are given of the production of 1-benzyl-5-amino-1,2,3,4-tetrazole by esterifying phenylacetamid-oxime with benzenesulfonic acid and heating the product with alc. Na azide, and of 1-phenyl-5-amino-1,2,3,4-tetrazole by esterifying benzamide oxime with benzenesulfonic chloride in NaOH soln. and then boiling with alc. Na azide. Cf. *C. A.* **22,** 3170.

Water-soluble organic stibinous compounds. MORRIS S. KHARASCH (to Eli Lilly & Co.). U. S. 1,684,920, Sept. 18. Compds. are made which have the Sb atom bonded by at least one bond to a C atom of an org. radical (preferably phenyl) and have the Sb bonded by its remaining bond or bonds to a S atom or atoms, each of which S atoms is bonded to a C atom of an org. radical contg. an acid group which has a free valence bond capable of being attached to H or a metal. *p*-Hydroxyphenylstibinous iodide, $HOC_6H_4SbI_2$ (m. 112–115° and made by a method described in detail) when combined with 2 mol proportions of thiosalicylic acid (I) in alc. soln. yields HI and *p*-hydroxyphenylstibinousthiosalicylic acid, insol. in water and ether and somewhat sol. in acetone and abs. alc., having an indefinite m. p. and decompg. when heated and forming salts with Na, K, NH_4, Ca and like metals. *p*-$HOC_6H_4SbCl_2$ (m. 128°), by reaction with 2 mol. proportions of *p*-mercaptobenzenesulfonic acid (II) similarly yields *p*-hydroxyphenylstibinous-*p*-thiobenzenesulfonic acid (a white substance which does not melt or decomp. below 300°), the Na salt of which is also described. *p*-HOC_6H_4-$SbCl_2$, by similar reaction with thioglycolic acid, yields *p*-hydroxyphenylstibinous-thioglycolic acid, which decomps. in melting and forms salts, the Na salt being particularly mentioned. *p*-Acetylaminophenylstibinous chloride-HCl monohydrate and I form *p*-acetylaminophenylstibinousthiosalicylic acid, m. about 200°, and which forms salts such as those of Na, K, NH_4 and Ca. *p*-Acetylaminophenylstibinous chloride-HCl monohydrate and β-mercaptopropionic acid, heated to 50–60° in alc., yield *p*-acetylaminophenylstibinousthiopropionic acid, m. 105–7°, and forming salts with Na and other metals. $C_6H_5SbI_2$ with II yields phenylstibinousthiobenzenesulfonic acid which does not melt or darken below 300°. *p*-Acetylaminophenylstibinous chloride-HCl monohydrate and II produce *p*-acetylaminophenylstibinousthiobenzenesulfonic acid, the Na salt of which is a trypanocide. *p*-Aminophenylstibinous chloride (manuf. of which is described) with II forms the hydrochloride of *p*-aminophenylstibinous-thiobenzenesulfonic acid which forms salts with alkali and alk. earth metals. *p*-Aminophenylstibinous chloride-HCl with I yields *p*-aminophenylstibinousthiosalicylic acid-HCl which begins to decomp. about 110° and forms Na and other salts. In this reaction the chloride or oxide may be also used as starting material instead of the hydrochloride. *m*-Aminophenylstibinous chloride with I yields a product similar to that from the *p*- compd. *p*-Acetylaminophenylstibinous chloride-HCl monohydrate with cysteine-HCl yield a white product which is very hygroscopic. Phenylstibinous iodide, chloride or oxide and I produce phenylstibinousthiosalicylic acid, m. 186°. In general products as described are therapeutically active and have relatively low toxicity.

Oxidation of aldoses. CHEMISCHE FABRIK VORM. SANDOZ. Fr. 635,603, June 7, 1927. Aldoses are transformed into the corresponding monocarboxylic acids by oxidizing the sugar in alk. soln. with a hypochlorite in the presence of small quantities of Br or I compds. Examples are given of the oxidation of glucose, galactose and lactose.

Decolorizing tartaric acid solutions. URBAIN CORPORATION. Fr. 32,633, Apr. 9,

1926. Addn. to 622,649. The process of the parent patent is extended to the treatment of all mother liquids with active C, as a suspension or in the form of an absorption column with or without alkali alginate or colloids.

Perylene. CHARLES H. MARSCHALK. U. S. 1,684,738, Sept. 18. A P ester contg. the β-dinaphthol radical such as the chlorophosphoric ester is heated to effect distn. in the presence of Zn and $ZnCl_2$. Cf. *C. A.* **21,** 3204.

Perylene and its derivatives. I. G. FARBENIND. A.-G. Fr. 635,599, June 7, 1927. See Brit. 272,528 (*C. A.* **22,** 1859).

Acetaldehyde. HUGH S. REID and WALDO C. HOVEY (to Canadian Electro Products Co.). U. S. 1,687,228, Oct. 9. See Can. 270,333 (*C. A.* **21,** 3368).

Acetic acid. I. G. FARBENIND. A.-G. Brit. 284,588, Jan. 29, 1927. EtOAc is employed as a solvent in concg. HOAc solns. by distn. Water and EtOAc distil off at 69–70° and the condensate seps. into 2 layers and the ester is returned to the still. When the temp. rises to 77°, concd. HOAc remains in the still.

Acetic anhydride. WILLIAM P. SKERTCHLY (to Henry Dreyfus). Can 283,817, Oct. 2, 1928. Ac_2O contg. S and S compds. is purified by treatment with NaOAc, or other alkali or earth alkali or other metallic acetate or two or more of such acetates and Cl, the Ac_2O being subsequently distd

Acetic anhydride. I. G. FARBENIND. A.-G. Brit. 285,090, Feb. 11, 1927. Water vapor is removed from a vapor mixt contg. Ac_2O and the latter is simultaneously condensed by adding an inert low-boiling solvent such as C_6H_6, toluene, $CHCl_3$, trichloroethylene or ethylene chloride (or a mixt. of such compds.) to carry away the water vapor, with or without the addn. of a higher-boiling solvent such as *o*-dichlorobenzene, quinoline or quinaldine or a mixt. of these to reduce the vapor tension of the anhydride. A sepg. column and dephlegmator may be used.

Acetic anhydride. CONSORTIUM FÜR ELEKTROCHEM. INDUSTRIE G.m.b.H. Fr. 635,248, May 31, 1927. See Brit. 272,951 (*C. A.* **22,** 1783).

Purifying benzoic acid and its derivatives. ALPHONS O. JAEGER (to Selden Co.). U. S. 1,685,634, Sept 25. In order to sep. benzoic acids from the corresponding phthalic acids, an aq. dispersion of the acids is subjected to continuous leaching with a current of org. solvents for benzoic acid, such as gasoline or C_6H_6, the solvent is sepd. from the water and the benzoic acids and phthalic acids are recovered from the solvent and from the water, resp.

Separating benzoic acids from phthalic acids. ALPHONS O. JAEGER (to Selden Co.). U. S. 1,686,913, Oct. 9. A mixt. contg. benzoic and phthalic acids, such as that obtained by catalytic oxidation of $C_{10}H_8$, etc , is subjected to the action of steam at a temp. not substantially above that at which the phthalic acids are substantially transformed into anhydrides (suitably about 150–175°), and the steam and benzoic acids are permitted to leave the mixt. and the benzoic acids are sepd. from these vapors by fractional condensation.

Maleic acid and maleic anhydride. A. BOEHRINGER (trading as C. H. Boehringer Sohn). Brit. 285,426, Feb. 16, 1927. Maleic acid and anhydride are produced by catalytic oxidation with oxidizing gases of compds. of the furan series such as furan, furfuryl alc., furfural, methylfurfural, hydroxymethylfurfural and pyromucic acid or their mixts. (which may be crude products) or mixts. of furan compds. with aromatic hydrocarbons or substances capable of forming compds. of the furan series such as dehydromucic acid. V or Mo oxides or other usual oxidizing catalysts may be used.

Phthalic anhydride. CHESTER E. ANDREWS (to Selden Co.). U. S. 1,685,624, Sept. 25. A mixt. contg. both phthalic anhydride and $C_{10}H_8$ such as the mixt. resulting from partial oxidation of $C_{10}H_8$ is vaporized into a flowing current of air or purified flue gas or other inert gas while heated to a temp. of about 200° and the resulting gas and vapor mixt. is cooled in successive stages (in an app. which is described, having a series of collection chambers), separately to crystallize the vaporous substances. Other substances may be similarly purified.

Phthalic anhydride. A. O. JAEGER (to Selden Co.). Brit. 285,017, Feb. 8, 1927. Phthalic anhydride obtained by catalytic oxidation of $C_{10}H_8$ vapor is purified by subjecting it to conditions favoring condensation and polymerization of unsatd. components so that substances of much higher b. p. than phthalic anhydride are formed from the impurities and sepn. is then effected by distn. or sublimation. The condensation, etc., may be effected by heating at about the b. p. of phthalic anhydride for several hrs. or by heating at a lower temp. with MnO_2 and Cl. Numerous modifications and details of procedure are also given.

Sulfonic acids. G. S. PETROV. Brit. 284,859, Feb. 1, 1927. Sulfonic acids of high mol. wt. made by sulfonating hydrogenated anthracene, hydrocarbons of the ter-

pene series or turpentine with sulfo-aromatic fatty acids are purified by mixing their solns. in water or aq. alc. with hydrocellulose, wood powder, finely ground sawdust or other porous cellulose material. The mass may be dried at a moderate temp. and extd. with benzine, benzene and alc. used successively. Several examples are given.

Anilinedisulfonic acid. I. G. FARBENIND. A.-G. Brit. 285,488, Feb. 18, 1927. Aniline-2,5-disulfonic acid is made by sulfonating aniline-3-sulfonic acid with oleum until the monosulfonic acid has disappeared and subjecting the resulting mixt. of di- and trisulfonic acids to the action of dil. acids.

2,3-Aminonaphthoic acid. I. G. FARBENIND. A.-G. Brit. 284,998, Feb. 7, 1927. 2,3-Hydroxynaphthoic acid is fused with $ZnCl_2.NH_3$ and NH_3 may be passed over the mass during the reaction. The product is extd. with hot HCl after washing out the $ZnCl_2$ with cold dil. HCl, and the 2,3-aminonaphthoic acid is purified by dissolving with an alkali and pptg. with an acid.

Menthol. RHEINISCHE KAMPFER-FABRIK GES. Brit. 285,394, Feb. 15, 1927. Liquid menthol mixts. are obtained in the hydrogenation of thymol, menthone and isomenthone comprising inactive neomenthol and some inactive menthol. By combined use of a freezing-out and fractional distn. these products are sepd. and the inactive menthol is purified by conversion into esters or ester acids followed by crystn and sapon. Details are given. Cf. *C. A.* **22,** 2573.

Menthol. RHEINISCHE KAMPFER-FABRIK GES. Brit. 285,403, Feb 15, 1927. *dl*-Neomenthol and *dl*-neoisomenthol are transformed, separately or together, into *dl* menthol by catalytic hydrogenation, by heating with mentholates of alkali or alk. earth metals, Mg or Al, or by oxidation with chromic acid or treatment with dehydrogenation catalysts followed by hydrogenation of the resulting *dl*-menthone or *dl*-isomenthone. Various details are given.

Diethylene glycol dinitrate. WM. H. RINKENBACH (one-half to Walter O. Snelling). U. S. 1,686,344, Oct. 2. This compound is made by reaction of diethylene glycol with a mixt. of HNO_3 25%, H_2SO_4 67% and H_2O 8%. It is a liquid of lower viscosity than nitroglycerin and is suitable for use in *explosives*.

Tetranitrodianthrone. BERTHOLD STEIN (to Grasselli Dyestuff Corp.). U. S 1,686,992, Oct. 9. Tetranitrodianthrone, in which the nitro groups are attached in a β-position is made by treating dianthrone with HNO_3 and H_2SO_4 at 0–5°. It forms colorless crystals, difficultly sol. in concd. H_2SO_4 and in most org solvents, and by weak alk agents such as pyridine it is transformed into the isomeric tetranitrodianthranol It may be used for making *dyes* and other compds.

Hexahydroaniline. WILHELM LOMMEL and THEODOR GOOST (to I G. Farbenind. A.-G.). Can. 283,752, Oct 2, 1928. Aniline is heated to 250–300° in the presence of Co as a catalyst and with a H pressure of about 100 atm.

1-Phenyl-2-methylaminopropanol. W. MERCK, K. MERCK, L. MERCK, W. MERCK and F. MERCK (trading as the Firm of E. Merck) Brit. 284,644, Feb 2, 1927. This compd. is prepd. by reaction of methylamine on 1-phenyl-1-keto-2-bromopropane in aq. soln., with or without addn. of benzene or other suitable org. solvent which is not miscible with water below 50°, pptg. the resulting 1-phenyl-1-keto-2-methylaminopropane with gaseous HCl and reducing

1-Phenyl-3,4-trimethylenepyrazolone. CHARLES MANNICH. U. S. 1,685,407, Sept. 25. This compd. forms slightly colored crystals, m 183–4°, is insol. in water but sol. in EtOH, MeOH and caustic alkalies It may be made by treating the reaction product of esters of ketopentamethylenecarbonic acids and phenylhydrazine with alk. condensing agents and is suitable for making *dyes* and *medicinal compds*. Cf. *C. A.* **21,** 3371.

***N*-Hydroxyethyl derivatives of aminophenols.** GUSTAV REDDELIEN AND WERNER MUELLER (to I. G. Farbenind. A.-G.). Can. 283,750, Oct. 2, 1928. *p* Aminophenol is condensed with ethylene oxide in the presence of a catalyst

Vanillin. F. BOEDECKER. Brit. 285,156, Nov. 12, 1926. See Can. 275,947 (*C. A.* **22,** 1597).

Vanillin. F. BOEDECKER. Brit. 285,551, Nov. 16, 1926. See Can. 275,948 (*C. A.* **22,** 1597).

Vanillin and isovanillin. J. D. RIEDEL. Fr. 32,559, Nov. 19, 1926. Addn. to 624,227. Safrole or isosafrole is heated with an alc. alkali to obtain *m*- and *p*-propenylpyrocatechol monomethoxymethyl ethers which are sepd. by fractional crystn. of their Na salts. In an example safrole is heated with MeOH-KOH in an autoclave and the product transformed into the Na salts and the methoxyisoeugenol allowed to crystallize out. The methoxyisochavibetol salt is left in soln. and these derivs. are converted into vanillin and isovanillin in known manner.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Rate of liberation of tryptophan from proteins by enzymes. IDA KRAUS-ROGINS. Univ. of Chicago. *Proc. Soc. Exptl. Biol. Med.* **25,** 449–50(1928).—Casein, edestin, Witte peptone and squash seed globulin were subjected to trypsin hydrolysis and free tryptophan was detd. In 1 hr. $^3/_4$ of the total available tryptophan in casein was liberated, a little less than $^1/_2$ was liberated from edestin, and $^1/_6$ from squash seed globulin. Witte peptone had $^1/_3$ of the total tryptophan available before incubation with trypsin and in 1 hr. of incubation $^2/_3$ was available. Equil. was established in 24 hrs. for peptone, 72–96 hrs. for casein, and 120 hrs. for edestin and squash seed globulin. Pepsin and erepsin did not liberate tryptophan from these proteins, and trypsin is the only enzyme involved. The effects of Na and Cl ions on the pptn. of tryptophan by $HgSO_4$ were studied. C. V. B.

Demonstration of rapid pepsin-hydrochloric proteolysis in vitro. WM. H. WELKER. Univ. of Illinois. *Proc. Soc. Exptl. Biol. Med.* **25,** 450–1(1928).—The addn. of a small quantity of solid pepsin to fibrin jelly causes an almost immediate soln. of the fibrin at room temp. The sol. protein products are different from fibrinogen, and they are largely proteose. C. V. B.

Glass surfaces versus paraffin surfaces in blood-clotting phenomena. An hypothesis. ROSS A. GORTNER AND DAVID R. BRIGGS. Univ. of Minnesota. *Proc. Soc. Exptl. Biol. Med.* **25,** 820–1(1928).—Streaming potential measurements showed that a bare glass capillary had a negative electrokinetic potential of 30 millivolts, and if coated with paraffin it has a zero potential against water. The high potential would favor electrostatic adsorption of positively charged colloids at the interface of glass-blood serum, and there would be no such tendency for a paraffin-blood serum interface. It is suggested that the initial step in blood clotting involves a surface concn. of some positively charged constituent, the concn. being brought about by selective adsorption. C. V. B.

Formation of oxygen from carbon dioxide by protein-chlorophyll solutions. M. EISLER AND L. PORTHEIM. *Biochem. Z.* **192,** 132–6(1928).—The authors' original results (*C. A.* **17,** 2717) are maintained in reply to the criticisms of Dolk and van Veen (*C. A.* **21,** 3383). B. C. A.

Further investigations of the oxidative principle (oxone) of the blood and bone-marrow. ALFRED NEUMANN. *Verhandl. deut. Kongresses innere Medizin* **1927,** 370–2; *Chem. Zentr.* **1927,** II, 2686.—By means of HCl-EtOH a fatty substance was obtained from the eosinophilic granule of the blood corpuscles, which after HCl-EtOH extn. leaves a residue giving a benzidine reaction. From the red bone-marrow can be obtained by adsorption by kaolin and extn. with AcOH at various temps. several peroxidatively active fractions, of which one seems to contain a porphyrin-like substance. All the fractions contain Fe. C. C. DAVIS

Influence of the endocrine glands on the catalase of the blood. STEFANO CASTAGNA. Univ. Sassari. *Arch. farmacol. sper.* **45,** 209–14(1928).—White rats after castration showed a diminished catalase activity in the blood. This is attributed to diminished metabolism, especially with regard to oxidative processes and hence less occasion for the decompn. of peroxides. A. W. DOX

Cozymase. XV. HANS VON EULER AND KARL MYRBÄCK. Univ. Stockholm. *Z. physiol. Chem.* **177,** 237–47(1928); cf. *C. A.* **21,** 3910, and following abstract.—Concd. boiled ext. of yeast was dialyzed through collodion and partially purified by treatment with $Pb(OAc)_2$. The filtrate was further purified by pptn. with $Pb(OAc)_2$ and NaOH, the ppt. decompd. by H_2SO_4, the filtrate pptd. by $Hg(NO_3)_2$, the ppt. decompd. by H_2S, the filtrate treated with $AgNO_3$ and the ppt. discarded; the filtrate pptd. by careful addn. of NH_4OH and the ppt. decompd. by H_2S. The last filtrate was pptd. by phosphotungstic acid and 2% H_2SO_4, the ppt. suspended in dil. HCl and extd. with a mixt. of Et_2O and AmOH. Evapn. of the solvent and pptn. by EtOH or MeAc gave a highly active prepn. Picric acid then pptd. a cryst. substance, m. 209°, which was identified as the picrate of *adenylthiomethylpentose*. The filtrate from this, after removal of picric acid, still contains S, probably as the above thio deriv., but the cozymase activity is increased enormously. The most active prepns. gave a phloroglucinol reaction, the intensity of which varied with the cozymase activity.

Such prepns. have no m. p. and have not yet been obtained in cryst. form. At 110° some sublimation occurs, but the sublimate and residue are both inactive. The cozymase prepns. do not reduce alk. Cu soln. until after hydrolysis. The greater part (90%) consists of a substance which contains adenine (identified as the picrate) and a N-free residue of equiv. wt. 350. From the latter some furfural is obtained by acid distn. Mol. wt. of the cozymase prepn. was 486 by actual detn. and 480 by calcn. from the above constituents. Cozymase is thus a sort of nucleoside or nucleotide, or else comprises a very small proportion of the prepn. Assumption of a nucleoside structure is supported by the fact that liver and kidney maceration and a purified nucleosidase prepn. rapidly inactivate cozymase with liberation of reducing sugar, whereas other enzymes such as pepsin and esterase are without effect. Cozymase is remarkably stable to oxidizing agents such as $KMnO_4$ and Br-H_2O. A. W. Dox

New investigations on cozymase. Hans von Euler and Karl Myrbäck. *Chimie et industrie* **Special No.,** 819–20(April, 1928); cf. *C. A.* **21,** 3910, and preceding abstract.—In HNO_3 soln., $AgNO_3$ partially ppts. cozymase; complete pptn. can be obtained from neutral soln. by means of ammoniacal $AgNO_3$ and $Ba(OH)_2$, the resultant product having an activity of 10,000–20,000 units. In acid soln $HgSO_4$ does not ppt. cozymase; but complete pptn. may be obtained with $Hg(NO_3)_2$ if sufficient NaOH is added to make the soln. weakly acid or neutral. Hg is eliminated with H_2S and the activity of the product is similar to that obtained from $AgNO_3$. Phosphotungstic acid ppts. cozymase completely from HCl solns. On shaking the ppt. with 1:1 Et_2O-AmOH in presence of aq. HCl, the phosphotungstic acid is eliminated with practically no loss in activity (contrary to elimination with $Ba(OH)_2$), giving a product with an activity of 60,000–70,000 units. The phosphotungstic salt of cozymase is sol. in 50% Me_2CO, and the purity of the cozymase can be increased by a method of fractional soln. From solns which have been purified by Pb and Ag salts and by phosphotungstic acid, picric acid ppts. large quantities of inactive picrates; the cozymase can be pptd. (sometimes completely) with silicotungstic acid, and the cozymase obtained from this ppt has a variable activity, usually 20,000–30,000 but sometimes 50,000–77,000 units Cozymase gives the characteristic reactions of pentoses with phloroglucinol and HCl and with orcinol, to an extent almost to equal to the nucleoside adenosine; but the latter does not accelerate fermentation by zymase. Purified cozymase does not give the reactions of proteins. Its mol. wt., detd. by the diffusion method, is 485 ± 10. It shows striking similarity in chem. properties with vitamin B and with the H_2O sol. growth factor; but has a lower thermostability than the former A Papineau-Couture

Enzyme chemistry of the processes of acid formation by Aspergillus niger. II. K. Bernhauer and H. Wolf. German Univ. Prague. *Z physiol Chem* **177,** 270–9 (1928); cf. *C. A.* **22,** 3187 —By cultivating the fungus on a substrate contg acid of definite p_H (0.04–0.02 N H_3PO_4, 0.02 N HCl, p_H = 2.8–3.0) its ability to form citric acid can be increased considerably. The more vigorous mycelium development resulting from the use of H_3PO_4 does not explain this phenomenon, since HCl has the same influence on acid production without increasing the fungus growth. The acid appears to have a direct influence on the formation of the enzyme complex. Various strains of *A. niger* differ in respect to their ability to form acid. The triturated mycelium can under suitable conditions produce acid from glucose. The formation of glucuronic and oxalic acids indicates that these processes are of enzymic nature. Citric acid formation under such conditions could not be demonstrated. With further development the method should be useful in furnishing an insight into the processes of acid formation by fungi. A. W. Dox

The linkage relationships of the nucleic acid in yeast. N. Ishiyama. Univ. Berlin. *Z. physiol. Chem.* **177,** 295–7(1928).—The nucleic acid in animal cells (fish sperm, thymus gland, etc.) is accompanied by a basic protein such as protamine or histone. Thus far no basic protein has been found associated with the nucleic acid of plants. By treatment of dried yeast with $CuCl_2$ and Na picrate an attempt was made to sep. a basic protein but without success. Evidently no protamine-like substance is present in yeast. The linkage relationships of yeast nucleic acid must therefore be essentially different from those of thymonucleic acid, but the nature of this linkage remains undetd. A. W. Dox

The peroxidase nature of "active" iron. H. Ucko. Charite, Berlin. *Klin. Wochschr.* **7,** 1515–7(1928).—Baudisch and Welo (cf. *C. A.* **19,** 3198) have claimed that Fe compds. must be classified as active and inactive depending upon their ability to transfer O from peroxides to easily oxidizable substances The methods used in classifying these forms of Fe are not very reliable, however, for Fe forms colored compds. with benzidine, for example, that are indistinguishable from the blue color that is

usually interpreted as a test for peroxidase action. A table is given in which the effect of Fe compds. of diverse types on various solns. of benzidine, with and without H_2O_2, of pyrogallic acid, and of KI, with H_2O_2, is given. The general conclusion is opposed to a classification of Fe as active or inactive. MILTON HANKE

The resorption of carbon dioxide through the skin. STEPHEN HEDIGER. *Klin. Wochschr.* 7, 1553-7(1928).—The diffusion of CO_2 into and out of the skin can be studied by attaching a glass vessel contg. a soln. of CO_2 to some flat area of the body and analyzing the liquid for CO_2 from time to time. An equil. is established when the CO_2 pressure is approx 40-50 mm. Hg. The loss of CO_2 from liquids of high concn. or the acquisition of CO_2 by distd. water placed in contact with the skin follows the laws of diffusion. As much as 200 cc. CO_2 per min. can be absorbed by a person bathing in a natural water that contains CO_2. MILTON HANKE

Thelykinin in bile. M. A. GSELL-BUSSE. *Klin. Wochschr.* 7, 1606(1928).—A brief report. The detailed report is to appear in *Arch. ges. Physiol.* M. H.

Structure and enzyme reactions. IV. The system: glycogen-amylase-lipoids. RICHARD TRUSZKOWSKI. Biochem. Lab., Warsaw Univ. *Biochem. J.* 22, 767-72 (1928); cf. *C. A.* 22, 1985.—Amylase is adsorbed upon lipoids to about 67% of the quantity in soln. The enzyme can be completely eluted by narcotics, only partially by glycogen and altogether resists the action of water. The addn. of lipoids to the system glycogen-amylase retards hydrolysis. Amylase, it seems, when adsorbed by lipoids is inactivated, and the activity can be restored by elution. B. H.

Studies of lipin-protein complexes. I. Lecithin-caseinogen complexes. THOMAS R. PARSONS McGill Univ. Clinic, Montreal. *Biochem. J.* 22, 800-10(1928).—The percentage of lecithin in the ppts. obtained by the addn. of a mixt. of lecithin and caseinogen to buffer solns. of graded acidity increases with increasing H-ion concn. of the medium. When mixts. of caseinogen and increasing quantities of lecithin are added to the same buffer soln. the increase in the percentage of lipin in the several ppts. becomes more and more gradual. BENJAMIN HARROW

Structure and enzyme reactions. Parts V and VI. The system: glucose-enzyme and ester catalyst. STANISLAUS JOHN PRZYLECKI, WENCESLAUS GIEDROYĆ AND ERNEST A. SYM. Biochem. Lab., Warsaw Univ. *Biochem. J.* 22, 811-25(1928); cf. *C. A.* 22, 1985.—In the system enzyme + concd. glucose soln. ⇄ enzyme + hexobiose + H_2O, the reaction attains a definite equil. point, the value of which, in systems without charcoal, depends upon the initial concn. of glucose. This system can be used for the demonstration of the postulate that structure may influence reaction by changing the value of K and so augmenting synthesis, since the hexabiose formed is considerably more adsorbed than glucose, in solns. contg. over 20% of the latter and 1·2% of maltose. The reaction, acid + alc. ⇄ ester + water, proceeds under the catalytic influence of HCl in a medium contg. excess of alc. The addn. to this system of prepns of charcoal, which largely adsorb the org. acid, but not the ester, brings about the acceleration of hydrolysis. BENJAMIN HARROW

Phosphatases of mammalian tissues. HERBERT D. KAY. London Hospital. *Biochem. J.* 22, 855-66(1928).—The phosphatases of mammalian tissue have an optimum p_H between 8.8 and 9.3. Probably the same enzyme is responsible for the hydrolysis of glycerophosphate, of hexosediphosphate and of nucleotide. In the presence of the alc. concerned, inorg. phosphate can be esterified, using phosphatases as catalysts. In this way glycerophosphoric acid has been synthesized from glycerol. BENJAMIN HARROW

Hemoglobin as catalyzer. W. HEUBNER. *Naturwissenschaften* 16, 515(1928).—Referring to Warburg's (*C. A.* 22, 3672) recent note, it is pointed out that hemoglobin can under special conditions (high concn.) act as a catalyzer. A hydroquinone soln. can be made to absorb O by addn. of $^1/_{200}$ equiv. hemoglobin, likewise hydrazobenzene, phenylhydroxylamine and chlorate (cf. H. and Meier, *C. A.* 18, 1306). B. J. C. VAN DER HOEVEN

Clinical contribution to the action of ultra-violet rays in rickets and spasmophilia with special reference to blood phosphorus and calcium. GIUSEPPE VITETTI. *Pediatria Rivista* 36, 925-32(1928).—In a group of 18 children 9 months to 2.5 yrs. old an ultra-violet irradiation of 4 min. caused an increase of inorg. P in rickets and of Ca in spasmophilia. MARY JACOBSEN

Effect of arsenic compounds on animal enzymes. A. FIORI. *Rass. clin. terap. sci. affini* 27, 172-6(1928).—The inhibiting effect of As on amylase is confirmed. It was especially pronounced with glycerol exts. of glands. Na_3AsO_4 is more effective than Na_3AsO_3 or Me_2AsO_2Na. MARY JACOBSEN

An outline of the use of ultra-violet radiation in dermatology. W. Kerr Russel. *Am. Med.* **34,** 390–2(1928). Frances Krasnow

Hematogenic carbohydrate decomposition. Artur Abraham and S. Friedberg. Krankenhaus der judischen Gemeinde zu Berlin. *Arch. Verdauungs-Krankh.* **42,** 513–9(1928).—Glycogen and starch plus defibrinated blood produce lactic acid within 8 hrs. at 37°. Glycogen yields more acid than starch. Frances Krasnow

Influence of salts on the isoelectric behavior of proteins. Kinsuke Kondo and Tsunetomo Hayashi. *Bull. Chem. Soc. (Japan)* **3,** 146–51(1928); cf. *C. A.* **21,** 2284.—Curves are given illustrating the change of the isoelec. reaction of solns. of rice glutelin, and of the change of precipitability of the isoelec. rice glutelin upon adding to the solns. the chlorides of Rb, K, Na, Li, Ba, Ca, Mg, Co, Ni, Cu, Al and Fe. These curves indicate that both the isoelec. reaction as well as the isoelec. soly. of the protein vary according to the nature of the cation added, as well as according to its valence. "The ppt. may be due to the formation of a complex combining the protein and one component of the salt." No exptl. data are presented. W. D. Langley

Physiological effects of Röntgen radiation upon normal body tissues. Stafford L. Warren. Univ. Rochester. *Physiol. Rev.* **8,** 92–129(1928).—General review with extensive bibliography. E. R. Long

The anaerobic oxidases. H. S. Raper. Univ. Manchester. *Physiol. Rev.* **8,** 245–82(1928).—General review with extensive bibliography. E. R. Long

The precipitation of blood calcium by lead. Fritz Bischoff and L. C. Maxwell. Potter Metabolic Clinic and Santa Barbara Cottage Hosp., Cal. *J. Biol. Chem.* **79,** 5–17(1928).—"$Pb(AcO)_2$ added to serum with or without CO_2 tension ppts. a mol. equiv. of ultrafilterable Ca and an amt. of inorg. P required for the formation of $Pb_3(PO_4)_2$ and $Ca_3(PO_4)_2$. Since the amt. of Ca thrown out is independent of the p_H (6.9 to 8.3) and of the concn. of PO_4, CO_3, and Ca ions, the reaction is not immediately concerned with the soly. product of $CaCO_3$ or $Ca_3(PO_4)_2$. The reaction is a sp. Pb effect." A. P. Lothrop

The mechanism of enzyme action. II. Further evidence confirming the observations that ethylene increases the permeability of cells and acts as a protector. F. F. Nord and Kurt W. Franke. Univ. of Minn. *J. Biol. Chem.* **79,** 27–51(1928); cf. *C. A.* **22,** 1368.—By bubbling C_2H_4 through freshly prepd. yeast juice zymase solns. were obtained which not only maintained full activity for 65 days but showed an increased activity. The zymase was protected from the destructive action of protease in the juice. With living yeast cells the permeability of the treated yeast was greatly increased and the surface protected from the action of the products of fermentation. The effect on the permeability of cells in tissues was demonstrated by a marked increase in O_2 evolution by catalase in tobacco leaves treated with C_2H_4. The capacity of pyruvic acid to inactivate yeast could also be decreased by C_2H_4 treatment even during relatively long contact of the yeast with the acid. C_2H_4, therefore, is capable of being charged as a protector on sensitive biol. surfaces and due to adsorption it is also able to increase the permeability of cells. It is unlikely that the association between enzymes and substrate belongs in the group of true mol. combinations; it is more likely that the reactions are governed by purely physical forces. A. P. Lothrop

The electrometric titration of hemin and hematin. James B. Conant, Gordon A. Alles and C. O. Tongberg. Cal Inst. of Tech. and Harvard Univ. *J. Biol. Chem.* **79,** 89–93(1928), cf. *C. A.* **22,** 1986.—Satisfactory electrochem. titration curves can be obtained with alk. hemin and hematin solns. if $TiCl_3$ is used as the reducing agent. The results are very definite and show that the change involves only 1 equivalent. The expts. confirm the recent results obtained using entirely different methods by Haurowitz (*C. A.* **21,** 1661) and Hill (*C. A.* **21,** 3064), which show that the reduction of hematin, like that of methemoglobin, is the change from a ferric to a ferrous compd. A. P. Lothrop

Studies on metal proteins. VII. The variations in certain physico-chemical properties of egg albumin treated with powdered cobalt. G. B. Bonino and A. Carello. *Arch. sci. biol.* (Italy) **11,** 212–6(1928); cf. *C. A.* **22,** 3177.—In previous expts. the effect of Co on gelatin was investigated and evidence brought forth showing that certain facts could be deduced theoretically by considering gelatin as a "colloidal ampholyte." In this expt. the action of Co on egg albumin was studied in order to compare its behavior with that of gelatin as to (*a*) elec. cond. and (*b*) variation in H-ion concn. (*a*) Egg albumin was dild. with 3 times its vol. of distd. H_2O. The globulins were filtered off and the filtrate contg. the albumin was used. Part of the filtrate was brought into contact with powd. Co and its elec. cond. measured. At 25° the elec. cond. for egg albumin soln. before fixation with Co was (K) 0.00368, after

fixation with Co 0.00372. Since the difference in K was too small to draw any deductions, the cond. was decreased by dialyzing out the electrolytes. The K of albumin soln. before dialysis was 3.23×10^{-3}, after dialysis 0.052×10^{-3}. The cond. of albumin soln. after fixation with Co powder and then dialyzing was 0.1180×10^{-3}. Thus there was a distinct increase in elec. cond. due to the fixation of Co. (*b*) Albumin solns. were dialyzed against various concns. of HCl ($N/512$, $N/1024$, $N/2048$) and distd. H_2O. The p_H of the solns. at equil. with HCl was 5.50, 6.20, 6.50 and 6.66, resp. Albumin solns. were brought in contact with Co powder and treated similarly. The p_H at equil. was 6.56, 6.88 7.19, and 7.29, resp. There was a definite increase in p_H, which proves, therefore, that in the case of egg albumin the same general theoretical deductions can be drawn as with gelatin. **VIII. The activity of cobalt ions in cobalt-albumins.** *Ibid* 217–23.—The fixation of Co by albumin was studied exptly. on the basis of Donnan's membrane equil. Samples of albumin at various p_H were placed in collodion sacs in equil. with dil. HCl of different concns. When equil. was reached, the sacs were suspended in beakers filled with distd. H_2O at the bottom of which was placed powd. Co reduced with H. The samples of albumin were then placed in equil. with the external liquid, the p_H was detd. and also the concn. of Co in the external and internal liquid of the membrane. From Donnan's membrane equil. the following relation should hold: $A_{2H}/A_{1H} = \sqrt{A_{2Co}/A_{1Co}}$. A_{1H} and A_{2H} were detd. by the usual methods. The concns. of Co were measured by chemical-analytical methods. Tables are given showing the p_H of the metal-albumin, A_{1H}/A_{2H}, A_{1Co}/A_{2Co}, and $\sqrt{A_{1Co}/A_{2Co}}$, also p_H of metal-albumin and $\sqrt{f_1 Co}$. At low p_H, the coeff. of activity for Co^{++} approached unity. With increasing p_H, the coeff. of activity of Co^{++} diminished rapidly in Co-albumin; increasing the p_H had a tendency to bring about intermolecular reactions which masked the osmotic and electrochem. effects. There is thus a relation between H-ion concn. of an albumin soln. and the action which the albumin exerts on the activity of the Co^{++} ions. PETER MASUCCI

The surface tension of protein solutions at various hydrogen ion concentrations, before and after jellying. G. PUPILLI. *Arch. sci. biol.* (Italy) **12,** 373–92(1928).—The aim of these expts. was to show whether the low temps. causing albumin or gelatin to jelly would produce const changes in the surface tension of these protein solns. The solns. tested covered a range of p_H 2.0 to 10.0. Serum albumin solns. were dialyzed against distd H_2O for 30–40 days; they were then filtered. The albumin content was detd. by the refractometer. Gelatin solns. were prepd. according to the method of Dhéré and Gorgolewski; the p_H was detd. electrometrically the surface tension was measured by the Traube stalagmometer. Low temps. (—12–18°) were obtained with ice-salt mixts. Each soln. was tested for p_H and surface tension; it was then allowed to gel in the cooling mixt. for 30–45 min.; and then allowed to liquefy at room temp. The following day the surface tension was again detd. The results are reported in tables giving the p_H, the surface tension before and after jellying, and the concn. of the albumin or gelatin. Conclusion: The surface tension of serum albumin and gelatin which have been exposed to congealing temps. and then liquefied is increased when the solns. are at the isoelec. point (p_H 4.7), or at H-ion concns. close to it; it is unchanged between p_H 3.0–3.4 and p_H 8.0–9.0, and increases perceptibly beyond these zones. The phenomenon is attributed to the formation of mol. aggregates in the liquid, and to the various states of hydration of the protein particles. PETER MASUCCI

Partial hydrolysis of phosphoric acid from hexose-diphosphate by yeast. C. NEUBERG AND J. LEIBOWITZ. *Biochem. Z.* **191,** 450–5(1927).—Hydrolysis of hexose-diphosphate by the phosphatase of *Aspergillus oryzae* proceeds through the hexose-monophosphate stage. **The transformation of zymo-diphosphate into hexose-monophosphate ester by means of animal phosphatase.** *Ibid* 456–9(1927).—**Arsenate activation and the specificity of phosphatase.** *Ibid* 460–5(1927).—Evidence is adduced to show that there are at least 2 sp. phosphatases. Activated by arsenate, the taka-phosphatase yields principally Neuberg's ester ($[\alpha]_D = +24°$) while the kidney phosphatase gives practically pure Robison ester ($[\alpha]_D = +27°$). Without the arsenate activation only a mixt. of partial hydrolysis is obtained, *i. e.*, both monophosphate esters. S. MORGULIS

Structure of hexose-phosphate ester and of methylglyoxal according to the spectrographic behavior. CARL NEUBERG AND SVEND AAGE SCHOU. *Biochem. Z.* **191,** 466–71(1927).—Absorption curves for hexose-diphosphate, Neuberg's and Robison's ester and methylglyoxal are given. S. MORGULIS

Comparative studies on the influence of mountain climates on the blood catalase. A. I. ALEKSEEV. *Biochem. Z.* **192,** 41–57(1928).—In the first 3–4 weeks of sojourning

in the mountains there is an increase in the no. of erythrocytes, viscosity and catalase content of the blood. The blood catalase shows an av. increase of 70% during a 6–7 weeks sojourn, while the red cells show an increase of 38%. Towards evening the catalase activity diminishes 10–20% which is attributed to the effect of an anticatalase.
S. MORGULIS

The condition of the serum calcium. A. NITSCHKE. *Biochem. Z.* **192,** 123–7(1928); cf. *C. A.* **21,** 425.—According to the Donnan equil. the equil. const. of a supersatd. $CaCO_3$ soln. at 37° is $Ca^{++} \times HCO_3^-/H^+ = K = 2570$. At p_H 7.35 and HCO_3 67.2 vol. % the ionization limit of Ca is attained at 14.5 mg. %. For supersatd. $Ca_3(PO_4)_2$ at 37° the equil. const. is $Ca^{++} \times HPO_4^- = K = 67 \times 10^{-7}$. At p_H 7.35, 3.7 mg. % P and 10 mg. % Ca, 2.4 mg Ca is calcd. to be the mol. form as $CaHPO_4$, 2.0 mg. Ca in combination with serum protein and 5.6 mg Ca ionized. S. MORGULIS

Influence of different preparations of the quinine group on the enzymic functions of the organism. VIII. Digestion of edestin by pepsin in the presence of quinine-hydrochloride. I. A. SMORODINTZEV. *Biochem. Z.* **195,** 1–7(1928).—The diln. of the enzyme soln. with H_2O 1:8, or with 0.1% HCl, has no influence on the p_H of mixts. of pepsin and edestin. Quinine HCl of 0.2% concn. has no effect on the edestin digestion by pepsin. By increasing the quinine-HCl concn. to 0.5% there is sometimes observed a certain inhibition, which, however, can be counteracted by a slight increase in acidity. It is, therefore, concluded that the inhibition is due to a shifting of the reaction of the medium to the alk. side. Furthermore, by increasing the acidity of the mixt. to p_H 1.7 there is inhibition by quinine. S. MORGULIS

Molecules and ions in plasma. R. KELLER. *Biochem. Z.* **195,** 14–19(1928).—Physics in the last few years has furnished proof that strong electrolytes have very little mobility. Capillary chemistry has also shown that in the immediate vicinity of membranes, proteins or hydrophile colloids which generally are neg. charged the anions are entirely immobile while the cations are strongly inhibited. Exptl. studies of the permeability of animal and plant plasma membranes show that strong acids and bases do not pass into the living substance while strong electrolytes do so very slowly and to a very limited extent S. MORGULIS

Studies on the function of the cells of the recticulo-endothelial apparatus. A contribution to the permeability problem. N. OKUNEV. *Biochem Z.* **195,** 28–39 (1928).—Various colloids or watery suspensions which are taken up by the cells of the reticulo-endothelial system (trypan blue, carmin, cholesterol, India ink. colloidal Ag or Au, erythrocytes and bacteria) lower the surface tension of a H_2O-benzene, or H_2O-olive oil phase. It follows that these substances will tend to accumulate in the lipoid or lipoid solvent phase of a H_2O-lipoid system. S. MORGULIS

Enzymes and light. X. Diastase. 5. LUDWIG PINCUSSEN AND SUSUMI KUMANOMIDOH. *Biochem. Z* **195,** 79–86(1928).—Addn. of salts to salivary diastase or to malt diastase increases its instability to light rich in ultra-violet rays whereby K has the strongest and Ca the weakest effect In expts on the inactivation by heat the reverse situation is found in the ionic antagonism. **XI. Pepsin. 1.** LUDWIG PINCUSSEN AND KIKUSJI UEHARA *Ibid* 87–95(1928).—Pepsin is inactivated by exposure to light rich in ultra-violet rays, the loss of enzyme activity being related to the p_H of the mixt. It is greatest at p_H 1.15 and least at p_H 2.28 **XII. Lipase. 1.** LUDWIG PINCUSSEN AND SHIGERU HAYASHI *Ibid* 96–102(1928).—The serum lipase and esterase are much injured by exposure to light rich in ultra-violet rays. S. M.

Acyloin cleavage by means of enzymes from acetic acid bacteria. TORAO KITASATO. *Biochem. Z.* **195,** 118–27(1928). S. MORGULIS

Experimental studies on the influence of ultra-violet rays on the position of the "oxidation quotient" in urine. J. SPIRT. *Biochem. Z.* **195,** 142–8(1928).—The "oxidation quotient" is the ratio between amt. of O_2 required completely to oxidize the urinary N and the quantity of N excreted. This quotient is const in dogs (0.5–0.6) and the daily variations for the same dog are insignificant when the animals are kept on a diet sufficient to cover their N need. Radiation with ultra-violet rays causes a change in this quotient, increasing or diminishing according to the intensity of the radiation. Since the amt. of N excreted remains the same under these conditions the variations in the quotient are due to changes in the O_2 Radiation with the Hg lamp for 1/2 hr. at 80 cm. increases the quotient and hence inhibits the oxidative process. More intense radiation (1 hr. at 60 cm.) causes a lowering of the quotient, or an increased oxidation. In control dogs, kept in the dark, the quotient remained unaffected.
S. MORGULIS

Ultramicroscopic observations on the influence of inorganic ions on the dispersion of egg albumin and hemoglobin at different hydrogen-ion concentrations. VERA

SCHRÖDER. *Biochem. Z.* **195**, 210–9(1928).—The state of dispersion of egg albumin and hemoglobin solns. was detd. by counting the number of ultramicroscopic particles. The max. of flocculation which is observed at a certain H-ion concn. is altered through the addn. of salt. These were usually in a concn. of 0.05–0.10 *M*, *i. e.*, within the physiol. range. Anions shift the max. flocculation toward the acid side in the following order, $SO_4 < HPO_4 < Cl, Br, I < SCN$. Of the cations Ca and Mg have a definite effect, shifting the max. slightly to the alk. side. S. MORGULIS

Studies on iodine as a biogenous element. XV. Animal organs and products and their iodine content. K. SCHARRER AND J. SCHWAIBOLD. *Biochem. Z.* **195**, 228–32(1928).—The I_2 content of heart, liver, lung, kidney, spleen, fat and muscle of pigs varies from 5.5 to 40γ. Following long feeding with iodides the max. content is not very much increased, the greatest increase being in the liver, kidney and spleen (max. 66γ). The milk of cows and sheep fed on pastures close to or actually run over by the sea contains 300–800% more I_2 than from Swiss or Oberbayern cows. **XVI. The presence of iodine in feed and in artificial fertilizers.** *Ibid* 233–7.—Feed of sea origin (fish cake) was found to be especially rich in I_2. A high I_2 content was also found in fertilizers from crude phosphates. The superphosphates are particularly rich in I_2 in spite of their acid reaction. In Chile saltpeter no periodate was found and only traces of iodide, the bulk of the I being there in the form of iodates which are changed to iodides by reduction. S. MORGULIS

Effect of dilution on the p_H of buffer mixtures. I. M. KOLTHOFF. School of Chem., Univ of Minnesota. *Biochem. Z.* **195**, 239–47(1928).—Using the Debye-Hückel equation of the ionic-activity coeff and assuming an av. ionic diam. of 4×10^{-8} the influence of diln. on the p_H of common buffer mixts. can be calcd. For the calcn. of the citrate buffer p_H an av. diam. of 6.5×10^{-8} should be used. The diln. effect in the boric acid- borate buffer cannot be calcd. from this equation. S. MORGULIS

The regulation of the hydrogen-ion concentration in blood. IV. Studies on the chemical properties of quinone, hydroquinone and quinhydrone and their relation to the reduction-oxidation systems of the blood. SCHAU-KUANG LIU. III. Med. Klinik, Univ. Berlin. *Biochem. Z.* **195**, 248–73(1928).—Quinone, hydroquinone and quinhydrone produce irregular potential differences, and this is also true for the filtrates from their satd. solns. Satd. solns. of quinone have a smaller potential difference, those of hydroquinone a higher and of quinhydrone one intermediate between the two, from which it is concluded that quinone and hydroquinone are relatively more acid and alk., resp., while the quinhydrone is more neutral The rise in potential is a function of the reduction process of the system, $[C_6H_4O_2][H]^2/[C_6H_4(OH)_2] = Kr$, while the fall in potential is a function of the oxidation, $[C_6H_4(OH)_2][O]/[C_6H_4O_2] = Ko$. The potential is therefore directly proportional to the reduction and inversely proportional to the oxidation of the quinhydrone. The reduction of quinone is generally not measurable but the oxidation of hydroquinone is easily detd. Quinone is thus more sensitive to reducing agents and hydroquinone to oxidation agents The reduction and oxidation of the quinhydrone change not only the $[H^+]$ but also the number of charges resulting from these reactions. The e. m. f. $= RT/n \ln Ks + RT/n \ln [C_6H_4O_2][H^+]^2/[C_6H_4(OH)_2][O^{--}]$. Quinone, quinhydrone and hydroquinone can convert oxyhemoglobin and possibly also reduced hemoglobin to methemoglobin, the effect of the first two being very rapid. **V. Studies on the effect of separate salts, acids and bases, as well as temperature, on the changes in potential of quinone, hydroquinone and quinhydrone.** *Ibid* 274–300.—The velocity of soln. satn. and oxidation-reduction can be measured with the quinhydrone chain. The relation between the changes in potential and the rate of these reactions is worked out. The shift in the quinhydrone potential is not influenced by dil. salt solns. but is slowed down or even inhibited by satd. salt solns. The rate of soln. and satn. of quinhydrone quinone and hydroquinone is not doubled by a 10° rise in temp. The shift of the quinhydrone potential is marked in neutral soln. and is much greater in an alk than in acid medium. **VI. The thermodynamic action of different standard solutions on the quinhydrone chain.** *Ibid* 301–8.—The variation in potential of standard acetate solns. and quinhydrone electrode fluid is practically a linear function of the temp. variation, and is to a certain degree reversible. The sources of error of the quinhydrone chain due to temp. variations are discussed and it is shown that for p_H detns. the abs. temp. of both electrodes must be considered. **VII. The relation of buffering to the different chemical reactions of quinone, hydroquinone and quinhydrone, and the buffer regulation of the chemical reactions of blood and body fluids.** *Ibid* 309–35.—The potential is directly proportional to the diminution in H^+ and inversely proportional to its increase. **VIII. Effect of temperature on the shift of potential**

of serum, plasma, blood, blood cell suspension and hemoglobin with the quinhydrone electrode. *Ibid* 336–63.—The reaction velocity or the rate of potential fall of a 1:4 dild. serum is very nearly doubled through a 10° rise in temp. over the range of 10° to 40°, which holds also for similarly dild. blood. Low temp. is better suited to the detn. of the initial potential of serum, plasma, dild. blood or dild. hemoglobin solns. because the reaction velocity is thereby considerably slowed down. The chief defect of the quinhydrone chain for the detn. of blood p_H is in the reduction which takes place between quinhydrone and H^+ or hemoglobin, resulting often in readings which are too high. S. MORGULIS

Hormones and adsorption. H. ZONDEK AND H. W. BANSI. Krankenhaus Urban. *Biochem. Z.* **195**, 376–86(1928).—The adsorption of adrenaline on animal charcoal follows Freundlich's adsorption isotherm, and is greatly inhibited by narcotics. The inhibiting effect of the narcotics follows Richardson's law of the homologous series. Ca ions in small doses seem also to inhibit the hormone adsorption, but higher concns. of Ca ions and small doses of caffeine increase the adsorption of adrenaline by charcoal. S MORGULIS

The effect of lipoids on the diffusion of acids and alkalies in jellies. S. I. AFFONSKII. Biochem. Lab , Veterinary Inst., Kasan. *Biochem. Z.* **195**, 387–95(1928). Lecithin and cholesterol have an antagonistic effect on the diffusion of acids and alkalies in jellies, the former causing inhibition while the latter increases the diffusion The stimulating effect of the cholesterol is relatively weaker than the inhibiting action of the lecithin. With high concns. of cholesterol, however, the diffusion is likewise hindered. S. MORGULIS

The photocapillary reaction of plant phosphatides. I. Effect of salts on the reaction. FERD. HERČIK. Pflanzenphysiol. Inst., Brünn. *Biochem. Z.* **198**, 81–7 (1928); cf. *C. A.* **22**, 972 · Plant phosphatides which dialyze from pea seeds into salt solns. have a surface tension which rises or falls (+ or − photocapillary reaction) in a characteristic manner Cations promote this reaction while anions are practically without effect. **II. Photocapillary reaction in the presence of iron.** *Ibid* 88–97.—The photocapillary reaction of plant phosphatides dialyzed against different solns of $Fe(NO_3)_3$ was studied. The sign of the photocapillary reaction is detd. by the concn. of the soln , being pos in high and neg. in low concns. The greatest pos. reaction was observed in 0 01 *M* $Fe(NO_3)_3$ S. MORGULIS

The influence of fluorine on urease. MARTIN JACOBY. Krankenhaus Moabit, Berlin. *Biochem. Z.* **198**, 163–74(1928) ·F exerts the strongest effect on urease under the optimum conditions for the enzyme action. The F effect is obviously sp. for urease though there is no evidence of a stoichiometric relationship between the two. Soy bean prepns. obtained in Germany are also very good. Even the freshly prepd. Jack bean meal is activated by KCN Urease adsorbed on cholesterol can be dissolved by H_2O. By repeating the adsorption many times the adsorption is quantitatively increased. Diminishing the urease concn the adsorption by cholesterol can be at first reduced to a min. but this increases once more upon further diminution of the concn. S. MORGULIS

The non-protein serum colloids and their biological significance. KAZUTANE NIKAIDO. Krankenhaus Moabit, Berlin. *Biochem Z.* **198**, 175–94(1928) – Normal serum contains a substance which inhibits the agglutination of red blood cells by Jack bean. This inhibitory substance was found in rabbit, horse and human serum. This effect was strong only with purified agglutinin whereas against the agglutinating action of the crude bean prepn. it was slight The substance is pptd. from serum with 65% satn. with $(NH_4)_2SO_4$. It is insol. in lipoid solvents by which it is not injured. If the deproteinization of the serum is carried out in acid medium (KH_2PO_4) a very potent inhibitory soln. is obtained. The substance is not adsorbed by kaolin before deproteinization, but is completely removed from the protein-free filtrate. Results with cholesterol were more or less similar to those with kaolin. The substance is nondialyzable, and in electrodialysis it is partly adsorbed on the ppt. which is formed. Zsigmondy's ultra-filter which retains protein does not allow this substance to pass, whereas the Chamberland filter retains the inhibitory substance but allows the proteins to go through. The Jack bean agglutination is not inhibited either by glycogen or by Cu and Fe colloids. The substance is fairly resistant to boiling with strong acid or alkali and is resistant to putrefaction It possesses colloidal properties different from those of protein or lipoid. S. MORGULIS

The occurrence of free aldehyde groups in enzyme solutions. FERDINAND LEHR. Krankenhaus Moabit, Berlin. *Biochem. Z.* **198**, 204–5(1928).—In very active enzyme prepns. (urease, Takadiastase, pepsin, trypsin and catalase) the presence of free alde-

hyde groups could not be demonstrated by the aid of the very sensitive fuchsin-H_2SO_3 reagent. S. MORGULIS

Permeability. I. TRAUBE AND F. DANNENBERG. Techn. Hochschule, Berlin-Charlottenburg. *Biochem. Z.* **198,** 209-24(1928).—Exptl. evidence is offered to show that the theory of the presence of pores in membranes is untenable. S. MORGULIS

Effect of ultra-violet light on the dehydrogenases of pyruvic and glycerophosphoric acids. SVEN JUNGHAGEN. Univ. Lind. *Skand. Arch. Physiol.* **54,** 115-9(1928).—Dehydrogenases of pyruvic and glycerophosphoric acids like other enzymes are very rapidly destroyed by ultra-violet radiation. S. MORGULIS

Chemistry of bilirubin. I. Behavior of bilirubin in various solvents at variable hydrogen-ion concentrations. WILLIAM KERPPOLA AND ERKKI LEIKOLA. Univ. Helsingfors. *Skand. Arch. Physiol.* **54,** 120-6(1928).—The soly. of bilirubin in H_2O is closely associated with the H-ion concn., being greater the more alk. is the liquid; in acid soln. it dissolves with difficulty. Even in the special bilirubin solvents (Et_2O, $CHCl_3$, CS_2, C_6H_6, toluene) the soly. is greatly influenced by the H-ion concn. so that the color of the bilirubin soln. does not indicate the true total quantity unless the p_H of the soln. is also known. S. MORGULIS

The catalase system in animal tissues under different physiological and pathological conditions. II. Determination of catalase and anticatalase in the tissues of normal guinea pigs and white rats. E. D. GAGARINA AND V. D. YANKOVSKII. *Zhurnal exptl. biol. Med.* **9,** 50-7(1928); cf. *C. A.* **21,** 3636.—Aq. exts. from various organs of guinea pigs and white rats lose some of their catalase activity especially when exposed to 37°. This loss of activity is attributed to inactivation by an anticatalase, and this inactivation can be prevented by the addn. of alc. in concn. of 1:10,000. Organs with the greatest catalase content also show the largest anticatalase content. **III. Effect of chronic intoxication with morphine, arsenic and alcohol.** *Ibid* 59-67(1928).—Intoxication with morphine causes generally an increase in the catalase content of all tissues except the blood, where there is actually a decrease. The greatest rise was found in the liver and muscles. The anticatalase diminishes except in the liver and muscles. Chronic As poisoning causes a considerable increase in both catalase and anticatalase except in the blood, where there is a great diminution. Chronic alc. poisoning produces in white rats a fall in the catalase-anticatalase content of the liver and kidney and a rise in the blood and muscles. The catalase-anticatalase content is reduced particularly in those organs where the alc. causes much degenerative change. In guinea pigs alc. poisoning calls forth much less pronounced alterations of the catalase. S. MORGULIS

Nomenclature in biological chemistry. M. MACHEBOEUF. *Bull. soc. hyg. aliment.* **16,** 277-82(1928).—A general review of the decisions adopted at the 1923, 1924, 1925, 1926 and 1927 conferences of the International Union of Pure and Applied Chemistry. A. PAPINEAU-COUTURE

Jacques Loeb. W. J. V. OSTERHOUT. *J. Gen. Physiol.* **8,** No. 1, IX-LIX (1928).—Biography. C. H. R.

The influence of surface charge and of cytoplasmic viscosity on the phagocytosis of a particle. E. PONDER. New York Univ. *J. Gen. Physiol.* **11,** 757-77(1928).—This is a math. consideration of the phagocytosis of a particle. General conclusions: The greater the cytoplasmic viscosity, the less likely it is that particles will ultimately be ingested because high cytoplasmic viscosity tends to render the particle liable to removal by forces generated by movements of the surrounding fluid. The more rapid the rotation of the cell the less probable that the particle will be ingested. Ingestion is less likely to occur in a fluid in which the cells are moving with great velocities relative to their surroundings, allowance being made for any greater no. of collisions which may occur between cell and particle. These conclusions are considered only as approximations incapable of exptl. verification except in a general way. C. H. R.

The mechanism of the inflammatory process. III. Electrophoretic migration of inert particles and blood cells in gelatin sols and gels with reference to leucocyte emigration through the capillary wall. H. A. ABRAMSON. Kaiser Wilhelm Inst., Berlin-Dahlem. *J. Gen. Physiol.* **11,** 743-56(1928); cf. *C. A.* **22,** 439.—Particles of quartz and of certain other substances move cataphoretically in certain soft gels with the same velocity as in the sol. The speed is a function of the true viscosity of the sol or gel, and in soft gels is apparently not altered by the presence of gel structure. This is compatible with the fact that certain sols undergo gelation without change of true viscosity although the apparent viscosity changes markedly. Red blood cells in soft gelatin-serum gels migrate through the sol or gel with about twice the speed of leuco-

cytes and quartz particles. The latter two substances have the same velocity in this medium. The abs. viscosities are only slightly decreased by the presence of the gel. In stiffer gels, leucocytes, red blood cells and quartz particles move with equal velocity When the gels are mechanically softened, the red blood cells resume their independent velocity of migration Cataphoretic movement of particles in gelatin gels is different from that produced by magnetic force or the force of gravity. The mech. nature of obstruction to the cataphoretic migration of leucocytes and red blood cells in fibrin gels is described. Polymorphonuclear leucocyte emigration and migration are probably dependent upon p. ds in the capillary wall C. H. RICHARDSON

The mechanism of tonic immobility in vertebrates. H. HOAGLAND. Harvard Univ. *J. Gen. Physiol.* **11,** 715-41(1928).—Tonic immobility ("death feigning") in the lizard (*Anolis carolinensis*) was studied as a function of temp. The exptl. data which show the rate of change of the process when plotted as a function of temp. according to the Arrhenius equation are distributed in 2 straight line groups with temp. characteristics (μ) of 31,000 and 9000 cals., resp. The results are interpreted by assuming the release, through reflex simulation, of hormones, one effective between 5° and 35°, the other between 20 and 35°. They probably act as selective inhibitors of impulses from "higher cente[illegible] [illegible]mitting impulses from tonic centers to pass to the muscles. Other physiol. inf[illegible] [illegible] on this subject is given C. H. RICHARDSON

The influence of p_H upon th[illegible] [illegible]oncentration potentials across the skin of the frog. W. R. AMBERSON AND H. KLEIN[illegible] Univ [illegible] [illegible]rine Biol. Lab., Woods Hole, Mass. *J. Gen. Physiol.* **11,** [illegible] 41(192[illegible] [illegible]ection of concn. p. ds. across the skin of the frog is related to t[illegible] [illegible] soln. On the alk. side of an isoelec. point, the dil. soln. is positi[illegible] [illegible]gative. If the p_H is suddenly lowered from the alk. to the acid [illegible] of th[illegible] [illegible], a change in polarity may occur in a few secs. The effect i[illegible] [illegible] series of unbuffered solns. at different p_H values is applied reve[illegible] [illegible]btained, with concns. of KCl between 0.1 and 0.001 N, the reve[illegible] [illegible] p_H 4.1 and 4.8. The electromotive behavior of frog skin is c[illegible] [illegible]olyte or group of ampholytes probably protein in nature. On b[illegible] [illegible] points, frog-skin membranes, like protein membranes, behave a[illegible] [illegible] movement through them of ions having the same sign as the membrane [illegible] permitting movement of ions in the opposite direction. This is probably d[illegible] [illegible]lectrostatic effect between the charged surfaces and the ions in soln. C. H. RICHARDSON

Hemolysis by saponin and sodium tauro[illegible]chol[illegible] with special reference to the series of Ryvosh. J. H. YEAGER. New York Univ. *J. Gen.* [illegible]*ysiol.* **11,** 779-87(1928).—The series of Ryvosh (*C. A.* **1,** 870) consists of certain [illegible]mals arranged in order of resistance of their cells to saponin hemolysis [illegible] expts., the series of Ryvosh was obtained when hemolysis of red blood cells was ac[illegible]plished with saponin, but not with Na taurocholate. Probably saponin [illegible] hemolytic agent which produces the series of Ryvosh, whereas Na taurocholate, [illegible] [illegible] lysin, and a no. of glucosides other than saponin give a different resistance s[illegible]. Cf. Koller and Lázár, *C. A.* **21,** 1837; Ponder and McLachlan, *C. A.* **22,** 262. C. H. RICHARDSON

Electric impedance of suspensions of spheres. K[illegible] COLE. Cruft Elec. Lab. and Harvard Univ. *J. Gen. Physiol.* **12,** 2[illegible] 36(1928).—[illegible] [illegible]neral math. expression has been derived for the elec. impedance of a suspension of spheres each with a homogeneous, non-reactive interior and a thin surface layer with both resistance and reactance. Its applications and limitations are discussed. **Electrical impedance of suspensions of Arbacia eggs.** *Ibid* 37 51. T[illegible] specific resistance of the interior of the egg is about 90 ohm cm. or 3.6 times that o[illegible] [illegible]a water. The impedance of the surface of the egg is probably similar to that of a "[illegible]rization capacity." Interior resistance and surface impedance do not appear to be [illegible]lated either to membrane formation or cell division. An app. for the measure[illegible]nt of the elec. impedance of suspensions of *Arbacia* eggs in sea water to alternatin[illegible] currents (1000-15,000,000 cycles per sec.) is described. C. H. RICHARDSON

Dark adaptation in Agriolimax. W. J. CROZIER AND W. WOLF. Harvard Univ. *J. Gen. Physiol.* **12,** 83-109(1928).—Largely physiol. but the assumed underlying photochem. reactions are considered. C. H. RICHARDSON

Oxidation-reduction equilibria in biological [illegible]stems. I. Reduction potentials of sterile culture bouillon. C. B. COOK[illegible] Columbia Univ. *J. Gen. Physiol.* **12,** 139-46(1928).—Sterile bouill[illegible] [illegible]ntains [illegible] autooxidizable substance, the oxidation of which is accompanied by the reducti[illegible] of electromotively active substances such as glutathione or indicator dye. T[illegible] auto[illegible]xidizable substance may exhibit irreversible oxidation and therefore might show no measurable oxidation potential. The

limiting value of negative potential shown by sterile bouillon at p_H 7.6 is similar to that observed for reduced glutathione and for boiled yeast cells in the presence of glutathione. Reduction occurs so long as a certain concn. of glutathione in oxidized form is present and does not proceed below the level of the potential at which glutathione is completely reduced. The expts. suggest that in the catalytic oxidation of some autoöxidizable substances by glutathione, the oxidized form of the latter is active and the change, disulfide to sulfhydryl, is the mechanism for electron transfer. The observed potentials and the oxidation of the autoöxidizable substance measure the free energy of reduction of glutathione or other electromotively active substance. Reduction does not proceed to a more negative level because no system exists to yield measurable potentials. The capacity of bouillon to combine with O_2 is not exhausted after 9 months exposure to air or after successive aerations and subsequent reductions of methylene blue. This suggests that considerations other than those discussed may be required to interpret the observed potentials. Bouillon probably does not contain electromotively active substances in equil. with O_2 according to the equation: oxidized form $\rightleftharpoons O_2$ + reduced form. Degradation products of hemoglobin may be present and provide a dissociable mechanism through which removal of O_2 affects the potentials. The removal of O_2 by deaeration or by combination with some bouillon constituent shows a reduction intensity of [illegible] v., a potential level which would probably be attained by any other O_2 withdrawing process. The development of this reduction intensity in bacterial cultures cannot, therefore, be attributed to the activity of living cells. The potential relations of bouillon are probably not peculiar to that system but involve factors concerned in other biol. solns. A similar study is being made on the growth of *B. typhosus* in sugar-free bouillon. C. H. Richardson

Mechanism of action of the oxidizing catalyzers. L. Stern. *Compt. rend. soc. biol.* **98,** 1288–90(1928).—*Oxidases*, or better, oxidation reduction enzymes, act equally well in the presence of O and of some other acceptor of H; they do not show a specificity for a substratum bearing the OH [illegible] of water. *Oxydones*, on the contrary, can act only in the presence of active O, which cannot be replaced by another acceptor of H (such as methylene [illegible] specific [illegible] is thus shown toward a substratum contg. the H of H_2O. L. W. Riggs

Influence of diatomaceous earth on the growth of tissue cultures. B. M. Soloviev and A. A. Pinus. *Compt. rend. soc. biol.* **99,** 546–7(1928).—Tests with spleen tissue of white rats in horse serum showed that the admn. of diatomaceous earth stimulates the proliferation of the cellular elements. L. W. Riggs

Hemolysis in vitro by sparteine sulfate. P. Dobi[illegible] *Compt. rend. soc. biol.* **99,** 578–9(1928).—The red corpuscles of sheep blood were washed 4 times and were suspended in a 1 to 8 diln. of physiol. saline soln. [illegible] sparteine sulfate added to this suspension in amts. of 0.032 to 0.064% caused hemolysis of the red corpuscles at room temp. in 15 to 30 min. L. W. Riggs

Action of trypsin. Determination of variations of the course of tryptic digestion and the influence of the reaction of the medium on the process. Yvonne Schaeffer. *Compt. rend. soc. biol.* **99,** 581–[illegible](192[illegible]).—The detn. of the variations of p_H in the course of action of trypsin (pancreatin [illegible]) on solns. of gelatin and casein permits an easy following of the process. [illegible] optimum reaction, which is very limited, corresponds to a p_H of 8.0. The variation [illegible] p_H in the course of the digestion do not appear to influence the velocity of the phenomena, at least when digestion is rapid. Starting with a p_H of 8.0 and a temp. of 37.5° there is a rapid fall of p_H to about 7.4 during the first 20 min. and a slower fall during the next 40 [illegible] after which the p_H remains nearly const. L. W. Riggs

The reaction between sugar and amino acids. IV. Hans v. Euler, Ester Eriksson and Edv. Brunius. Univ. Stockholm. *Svensk Kem. Tid.* **40,** 163–71 (1928) (In German.).—Glucose and glycocoll [illegible] at p_H 8 to 10 give a product which reduces methylene blue. The reaction is measured by the time required for decolorizing the dye (Borsook and Wasteneys, C. A. **20,** 1635). The reaction increases with time of incubation and p_H. Glucose alone at p_H 9 and over decolorizes methylene blue from which it is inferred that the process is dependent on 2 facts: 1st, a change in the glucose by alkali; 2nd, the product of this change reacting with the amino acid. Replacing the alkali and amino acid with NH_3 does not give the methylene blue reducing substance, but hexaphosphates do. The influence of ultra-violet light was very slight. A. R. Rose

The biological oxidation and Warburg's respiratory enzyme. Carl Oppenheimer. *Chem.-Ztg.* **52,** 709–11(1928).—Survey of H. Wieland's and O. Warburg's theories of the biol. oxidation; neither one explains satisfactorily all the phenomena encountered

cytes and quartz particles. The latter two substances have the same velocity in this medium. The abs. viscosities are only slightly decreased by the presence of the gel. In stiffer gels, leucocytes, red blood cells and quartz particles move with equal velocity. When the gels are mechanically softened, the red blood cells resume their independent velocity of migration. Cataphoretic movement of particles in gelatin gels is different from that produced by magnetic force or the force of gravity. The mech. nature of obstruction to the cataphoretic migration of leucocytes and red blood cells in fibrin gels is described. Polymorphonuclear leucocyte emigration and migration are probably dependent upon p. ds. in the capillary wall. C. H. RICHARDSON

The mechanism of tonic immobility in vertebrates. H. HOAGLAND. Harvard Univ. *J. Gen. Physiol.* **11**, 715-41(1928).—Tonic immobility ("death feigning") in the lizard (*Anolis carolinensis*) was studied as a function of temp. The exptl. data which show the rate of change of the process when plotted as a function of temp. according to the Arrhenius equation are distributed in 2 straight line groups with temp. characteristics (μ) of 31,000 and 9000 cals., resp. The results are interpreted by assuming the release, through reflex simulation, of hormones, one effective between 5° and 35°, the other between 20° and 35°. They probably act as selective inhibitors of impulses from "higher centers," permitting impulses from tonic centers to pass to the muscles. Other physiol. information on this subject is given. C. H. RICHARDSON

The influence of p_H upon the concentration potentials across the skin of the frog. W. R. AMBERSON AND H. KLEIN. Univ. Penn. and Marine Biol. Lab., Woods Hole, Mass. *J. Gen. Physiol* **11**, 823-41(1928).—The production of concn. p. ds. across the skin of the frog is related to the p_H of the applied solns. On the alk. side of an isoelec. point, the dil. soln. is positive, on the acid side, negative. If the p_H is suddenly lowered from the alk. to the acid side of the isoelec. point, a change in polarity may occur in a few secs. The effect is reversible. When a series of unbuffered solns. at different p_H values is applied reversal curves may be obtained; with concns. of KCl between 0.1 and 0.001 *N*, the reversal points lie between p_H 4.1 and 4.8. The electromotive behavior of frog skin is controlled by an ampholyte or group of ampholytes probably protein in nature. On both sides of their isoelec. points, frog-skin membranes, like protein membranes, behave as if they inhibited the movement through them of ions having the same sign as the membranes, although permitting movement of ions in the opposite direction. This is probably due to the electrostatic effect between the charged surfaces and the ions in soln. C. H. RICHARDSON

Hemolysis by saponin and sodium taurocholate, with special reference to the series of Ryvosh. J. H. YEAGER. New York Univ. *J. Gen. Physiol.* **11**, 779-87(1928).—The series of Ryvosh (*C. A.* **1**, 870) consists of certain animals arranged in order of resistance of their cells to saponin hemolysis. In the present expts., the series of Ryvosh was obtained when hemolysis of red blood cells was accomplished with saponin, but not with Na taurocholate. Probably saponin is a special hemolytic agent which produces the series of Ryvosh, whereas Na taurocholate, bacterial lysin, and a no. of glucosides other than saponin give a different resistance series. Cf. Kofler and Lázár, *C. A.* **21**, 1837; Ponder and McLachlan, *C. A.* **22**, 262. C. H. RICHARDSON

Electric impedance of suspensions of spheres. K. S. COLE. Cruft Elec. Lab. and Harvard Univ. *J. Gen. Physiol.* **12**, 29-36(1928).—A general math. expression has been derived for the elec. impedance of a suspension of spheres each with a homogeneous, non-reactive interior and a thin surface layer with both resistance and reactance. Its applications and limitations are discussed. **Electrical impedance of suspensions of Arbacia eggs.** *Ibid* 37-54.—The specific resistance of the interior of the egg is about 90 ohm cm. or 3.6 times that of sea water. The impedance of the surface of the egg is probably similar to that of a "polarization capacity." Interior resistance and surface impedance do not appear to be related either to membrane formation or cell division. An app. for the measurement of the elec. impedance of suspensions of *Arbacia* eggs in sea water to alternating currents (1000-15,000,000 cycles per sec.) is described. C. H. RICHARDSON

Dark adaptation in Agriolimax. W. J. CROZIER AND W. WOLF. Harvard Univ. *J. Gen. Physiol.* **12**, 83-109(1928). Largely physiol. but the assumed underlying photochem. reactions are considered. C. H. RICHARDSON

Oxidation-reduction equilibria in biological systems. I. Reduction potentials of sterile culture bouillon. C. B. COULTER. Columbia Univ. *J. Gen. Physiol.* **12**, 139-46(1928).—Sterile bouillon contains an autoöxidizable substance, the oxidation of which is accompanied by the reduction of electromotively active substances such as glutathione or indicator dye. The autoöxidizable substance may exhibit irreversible oxidation and therefore might show no measureable oxidation potential. The

limiting value of negative potential shown by sterile bouillon at p_H 7.6 is similar to that observed for reduced glutathione and for boiled yeast cells in the presence of glutathione. Reduction occurs so long as a certain concn. of glutathione in oxidized form is present and does not proceed below the level of the potential at which glutathione is completely reduced. The expts. suggest that in the catalytic oxidation of some autoöxidizable substances by glutathione, the oxidized form of the latter is active and the change, disulfide to sulfhydryl, is the mechanism for electron transfer. The observed potentials and the oxidation of the autoöxidizable substance measure the free energy of reduction of glutathione or other electromotively active substance. Reduction does not proceed to a more negative level because no system exists to yield measurable potentials. The capacity of bouillon to combine with O_2 is not exhausted after 9 months' exposure to air or after successive aerations and subsequent reductions of methylene blue. This suggests that consideration other than those discussed may be required to interpret the observed potentials. Bouillon probably does not contain electromotively active substances in equil. with O_2 according to the equation: oxidized form = O_2 + reduced form. Degradation products of hemoglobin may be present and provide a dissociable mechanism through which removal of O_2 affects the potentials. The removal of O_2 by deaeration or by combination with some bouillon constituent shows a reduction intensity of —0.060 v, a potential level which would probably be attained by any other O_2-withdrawing process. The development of this reduction intensity in bacterial cultures cannot, therefore, be attributed to the activity of living cells. The potential relations of bouillon are probably not peculiar to that system but involve factors concerned in other biol. solns. A similar study is being made on the growth of *B. typhosus* in sugar-free bouillon. C. H. Richardson

Mechanism of action of the oxidizing catalyzers. L. Stern. *Compt. rend. soc. biol.* **98,** 1288-90(1928).—*Oxydases*, or better, oxidation-reduction enzymes, act equally well in the presence of O and of some other acceptor of H; they do not show a specificity for a substratum bearing the OH group of water. *Oxydones*, on the contrary, can act only in the presence of active O, which cannot be replaced by another acceptor of H (such as methylene blue); specificity is thus shown toward a substratum contg. the H of H_2O. L. W. Riggs

Influence of diatomaceous earth on the growth of tissue cultures. B. M. Soloviev and A. A. Pinus. *Compt. rend. soc. biol.* **99,** 546-7(1928).—Tests with spleen tissue of white rats in horse serum showed that the addn. of diatomaceous earth stimulates the proliferation of the cellular elements. L. W. Riggs

Hemolysis in vitro by sparteine sulfate. P. Dobel. *Compt. rend. soc. biol.* **99,** 578-9(1928).—The red corpuscles of sheep blood were washed 4 times and were suspended in a 1 to 8 diln. of physiol. saline soln. Sparteine sulfate added to this suspension in amts. of 0.032 to 0.064% caused hemolysis of the red corpuscles at room temp. in 15 to 30 min. L. W. Riggs

Action of trypsin. Determination of variations of the course of tryptic digestion and the influence of the reaction of the medium on the process. Yvonne Schaeffer. *Compt. rend. soc. biol.* **99,** 581-4(1928).—The detn. of the variations of p_H in the course of action of trypsin (pancreatin, O'Bailly) on solns. of gelatin and casein permits an easy following of the process. The optimum reaction, which is very limited, corresponds to a p_H of 8.0. The variations of p_H in the course of the digestion do not appear to influence the velocity of the phenomena, at least when digestion is rapid. Starting with a p_H of 8.0 and a temp. of 37.5°, there is a rapid fall of p_H to about 7.4 during the first 20 min. and a slower fall during the next 40 min. after which the p_H remains nearly const. L. W. Riggs

The reaction between sugar and amino acids. IV. Hans v. Euler, Ester Eriksson and Edv. Brunius. Univ. Stockholm. *Svensk Kem. Tid.* **40,** 163-71 (1928). (In German.)—Glucose and glycocoll mixts. at p_H 8 to 10 give a product which reduces methylene blue. The reaction is measured by the time required for decolorizing the dye (Borsook and Wasteneys, *C. A.* **20,** 1635). The reaction increases with time of incubation and p_H. Glucose alone at p_H 9 and over decolorizes methylene blue from which it is inferred that the process is dependent on 2 facts: 1st, a change in the glucose by alkali; 2nd, the product of this change reacting with the amino acid. Replacing the alkali and amino acid with NH_3 does not give the methylene blue reducing substance, but hexaphosphates do. The influence of ultra-violet light was very slight. A. R. Rose

The biological oxidation and Warburg's respiratory enzyme. Carl Oppenheimer. *Chem.-Ztg.* **52,** 709-11(1928).—Survey of H. Wieland's and O. Warburg's theories of the biol. oxidation; neither one explains satisfactorily all the phenomena encountered

within this process. The behavior of Warburg's respiratory enzyme is described.
G. Schwoch

Potassium thiocyanate and the diastatic action of saliva and plant diastases. L. R. Johnson and A. Wormall. *Proc. Leeds Phil. Lit. Soc., Sci. Sect.* **1**, Pt. VII, 318–24(1928).—It is not likely that the KCNS present in human saliva is a waste product of detoxication or that it functions as a bactericide. J. and W. believe that its functions are those of an accelerating agent for the action of the diastatic enzymes. For the expts., dialyzed, dild. saliva was allowed to act upon solns. contg. starch, phosphate buffer at p_H 6.7, and varying amts. of KCNS. The temp. was 37°. The rate of digestion of the starch was followed qualitatively by adding I soln. to samples taken at certain intervals and noticing the coloration. The results show that small concns. of KCNS, even such small concns. as may be present in the human saliva, have a distinct accelerating influence on the hydrolysis of starch, as far as the amylolytic action of the enzyme is concerned. Also when NaCl, the addn. of which alone speeds up the reaction, was added to give the optimum concn. of 0.1%, the effect of KCNS could still be observed. Expts. with an enzyme prepn. obtained by pptg. saliva with alc. and dissolving the ppt. in H_2O gave results similar to those obtained with ordinary dialyzed saliva. When glycogen or dextrin was used as substrates, the effect of KCNS was less pronounced. For measuring the accelerating effect of KCNS on the saccharogenic action of saliva, the expts. were carried out similarly as reported above; but instead of the coloration, the amt. of reducing sugar was detd. after a certain time. Using starch, glycogen and dextrin as substrates, none or only a very slight increase of the sugar concn. was seen. KCNS also accelerates the hydrolysis of starch caused by plant diastases, as seen in the expts. with com. malt diastase and a prepn. from potatoes; these findings probably are related to the observation that KCNS has a stimulating influence on the germination of potatoes and barley.
G. Schwoch

Toxicity of nascent elementary tellurium and selenium for enzymes. Richard Labes. Univ. Bonn. *Arch. exptl. Path. Pharm.* **133**, 57–62(1928).—Enzymes are inactivated by elementary Te and Se. G. H. S.

Studies on alcohol. VI. Effect on the action of pepsin. G. Franzen. Univ. Jena. *Arch. exptl. Path. Pharm.* **133**, 111–20(1928).—When added to artificial pepsin digestion prepns. pure EtOH stimulates protein cleavage. Although stimulating in its action in concns. up to 11%, the max. effect is exerted at a 4% concn., and even 30% alc. does not prevent peptic digestion. Wine and beer act similarly, the effect being proportionate to their alc. content. G. H. S.

Relation of irradiation to the threshold of stimulation in the heart. H. Zwaardemaker. *Arch. ges. Physiol.* (Pflüger's) **217**, 1–10(1927).—The inner stimulus for excitation of the heart is about 1 mikroerg per g. per sec. of heart substance. It would appear to be more valid to express the intensity of the irradiation in terms indicating the strength of the prepn. rather than in ergs. Only when the processes of Ra catalysis and origin of radioactive substance are better understood can precision be reached in estimations expressed in ergs. G. H. S.

The nomenclature of biochemistry; a pleasing reform. C. Béguin. *Schweiz. Apoth. Ztg.* **66**, 193–7(1928).—The nomenclature of carbohydrates (cf. Bertrand, *C. A.* **21**, 3376), fats, proteins and sol. enzymes as adopted by the Intern. Union of Pure and Applied Chemistry in 1927, is explained (cf. *C. A.* **21**, 920, 2001, 2482). A list of the bulletins issued is added. S. Waldbott

Role of hexosemonophosphate in enzymic degradation of sugar. Hans v. Euler and Karl Myrbäck. Univ. Stockholm. *Ann.* **464**, 56–69(1928).—The mechanism of the fermentation of dextrose is probably as follows: Under the influence of a synthetic enzyme, phosphatase, Robinson's hexosemonophosphate is formed but no free phosphate or CO_2 appears. The monophosphate, under the influence of a "mutase" and the cozymase, undergoes conversion, half into alc. and CO_2 and half into hexosediphosphate. The latter is converted by a phosphatase into a hexose (levulose?) which enters into the chain of processes given above. The velocity of fermentation of monophosphate by dried yeast is the same as that of a mixt. of equiv. quantities of dextrose and phosphate. A method is described for the detn. of mono- and diphosphate during the course of fermentation. Most prepns. of dextrose monophosphate using dried yeast give a product with $[\alpha]_D$ about 26° (Ba salt, 13°) but when a very strongly phosphatizing yeast was used the product had $[\alpha]_D$ 63° and is probably distinct from Robinson's material. C. J. West

Intracellular hydrogen-ion concentration. I. Methods. Juntaro Ogawa. Imp. Univ., Tokyo. *Proc. Imp. Acad.* **4**, 76–8(1928).—The intracellular H-ion concn. is

detd. by a slight modification of Schmidtmann's method (injection of indicator into the cell) and the results are compared with those obtained by Graff's method. The intracellular p_H of animal tissues decreases fairly rapidly after they have been removed from the body. II. Entamoeba histolytica and E. coli. *Ibid* 79–81.—The p_H of the protoplasma of *E. histolytica* and *E. coli* usually lies between 6.0 and 7.0.
C. J. West

Reaction of tissues. II. Hydrogen-ion concentration in the tissue during experimental acidosis and alkalosis. Juntaro Ogawa. Imp. Univ., Tokyo. *Proc. Imp. Acad.* (*Japan*) **4**, 82–3(1928); cf. *C. A.* **22**, 3928.—When acidosis is produced in an animal, whether by nephrectomy or by the injection of acids, the intracellular p_H decreases and it increases when alkalosis is produced by the administration of sufficient alkali. Injection of insulin increases the intracellular p_H. C. J. West

Lazarev, P. P.: **Théorie ionique de l'excitation des tissus vivants.** Coll. de Monographies scientifiques étrangères. Paris: A. Blanchard. 240 pp. F. 40.

Lipase. Shozo Yamamoto. U. S. 1,687,050, Oct. 9. Castor bean refuse is subjected to fermentation, soy bean refuse is added, and the fermentation is continued at a temp. of about 30–40° until protein material in the refuse is converted into a "yeast-like substance," the latter is dissolved by immersing the material in water, and lipase is pptd. from the resulting soln. by use of HOAc.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Determination of albumin and globulin in urine. A. Hiller. *Proc. Soc. Exptl. Biol. Med.* **24**, 385–6(1927).—One mg. of biuret gives a color equal to 0.924 mg. of urinary proteins treated with alkali and $CuSO_4$ as described by Autenrieth. The standard soln. is made by dissolving 0.4 g. of biuret in H_2O and dilg. to 150 cc. Five cc. contg. 13.33 mg. of biuret is colorimetrically equiv. to 12.3 mg. of urinary proteins. *For total protein*, enough urine to contain 8 to 20 mg. is pptd. with an equal vol. of 10% CCl_3COOH. The ppt. is redissolved in 3% NaOH, treated at 10 cc. vol. with 0.25 cc. of 20% $CuSO_4.5H_2O$, and compared with 1 cc. of the biuret standard similarly treated. Globulins are pptd. by treating the urine at 38° with an equal vol. of 44% Na_2SO_4. In the filtrate the albumin is detd. according to the method for total proteins. Globulins are calcd. as total protein minus albumin. C. V. B.

Estimation of the acid-combining capacity of a protein by means of the interferometer. Arthur W. Thomas and Charles W. Mayer. Columbia Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 667–9(1928).—In using a differential refractometer (interferometer) capable of measuring small changes in *n* to which an immersion refractometer is insensitive, it was found that the *n*s of mixed solns. of gelatin and of HCl are not additive. However, the refraction of mixed solns. of gelatin chloride and of HCl are additive. When a soln. of gelatin is titrated with an acid, an abrupt change in slope of the curve (refraction as function of acid added) is noted at the stoichiometric point. This is also the case when an amino acid is similarly titrated. C. V. B.

The grading of collodion membranes by means of ethylene glycol. Ada M. Field and Arthur W. Thomas. Columbia Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 679(1928); cf. Pierce, *C. A.* **22**, 604.—Description is given of mechanisms involved in grading collodion membranes by means of ethylene glycol and the alc. retained in the membranes after 24 hrs., drying. C. V. B.

A device for determining refractory period of the mammalian heart during normal sinus rhythm. Harold A. Wheeler and E. Cowles Andrus. John Hopkins Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 695–6(1928).—An app. is described which utilizes the action current after amplification, and with which it is possible to interrupt the sinus rhythm at any interval following a normal excitation. C. V. B.

Extraction of ovarian hormone from urine. C. D. Veler and Edward A. Doisy. St. Louis Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 806–7(1928).—A method is described for extn. and purification of the ovarian hormone from urine. This hormone is ex-

creted during pregnancy, and this elimination appears to cease soon after delivery.
C. V. B.

Determination of stercobilin. A. BAREGGI. *Folia clin. chim. micro.* **1**, 194-7 (1926).—According to Pietra and Bozzolo (*C. A.* **19**, 2965), stercobilinogen may be detd. by mixing 1 g. of the feces with 50 cc. of 95% alc., treating with an oxidizing agent (5-6 drops of HNO_2-HNO_3 and 11-12 drops of Obermeyer's reagent) to complete the transformation of stercobilinogen into stercobilin, and heating the liquid to the b. p. for 30 min. Of the clear decanted ext. 1 cc. is employed for the detn. by the fluorescence method, Nencki's reagent being used. B. considers that this method does not give accurate results and that it may be vitiated by the presence of bilirubin. Use of the spectroscopic method is recommended, the liquid being continuously dild. with alc. until the characteristic absorption band of stercobilin disappears, and it is considered advisable to take 5 g. instead of 1 g. of the sample. The Riva-Zoia method, in which chloroform is used for extg. the feces, gives results about one-half of those furnished by the Pietra and Bozzolo method, but serves well for ordinary clinical purposes. B. C. A.

The determination of heart-stroke-volume by means of ethyl iodide. GUNTHER LEHMANN. Kaiser-Wilhelm-Inst. für Arbeitsphysiol., Berlin. *Arbeitsphysiol.* **1**, 114-29(1928).—In studying the method of Henderson and Haggard (cf. *C. A.* **19**, 3506) it was found that EtI was sol. in water and was absorbed by rubber tubing. The air current in which the subject respired was drawn through a glass tube by a pump and the EtI vaporized from a glass container by positive pressure. The iodide in the expired air and alveolar air was absorbed by an aq. soln. of $AgNO_3$ and weighed as AgI (method of Ziesel). As the author considered he obtained too high values, he then detd. the distribution coeff. by means of an artificially perfused heart-lung prepn. from cats or rabbits, using blood at first, and later, horse plasma. The av. coeff. was 3.8. The value for plasma was the same by an *in vitro* method, and for blood between 5.5 and 8.5. Since EtI was not completely decomposed by blood, it is not suitable for the detn. of heart-stroke-vol. T. M. CARPENTER

A colorimetric method for the determination of methylglyoxal, dihydroxyacetone and glyceraldehyde. ERICH BAER. Kaiser-Wilhelm-Inst. für Arbeitsphysiol., Berlin. *Arbeitsphysiol.* **1**, 130-5(1928).—The method of Mendel and Goldscheider (cf. *C. A.* **19**, 3504) was applied to the detn. of methylglyoxal, dihydroxyacetone and glyceraldehyde. The 3 substances were detd. with sufficient accuracy in a concn. to 4 mg. % or 0.02 mg. absolute. T. M. CARPENTER

The influence of phenol and of formaldehyde on the preservation of some biological reagents. PIETRO RINALDI AND NICOLA SETTE. *Annali igiene* **37**, 446-61; *Chem. Zentr.* **1927**, II, 1735.—A study of the effect of PhOH and of HCHO on sheep blood corpuscles, hemolysin, complements, antigens, vaccines, agglutinins and sera showed that PhOH is preferable in every way to HCHO as a perserving agent. Even PhOH, however, impairs the stability of the action of antibodies. C. C. DAVIS

Has the addition of sodium citrate an influence on the customary carbon monoxide tests? HEINZ KOCKEL. Universitätsinstitut gericht. Med. in Innsbruck. *Wiener klin. Wochschr.* **41**, 1310-1(1928).—The addn. of enough Na citrate to prevent clotting had no effect on tests for CO. D. B. DILL

A simple and practical method of preserving anatomical specimens. ROBERTO MAGNANIMI. Univ. Pavia. *Arch. farmacol. sper.* **45**, 92-5(1928).—The method consists simply in suspending a wad of absorbent cotton satd. with $CHCl_3$ in the jar or container in which the anatomical specimen is to be preserved. The external form, color and histological structure of the specimen remain unaltered for a considerable time. A. W. DOX

Modification of the Widmark micro-method of determining alcohol in the blood. A. GALAMINI AND L. BRACALONI. Univ. Rome. *Arch. farmacol. sper.* **45**, 97-112 (1928).—The modification consists essentially in the use of a flask to the stopper of which is attached a rod terminating in a container for the sample and carrying a holder for the 0.1 cc. micro-pipet. In the bottom of the flask is placed 1 cc. 0.01 *N* $K_2Cr_2O_7$ in H_2SO_4, the stopper put in place and the flask heated 2 hrs. in a water bath at 55-60°. The EtOH thus evapd. from the sample reacts with the $K_2Cr_2O_7$ and the excess of the latter, after diln. with H_2O, is detd. by adding KI and titrating with $Na_2S_2O_3$. A. W. DOX

A color reaction for creatine and urea. EMILIO PITTARELLI. *Arch. farmacol. sper.* **45**, 173-6(1928).—The Weyl reaction for *creatinine* is an evanescent red color produced by addn. of Na nitroprusside. In the presence of an oxidizing agent, prefer-

ably $Na_2S_2O_4$, *creatine* on the other hand gives a permanent color. This reaction is sensitive 1:50,000. The color is stable to alkali, but is destroyed by acid and then only partially restored by again making alk. It is insol. in org. solvents and is not pptd. by salts of heavy metals. It is stable to oxidizing agents but destroyed by reducing agents. To perform the creatine test, make 5 cc. of the sample strongly alk., add about 0.05 g. Na nitroprusside and 0.1 g. $K_2S_2O_8$. A red color appears after 20–30 sec. and reaches its max. intensity in 2–3 min. If an instantaneous reaction is desired add a trace of $K_3Fe(CN)_6$. Creatinine and creatine may be identified in a mixt. of the 2. The evanescent Weyl reaction indicates the former, and the subsequent restoration of color by addn. of $K_2S_2O_8$ indicates the latter. Urea gives a similar reaction which is sensitive only 1:500, a concn. greater than that encountered in body fluids other than urine. A. W. Dox

A modification of the phenolized gelatin technic for the mounting of microscopic preparations of yeasts and algae. H. Kufferath. *Rev. hyg. med. prev.* **50**, 638–40 (1928).—A formula consisting of 7 g. gelatin dissolved in 42 cc. H_2O, 50 cc. glycerol and 1 g. phenol. To this melted mixt. add 0.3–0.5% $Cu(C_2H_3O_2)_2$, filter while hot. The $Cu(C_2H_3O_2)_2$ is for the purpose of retaining the natural green colors of the prepns. C. R. Fellers

The effect of preliminary treatment (fixing fluids) on staining properties of the tissues. A. V. Tolstoouhov. *Stain Tech.* **3**, 49–56(1928).—Staining properties depend primarily on the chem. compn. of the tissues. By applying mixts. to tissues of basic and acid dyes such as methylene blue and eosin Y, at different p_H values, differences in the isoelec. points of the nuclei and cytoplasm of different tissues were found. Many fixing fluids gave very stable compds. with tissue proteins and thus permanently changed, in many cases, the chem. compn., *i. e.*, staining properties, of the tissues. An example is the reaction of CH_2O with NH_2 groups of the amino acids of proteins; this makes the tissue proteins more acid, that is, it moves the isoelec. point of the proteins toward a lower p_H value. The same is true of polybasic acids. Bivalent heavy metals such as Hg combine with COOH groups and move the isoelec. point of the proteins toward a higher p_H. C. R. Fellers

A spectrophotometric method of studying hemoglobin and other colored substances in solution. George E. Davis. Ia. State Coll., Ames. *Proc. Iowa Acad. Sci.* **34**, 279–80(1927); cf. *C. A.* **21**, 3638.—An investigation was carried out to det. the possibilities of applying spectrophotometric methods to the problem of estg. the concn. of hemoglobin in blood. The concn. of a substance in soln. can easily be detd. from its transmission of some particular wave length, providing the absorption ratio for that wave length is known. A late model direct-reading spectrophotometer was used. The method was found to be fairly accurate and simple and should prove valuable in other phys. investigations involving the study of spectral transmission curves of various colored substances. Some interesting irregularities in the shape of the spectral transmission curve in one of the absorption bands of oxyhemoglobin were observed. W. G. Gaessler

A comparison of the quantitative methods for the bilirubin of the blood. H. F. Shattuck, J. A. Killian and M. Preston. *J. Lab. Clin. Med.* **12**, 802–10(1927); *Physiol. Abstracts* **12**, 561.—Parallel detns. of serum bilirubin were made in 150 cases showing varying degrees of jaundice by the icterus index of the blood serum and the modified quant. van den Bergh method. The detn. of the icterus index was the more reliable, the van den Bergh technic being unsatisfactory in 50% of the cases within the zone of latent jaundice. H. G.

Micro-method for the colorimetric determination of urea in blood. Florence Beattie. Queen's Univ., Belfast. *Biochem. J.* **22**, 711–2(1928).—0.5–1.0 cc. of blood is deproteinized. To 1 vol. blood add 7 vols. distd. water, 1 vol. 10% Na tungstate and 1 vol. $^2/_3$ *N* H_2SO_4. Shake and filter. Place 1 cc. filtrate (= 0.1 cc. blood) in a centrifuge tube, add 1 cc. glacial acetic acid and 0.2 cc. of 5% xanthhydrol in MeOH, allow to stand 5 min., stir, allow to settle for $^1/_2$–1 hr. or centrifuge for 20–30 min. Filter by suction using a Gooch crucible. Wash alternately 3 times with 2 cc. CH_3OH and distd. water. Place a small receiving tube inside the flask to catch the succeeding filtrate. Pour 5 cc. 50% H_2SO_4 into a crucible. When the ppt. has dissolved, attach the pump and draw the yellow soln. into a receiving tube. Wash with 4 cc. H_2SO_4. Remove the tube and make up to 10 cc. in a graduated test-tube. Compare in a colorimeter with standard. (The standard is made by dilg. 0.4 cc. of 0.01% urea with water. Then adopt a procedure as in blood filtrate—1 cc. urea, 1 cc. acetic acid, 0.2 cc. of 5% CH_3OH soln. of xanthhydrol. The ppt. is centrifuged, filtered, washed, and dissolved in 10 cc. of 50% H_2SO_4.) The standard corresponds to 0.04 mg. urea in the 10 cc. of acid

used. Calcn.: $10/x \times 40$ = mg. urea per 100 cc. blood, where the standard is set at 10 mm. and x = length of the column of soln. of unknown. BENJAMIN HARROW

Vital staining of normal and malignant cells. I. Vital staining with trypan blue and the cytoplasmic inclusions of liver and kidney cells. R. J. LUDFORD. Univ. London. *Proc. Roy. Soc.* (London) B103, 288–301(1928).—When animals are stained intravitally by means of trypan blue, cells of the liver and kidney contain dye droplets assocd. with the mitochondria and Golgi app. No definite relationship apparently exists between the droplets and mitochondria. The droplets appear in relationship with the Golgi app., and break loose into the cytoplasm when formed; this procedure resembles the formation of secretion granules in gland cells. These findings suggest the functional relationship between mitochondria and Golgi app. Syntheses by enzymes occur at the mitochondrial-cytoplasmic surface; the resulting products diffuse into the cytoplasm and are concd. at the surface of the Golgi app. preliminary to their elimination from the cell. JOSEPH S. HEPBURN

Colorimetric determination of blood pigment in comparison with the value obtained by determination of the oxygen capacity of the blood. JAROSLAV MĚLKA. Komenský Univ., Bratislava. *Bratislav. Lekárske Listy* **6**, 113–22(1926).—Blood pigment was detd. in 2 ways: (1) calcd. from the O_2 capacity detd. by Barcroft's differential manometer, using venous blood, and (2) by the usual colorimetric method, using capillary blood. The values obtained colorimetrically were always lower than those calcd. from O_2 capacity, the differences being smaller when venous blood was used for both tests. Conclusion: The lower values in the colorimetric test are due in part to admixt. of tissue lymph with the blood. WILLIAM J. HUSA

New method for identification of insoluble blood. FRANCESCO PISANI. *Boll. chim. farm.* **67**, 449–51(1928). See *C. A.* **22**, 2584. MARY JACOBSEN

Urinalysis in general practice. HENRY A. ELLIS. *Am. Med.* **34**, 447–56(1928).—Discussion. FRANCES KRASNOW

Determination of quinine in blood. M. M. PANTSCHENKOW AND A. A. KIRSTNER. Med. Klinik der I Staats-univ. in Moskau. *Arch. Schiffs-Tropen-Hyg.* **32**, 137–40 (1928).—The ether ext. is treated with 1–2 cc. dil. H_2SO_4, warmed slightly, set in the light of a Bachschen quartz lamp and the resulting fluorescence matched against a quinine bisulfate standard treated in the same way. FRANCES KRASNOW

Is a chlorophyll-free diet necessary for the study of occult blood? Z. ERNST, B. V. PURJESZ, JR. AND L. ZILZER. *Arch. Verdauungs-Krankh.* **42**, 209–10(1928).—Chlorophyll has little influence on most of the blood reactions. Green plants as well as meat and fish affect the benzidine reaction and they should be omitted from the test diet. FRANCES KRASNOW

The repeated test-breakfast method in the study of the functions of the gastric cells. S. REISELMAN. Ukrainischen Staatsinstitut der Arbeitsmedizin. *Arch. Verdauungs-Krankh.* **42**, 211–24(1928). FRANCES KRASNOW

Liver-function test with "Bengalrot." I. SNAPPER AND S. C. M. SPOOR. *Arch. Verdauungs-Krankh.* **43**, 426–8(1928).—100 mg. "Bengalrot" in 10 cc. water (1.5 mg. per kg. body wt.) is injected intravenously and the patient kept in the dark. After 1 hr. a blood sample is obtained, oxalated, and centrifuged. After the addn. of a few drops of NaOH soln., a spectroscopic reading is taken. With the normal liver a 1:300,000 Bengal red value is obtained after 1 hr. Higher values indicate liver dysfunction. FRANCES KRASNOW

Improved procedure for the extraction of the ovarian hormone. II. Some corrections and additions. SIDNEY THAYER, C. N. JORDAN AND EDWARD A. DOISY. St. Louis Univ. *J. Biol. Chem.* **79**, 53–64(1928); cf. *C. A.* **20**, 3301.—In the prepn. of ovarian hormone care must be taken that the Et_2O and petroleum ether used in extns. contain no peroxides as destruction of the hormone by oxidation can readily occur. Storage of the hormone in solvents which may develop peroxides must also be avoided. The conversion of an alc. soln. of the hormone into a crystal-clear aq. soln. is a simple matter and is accomplished by merely dilg. it with an appropriate vol. of H_2O and distg. off the alc. The colloidal impurities are coagulated by addn. of a drop of dil. HCl followed by filtration through a thick layer of asbestos after several hrs. in a refrigerator. Details of the complete process of extn. are given. A. P. LOTHROP

Composition of bone. I. Analytical methods. M. J. SHEAR AND BENJAMIN KRAMER. Jewish Hosp., Brooklyn, N. Y. *J. Biol. Chem.* **79**, 105–20(1928).—With the methods described the CO_2 content of bone can be detd. with 20 mg. of bone powder and duplicate detns. of Ca and inorg. P require only 10 mg. The CO_2 content of the bone after extn. with an alc.-Et_2O mixt. is detd. in the Van Slyke manometric blood gas app.; the CO_2 is liberated by H_2SO_4 and detd. by absorption with alkali. For the

Ca and P detns. the bone powder is digested with HCl and the protein removed with CCl_3CO_2H; the Kramer and Tisdale procedure is used for estg. Ca and the Briggs-Bell-Doisy method for the P. These procedures were developed to permit the analysis of very small specimens of calcified tissues but they may also be used for detg. CO_2, Ca and P in solids other than bone. A. P. LOTHROP

The oxidation of dixanthydryl urea, a micro-method for determining urea. JAMES M. LUCK. Stanford Univ. *J. Biol. Chem.* 79, 211–9(1928); cf. *C. A.* 22, 2763.—A volumetric method for the estn. of urea is described in which the urea is pptd. as dixanthydryl urea. This compd. dissolves in H_2SO_4 to give a fluorescent yellow soln. which can be quant. titrated with $KMnO_4$. The method can be used with the H_2WO_4 blood filtrate, with urine, and with tissue exts. and 0.1 mg. of urea may be estd. with an exptl. error of about 5%. A. P. LOTHROP

A study of the estimation of chloride in blood and serum. D. WRIGHT WILSON AND ERIC G. BALL. Univ. of Pa. Med. School. *J. Biol. Chem.* 79, 221–7(1928).—More accurate and consistent results are obtained with the Van Slyke method (*C. A.* 18, 698) for chloride in blood or serum if aq. $AgNO_3$ soln. and HNO_3 are added separately instead of a soln. of $AgNO_3$ in HNO_3. A. P. LOTHROP

A comparison of p_H determinations as obtained by means of hydrogen electrode and colorimetric methods. CHARLES G. JOHNSTON. Univ. of Pa. Med. School. *J. Biol. Chem.* 79, 297–307(1928).—Cullen's, Hasting's modification of Cullen's, and Dale and Evans' colorimetric methods were compared with the H_2 electrode method in detg. the H-ion concn. of dog sera. The differences between the 2 types of methods were not const. and the corrections necessary were so variable that the colorimetric methods cannot be used if accurate comparisons of even individual detns. are to be made. It is doubtful if colorimetric methods should be used indiscriminately on all varieties of sera without adequate checking with the H_2 electrode. They should not be employed for a comparison of individual detns. of either human or dog bloods. They may be used for statistical studies on human blood from normal and certain groups of pathol. individuals with av. correction values. A. P. LOTHROP

The volume of the blood. I. The use of the thermocouple for determining the freezing point of a small quantity of fluid. DAN C. DARROW AND THOMAS E. BUCKMAN. *Am. J. Diseases Children* 36, 78–82(1928).—A thermoelec. method for the detn. of the f. p. of biological prepns. is described. Not more than 3 cc. quantities of fluid are required. The method is rapid and accurate within 0.004°. E. R. M.

A critical study of the portable Benedict apparatus. LUCIEN DAUTREBANDE. *Arch. intern. med. exptl.* 4, 327–34(1928).—A brief report of D.'s investigation of possible sources of error attending the use of the portable Benedict app. for the detn. of metabolic rate. E. R. MAIN

The reaction of the blood in sex determination. The significance of the permanganate mixture in the chemistry of the sex determination reaction. V. V. PRÁVDICZ-NEMINSKII. *Biochem. Z.* 192, 303–23(1928).—The Nanoilow reaction was performed only with the reagents without blood or any other fluid. By varying the amt. of HCl all gradations were obtained from the typical male reaction (complete discoloration) to the typical female reaction. This change is attributed to the actual formation of ozone and Cl_2 in the mixt. The former can be easily demonstrated when 3 drops of 9.52% HCl are mixed with 20–30 drops of 1% $KMnO_4$, by the blackening of a Ag plate, while the Cl_2 liberated can be detected by its characteristic odor or with $AgNO_3$. Thiosinamine is easily oxidized by $KMnO_4$. It easily binds the ozone and Cl_2 and thus promotes the reaction to completion. Dahlia is relatively stable to oxidation and is but very slowly acted upon by 0.1 *N* $KMnO_4$. But the $KMnO_4$-HCl mixt destroys the dye rapidly with formation of ozone and Cl_2 in the absence of org. substances, or when their concn. is relatively low. Thus, the "typical male reaction" of Nanoilow is produced. In the presence of easily oxidizable substances the dye is protected from oxidation and the "female reaction" results. It is not surprising, therefore, that sperm and spermin give the "female" reaction while it is not obtained with "ovarin." Their ability to prevent discoloration depends on their ability to become oxidized. The Nanoilôw reaction cannot therefore serve to identify directly the sex hormones. S. MORGULIS

Iodometric micro-determination of nitrogen by means of alkali hypobromite. TORSTEN THORELL. *Acta med. Scand.* 68, 305–35(1928).—Nothing new. The importance of a properly adjusted alky. for accurate results by the procedure is emphasized. S. MORGULIS

An iodometric method for determining homogentisic acid in urine. ERNST METZ. *Biochem. Z.* 190, 261–4(1927).—The detn. depends upon the oxidation of homogentisic acid to quinoneacetic acid by I in an alk. medium. The reaction is reversed in acid

soln. and the I set free by acid is titrated back with 0.1 N $Na_2S_2O_3$. The detn. is carried out as follows: to a soln. of homogentisic acid made alk. with $NaHCO_3$ or borax add 0.1 N I soln. until the blue reaction with starch is obtained. Acidify with dil. H_2SO_4 and titrate the I. Each cc. 0.1 N $Na_2S_2O_3$ corresponds to 8.487 mg. dry homogentisic acid, or 0.10 g. acid equals 11.783 cc. 0.1 N $Na_2S_2O_3$. In working with alkaptonuric urines 1–10 cc. is accurately measured and dild. with water to 10 cc. where necessary. This is made alk. as before. Add 1 cc. 1% starch soln. as indicator, and titrate with I. The acid should be added cautiously, and the foam may be broken with a little alc. S. MORGULIS

The use of Stolte's ashing method in microanalysis. CARLA EGG AND K. KLINKE. Physiol.-Chem. Anstalt, Univ. Basel. *Biochem. Z.* 191, 439–41(1928).—Stolte's method for ashing biological material gives absolutely reliable results also in the microanalysis of bases (Na, K). For the detn. of P, Cl and S the wet ashing method must still be used. S. MORGULIS

Biochemical preparation of a diglucide-monophosphoric ester. C. NEUBERG AND J. LEIBOWITZ. *Biochem. Z.* 193, 237–44(1928).—Under the influence of the lactic acid organism, *Bacillus Delbrücki*, a substance with a high sp. rotation (+55°) is produced which as the Ba salt has the composition: $C_{12}H_{21}O_{10}.PO_4Ba$, *i. e.*, a monophosphato ester of a diglucide. It is suggested that this is formed through the complete de-phosphorization of one and partial de-phosphorization of another of 2 mols. of hexose-diphosphate. It is known that enzymically both glucose and fructose may be formed from the hexose-diphosphate ester, and while in the nascent state these apparently combine into a diglucide. S. MORGULIS

A rapid method for determining organically bound iodine. G. PFEIFFER. *Biochem. Z.* 195, 128–33(1928).—The org. matter is digested with H_2SO_4-H_2O_2 whereby the I set free is collected in alkali. The oxidation does not require very high temp. so that there is little H_2SO_3 formed and therefore the alkali is not readily used up. Also there is no danger of HIO_3 formation since this is at once reduced to HI by the H_2SO_3 present in the digestion mixt. The detn. is very much simpler than the alkali hydrolysis usually employed and requires only about 40 min. and as much as 100 g. of substance can be worked over. The distillate is now neutralized with H_2SO_4 and filtered into a 250 cc. sepg. funnel. According to the amt. of I_2 expected, $CHCl_3$ is added, 1 cc. for every 200–300 γ (0.001 mg.), and a few cc. HNO_2 and the liberated I_2 is extd. by shaking. 100 γ I_2 can be very easily recognized in 10 cc. $CHCl_3$. The detn. is then carried out on 0.05–0.10 cc. amts. of the $CHCl_3$ by v. Fellenberg's colorimetric method. S. MORGULIS

Electrodialysis of serum. G. ETTISCH AND W. EWIG. *Biochem. Z.* 195, 175–88 (1928).—Fractionation of the serum globulin by electrodialysis should be carried out under the following conditions: undild. serum must be employed; large changes in reaction must be avoided; the temp. should be maintained below 36°; the fractionation should be carried out rapidly. The procedure is discussed for attaining these ideal conditions. Also, the use of an albumin-collodion membrane for the anode together with a parchment membrane is described, the former not being replaceable by a simple collodion membrane. S. MORGULIS

Urea determination in urine. MAX HOPF. *Biochem. Z.* 195, 206–9(1928).—Criticism of the urease method as recommended by Pincussen. The results are too low because of the failure to distil off the entire amt. of NH_3 in the prescribed time. By prolonging the distn. up to 50 min. results were obtained which checked well with Laubender's modification of Folin's $MgCl_2$ method for urea detn. S. MORGULIS

A new method for estimating the digestive action of enzymes according to the effect on elastin. JOSEF SCHNEIDER, JR., AND AUGUSTIN HÁJEK. Inst. of Tanning, Prague. *Biochem. Z.* 195, 403–14(1928).—Elastin is obtained from Ligamentum nuchae. The influence on the tryptic digestion of elastin of H-ion concn., duration of digestion, the size of elastin particles, temp., variable amts. of enzyme or of elastin was detd. S. MORGULIS

Micro-determination of non-protein nitrogen in blood by the sodium hypobromite method. RYUZO IWATZURU. Med. Akad., Osaka. *Biochem. Z.* 195, 442–8(1928).—This method does not present anything new, except that the use of Na tungstate in place of $CuSO_4$ is recommended in carrying out the digestion with acid. S. M.

The colorimetric determination of levulose in blood by means of diphenylamine. PAUL RADT. Krankenhaus Moabit, Berlin. *Biochem. Z.* 198, 195–203(1928).—One cc. of defibrinated blood or serum is added in a test tube to 1 cc. 4% HCl; then, with vigorous shaking, 2 cc. of 5% $HgCl_2$ are added. A protein-free filtrate is thus obtained, of which 0.5 or 1.0 cc. is used. For comparison 1 cc.

of 0.1% standard levulose soln. is taken. To each test tube are added 1 cc. 25% HCl and 0.1 cc. of a 20% alc. soln. of diphenylamine, and these are placed for 15 min. in a boiling water bath. After cooling 2 min. in water 1 and 5 cc. of amyl alc. are added to the standard and unknown tube, resp. The complete soln. of the ppt. in the amyl alc. is brought about by warming for 3 min. at 75°; after renewed cooling in water 1 and 5 cc. amyl alc. are again added, and following thorough mixing the colorless liquid under the alc. layer is carefully pipetted off. The inequality of color, the blood tube having a greenish tinge, can be corrected by the use of a filter under the colorimeter, for which purpose eosin is most suitable. It is stated that the results obtained by this procedure are qualitatively accurate. S. MORGULIS

Modification of the Salkowski reaction for the determination of cholesterol in blood serum. DORIS ABRAMSOHN. Inst. of Medicine, Leningrad. *Biochem. Z.* **198**, 233–40(1928).—The Krastelewsky modification of the Salkowskii reaction can be carried out at room temp. The phase of the yellow-orange coloration lasts 20–40 min., depending on the amt. of cholesterol, the end of this phase being marked by the appearance of a rose tone. This change in color is not due to the presence of H_2O. The best results are obtained with H_2SO_4 of sp. gr. 1.836. At the time of max. development of color intensity there is a state of equil. and passage from one layer to another is practically excluded, which insures the stability of the colorimetric tone. S. M.

A study in the variable factors in the use of Wright's stain. ROY F. FEEMSTER. Tulane Univ. *Ann. Internal Med.* **2**, 289–93(1928).—Distd. water is usually acid and should be buffered. Usually 30 cc. of 1% KH_2PO_4 and 20 cc. of 1% Na_2HPO_4 to a l. of distd. water are adequate. If the erythrocytes are too pink add more Na_2HPO_4, if not pink enough add more KH_2PO_4. The proper % of alc. in soln. 2 is 85 to 90. In old stains the concn. of pigment in soln. 1 may be too great. If so it will overstain with eosin. The staining time should not be less than 1 min. J. T. M.

The usefulness of the indole determination method of Kovács. E. LEHR. Staatlichen Veterinär-untersuchungsamt Potsdam. *Centr. Bakt. Parasitenk. Orig. I Abt.* **108**, 209–12(1928); cf. *Centr. Bakt. Parasitenk. I Abt. Ref.* **88**, 430(1928).—The superiority of the method does not hold in all cases, especially if only small quantities of indole are present. JOHN T. MYERS

The Ellermann method of granule staining. JOHANNES FIBIGER. Univ. Kopenhagen. *Folia Haematol.* **36**, 390–4(1928).—The method is useful in studying hyper- and metaplastic bone marrow or spleen, but care must be used and each specimen stained repeatedly, as the results are not always uniform. JOHN T. MYERS

A respiration apparatus for a metabolic study of the various subdivisions of the human race. FRANCIS G. BENEDICT. *Chinese J. Physiol. Report Series* **1928**, No. 1, 39–58.—The subject breathes through a rubber mouthpiece into a closed circuit of O-rich air. This closed circuit consists of a closed metal can, partly filled with soda-lime for the absorption of the CO_2 produced and covered with a light-wt. rubber bathing cap for the expansion and contraction of the air during respiration. The O consumed is replaced by O from a rubber bag. The O is satd. with water vapor by being passed through a moistening device. It is then metered through a pump of known and const. vol. of stroke. The expt. begins and ends with the bathing cap at a definite degree of distension, and the O introduced during the expt. is thus a measure of the O consumed by the subject. A simple O generator is described, with which O may be generated from a com. prepn. of Na_2O_2, when it is impossible to obtain cylinders of the compressed gas. But 2 measurements are needed, the no. of the pump strokes used in the expt. and the actual time elapsed. Details for testing the app. for tightness and for conducting a measurement are given. L. W. RIGGS

Different behavior of certain biliary acids in the classic color reactions. LOUIS CUNY. *Compt. rend. soc. biol.* **99**, 613–5(1928).—The Pettenkoffer reaction and its variants, performed in the usual manner, detect the biliary acids of the cholalic series which predominate in human bile. In the colorimetric estn. of biliary acids in general biology, account should be taken of other acids, such as desoxycholic, anthropodesoxycholic, hyoglycodesoxycholic and α-hyoglycocholic, which give fainter colors or none with this reaction. L. W. RIGGS

Method of testing liver functioning by means of Congo red. YOSHISHIGE NINOMIYA. *Tohoku J. Exptl. Med.* **11**, 151–87(1928).—The Congo red test is the best of the color tests for detg. liver functioning. Intravenous injections of Congo red in patients with liver disease, or in animals with experimentally damaged livers, were eliminated more slowly than in healthy subjects. The Congo red test is recommended for clinical use. **Relation of the reticulo-endothelial system to the functional liver test with Congo red.** *Ibid* 188–204.—In this and together with the preceding paper

substituted for 2 hydrogens on the phenyl group, toxicity is reduced. Introduction of the NH_2 group does not so markedly reduce toxicity as it prolongs the induction period, apparently a period of time when the substance is penetrating the cell. Organisms desiccated in strong sugar soln. show this effect well. Bacteria taken during the lag period or late during the phase of death show greater susceptibility to the action of germicides than cultures in the late logarithmic or max. stationary phase.
W. G. Gaessler

The use of sodium taurocholate and crystal violet in the isolation of Bacterium tumefaciens Sm. & Towne. M. K. Patel. Ia. State Coll., Ames. *Proc. Iowa Acad. Sci.* **34,** 88–89(1927).—Melt 15 g. of agar in 1000 cc. of distd. H_2O. Add 3 g. of sodium taurocholate, 10 g. of peptone and boil until well mixed. Add 20 g. of dextrose and adjust to p_H 7.0. Add 2 cc. of 1–1000 (aq.) crystal violet and make up to 1000 cc. Filter through cotton until clear. Tube and sterilize in an autoclave for 15 min. at 15 lb. pressure.
W. G. Gaessler

A substitute for beerwort as a yeast medium in the bacteriology laboratory. John C. Weldin. Iowa State Coll, Ames. *Proc. Iowa Acad. Sci.* **34,** 89–90(1927).—A liquid medium in which yeasts produce abundant gas is: malt ext. (Difco) 15 g., K_2HPO_4 1 g., NH_4Cl 1 g., distd. H_2O 1000 cc. The medium is adjusted with citric acid to p_H 5.4–5.6. A solid medium on which yeasts grow vigorously is: malt ext. (Difco) 15 g., K_2HPO_4 3 g., NH_4Cl 1 g., agar 20 g. (amt. of agar, however, optional). The medium is adjusted with citric acid to p_H 5.4–5.6.
W. G. Gaessler

Relative costs of home-made and dehydrated nutrient agar. Max Levine. Ia. State Coll., Ames. *Proc. Iowa Acad. Sci.* **34,** 91(1927).—Batches of 1, 4, and 7 l. of nutrient agar were prepd from the ingredients according to standard methods, and the costs compared with those of similar batches made from com. dehydrated nutrient agar. The costs of ingredients, labor, and loss due to filtration were the only items considered. It was found uneconomical to prep. nutrient agar from its constituents in batches of less than 2.5 l. with labor at 40c an hr. (about $80.00 per month). The higher the cost of labor, the larger the batch of agar that would have to be made to have costs compare favorably with the use of commercially dehydrated nutrient agar.
W. G. Gaessler

Influence of bile and brilliant green on rate of growth of colon bacilli. Harold W. Coles and Max Levine. Ia. State Coll., Ames. *Proc. Iowa Acad. Sci.* **34,** 92 (1927).—Evapd. bile may inhibit or stimulate growth of colon bacilli depending on concn. of bile, reaction of the medium, and the strain of organism employed. With all samples of bile employed a concn. of 2.0% accelerated growth whereas 5.0% was inhibitory in acid media (about p_H 6.0), and stimulating in alk media (p_H 7.3–7.8). With 2.0% dried bile concns. of more than 1–50,000 brilliant green distinctly retarded growth, and with 5.0% evapd. bile concns. of 1–20,000 or less of the dye were not considered inhibitory.
W. G. Gaessler

Some observations on the germicidal efficiencies of alkalies. Max Levine, J. H. Buchanan, Grace Lease and E. E. Peterson. Ia. State Coll., Ames. *Proc. Iowa Acad. Sci.* **34,** 93(1927).—For a given alkali, the germicidal efficiency increases with decreasing H-ion concn. but the H-ion concn. is not suitable as an index of the germicidal powers of different alkalies. The addn. of various salts to NaOH increased the germicidal effects of the alkali.
W. G. Gaessler

Some errors in the use of physicochemical concepts in physiology of bacteria. R. E. Buchanan. Ia. State Coll., Ames. *Proc. Iowa Acad. Sci.* **34,** 94(1927).—(1) A confusion of terms leads to the fallacious conclusion that the chance distribution of resistances of microörganisms to lethal agencies justified the expectation that the survivors' curve should conform to the monomol. reaction curve. (2) Not only rates of growth and death of an organism depend upon phys. and chem. environment, but the position of the min., the optimum, and max. growth temps. as well. (3) There exists more or less confusion with reference to the application of the van't Hoff-Arrhenius equation and the evaluation of a temp const. (4) There have been fallacious interpretations of survivors' curves in terms of conformity to those typical of monomol., bimol. and trimol. chem. reactions.
W. G. Gaessler

The bactericidal action of the common phenols and some of their derivatives on Bacillus pestis. J. F. Cains. *Indian J. Med. Research* **15,** 117–34(1927); *Bull. Hyg.* **3,** 496(1928).—The bactericidal action of the following substances was studied (1) phenol, (2) phenol derivs., (3) phthaleins, (4) derivs. of fluorescein. Table of results and discussion of chem. constitution are included.
George R. Greenbank

The bactericidal action of some compounds of mercury on Bacillus pestis. J. F. Cains, S. A. Kamal and B. P. Naidu. *Indian J. Med. Research* **15,** 327–33(1927);

Bull. Hyg. **3,** 497(1928).—The mercurial compds. studied were phenols, red and blue trypan and acid fuchsin. *p*-Chloromercuriphenol was found to be inhibitory in dilns. of 1 to 320,000. The dyestuff derivs. had little influence. GEORGE R. GREENBANK

Studies on lactic acid streptococcus. KARL J. DEMETER. *Milchwirtschaft. Forsch.* **5,** 505–31(1928).—A study was made of the effect of temp., acidity, fat content of milk, chem. stimulants and physiol. nutrition, upon the coagulation and reduction potential of milk cultures, by this group of organisms. GEORGE R. GREENBANK

A theory of the formation of zymase in the living cell. EGERTON C. GREY. Univ. Cambridge. *Proc. Roy. Soc.* (London) **B103,** 302–11(1928).—*B. coli communis* acts upon carbohydrates to produce either lactic acid fermentation or a modified alc. fermentation; a recent aerobic environment is prerequisite for the latter fermentation. Zymase is the surviving part of the respiratory mechanism; it is not readily formed under aerobic conditions, but is produced by a distortion of the normal respiratory mechanism which decreases as the enzyme is secreted. JOSEPH S. HEPBURN

Enzymes of Bacillus coli communis. VI. The alternative modes by which B. coli communis may bring about the anaerobic decomposition of glucose. EGERTON C. GREY. Univ. Cambridge. *Proc. Roy. Soc.* (London) **B103,** 312–20(1928).—Under anaerobic conditions, *B. coli communis* may produce (1) a combination of cleavage, oxidation and reduction, analogous to alc. fermentation by yeast, with the fundamental difference that HCOOH is formed instead of CO_2, or (2) a combination of cleavage and mol. stabilization. The latter is essentially a lactic acid fermentation; it supplies less energy to the cell, but is simpler and apparently less influenced by the reaction of the medium; hence it occurs when the vitality of the organism is low as the result of age, prolonged absence of O_2, and accumulation of toxic products. JOSEPH S. HEPBURN

The effect of arsenious acid on respiration and fermentation. II. KURT DRESEL. *Biochem. Z.* **192,** 351–7(1928); cf. *C. A.* **22,** 2618.—Glucose has a certain protective effect against the restrictive action of As_2O_3 on the respiration and fermentation by yeast. In the presence of KH_2PO_4 1% glucose caused a greater restriction by As_2O_3 than occurred in the absence of glucose. Sulfates of Fe, Mn, Co, Cu, Zn and Ni decrease respiration and fermentation in yeast, but when these have already been decreased by the action of 2×10^{-4} *M* As_2O_3, these salts produce little or no further change. E. H.

The resistance of Streptococcus fecalis to acid and alkaline media. A. W. DOWNIE AND J. CRUICKSHANK. *Brit. J. Exptl. Path.* **9,** 171–3(1928).—*Streptococcus fecalis* is resistant to exposure to very acid and very alk. media, and is easily obtained in pure culture by direct inoculation of feces into alk. broth p_H 11.0. H. F. H.

Cataphoresis experiments with the virus of vaccinia. S. R. DOUGLAS AND W. SMITH. *Brit. J. Exptl. Path.* **9,** 213–5(1928).—The virus of vaccinia carries a neg. elec. charge over a range p_H 5.5 to p_H 8.4. Cataphoresis at a H-ion concn. on the acid side of p_H 6.8 affords a means of sepg. the virus from tissue proteins. HARRIET F. HOLMES

The biochemical properties of diphtheria and so called pseudodiphtheria bacilli. W. H. DE WOLFF. *Nederland. Tijdschr. Hyg. Microbiol. Serol.* **3,** 38–70(1928).—The *Bacterium B of Hofmann-Wellendorf* decomposes *milk protein* energetically. The acid value decreases steadily after the 5th day. The formol titer rises, and the total N decreases, because of formation and loss of NH_3. The serum N increases and the curd N decreases with the age of the culture. The amino acid content rises. The protein decompn. is accompanied by a decrease in rotation, which must be attributed to the formation of *l*-rotatory decompn. products of protein, since lactose is not attacked. *Bacterium coli communis* and *Hofmann-Wellendorf A* do not attack milk proteins. *B. diphtheriae* and the *pseudodiphtheria bacilli* from the Lister and Krall collections practically do not attack milk protein. The former causes a slight increase in acidity; the latter decomposes *lactose* and curdles the milk. Several *diphtheroid bacteria* from the throat of chickens infected with bird or virulent human diphtheria attacked the protein slightly; the reaction varied from acid to neutral. MARY JACOBSEN

The silver-line system in ciliata. Further studies. BRUNO M. KLEIN. *Arch. Protistenk.* **62,** 177–260(1928); cf. *C. A.* **21,** 3210.—Staining ciliata with Ag salts outlines definite patterns of "argentophile" substance. FRANCES KRASNOW

A toxin-producing hemolytic streptococcus from septicemia. I. PILOT AND R. E. WESTLUND. *J. Infectious Diseases* **41,** 208–10(1927).—A strain of *Streptococcus hemolyticus* isolated from the blood of a patient with septicemia produced a toxin which resembles the toxin of streptococci of scarlet fever in skin reactions and in neutraliza-

tion tests with antitoxic serums. Agglutination reactions and absorption tests, however, failed to demonstrate a similar sp. relationship. Julian H. Lewis

Effect of surface tension on the growth of Escherichia coli. Wm. R. Albus. *J. Infectious Diseases* **41**, 211–4(1927).—When the growth of *E. coli* is expressed as a logarithmic curve it is found that pure Na ricinoleate reduces the no. of living organisms in the culture. The cell mortality does not take place until after the culture has passed through a normal logarithmic growth period. If the logs of the no. of cells are plotted against surface tension of the culture medium a straight line is produced which fact indicates that the mortality follows the surface tension of the medium and not the concn. of the soap as a depressant. Julian H. Lewis

Gas production by bacterial symbiosis with special reference to the influence of nitrogenous substances. Mitsuteru Ishikawa. Washington Univ. Med. School, St. Louis, Mo. *J. Infectious Diseases* 41, 238–56(1927).—The nonproteolytic, gas-forming bacteria alone cannot produce noticeable amts. of gas from carbohydrates and salts of formic acid in media contg. only complex nitrogenous substances as milk, ascitic fluid, casein, nutrose and gelatin, but gas is generated intensively by these bacteria in such media if they are grown in assocn. with the proteolytic bacteria, and demonstrable amts. of gas are formed if simple forms of nitrogenous substances—the digestion products of proteins, peptone, amino acids and NH_4 salts—are added to such media. The formation of gas from carbohydrates by the associative cultures of 2 kinds of saccharolytic bacteria, an acid-producing organism and a gas-forming bacterium, does not take place markedly in ascitic fluid, casein, nutrose and gelatin media, except under the following conditions: When a proteolytic organism is cultivated in assocn. with the 2 saccharolytic bacteria; or when simple nitrogenous substances—peptone, amino acids or ammonium salts—are added to the medium. The role played by the proteolytic bacteria in these cases is that they pave the way for the fermentative activity of the saccharolytic bacteria by breaking down the proteins of the media into simple forms of nitrogenous substances which are apparently necessary for the formation of gas. It is probable that such simple nitrogenous substances accelerate the activity or the production of the sp. enzyme, formiase, which is thought to be responsible for the production of gas. Many of the NH_4 salts, as the sole source of N, satisfy the bacterial requirements for growth and fermentative activity, but NH_4 benzoate and NH_4 salicylate are unsuitable for either of these requirements. J. H. L.

The growth of hemophilic bacilli with certain iron salts. Janet M. Bourn. Michael Reese Hospital, Nelson Morris Institute and Univ. of Chicago, Chicago, Ill. *J. Infectious Diseases* 41, 294–303(1927).—Certain hemophilic bacilli can be cultivated through successive transfers in veal infusion broth to which Na aquopentacyanoferroate has been added, whereas, homologous bacilli do not survive beyond the primary culture when the Fe salt is not present. In a chemically defined synthetic medium which contains the Fe salt, these hemophilic bacilli gave evidence of growth in the primary culture when an unwashed bacterial inoculum has been used, but this does not serve to initiate growth in a secondary culture. The evidence suggests that pentacyano Fe salts do not function independently as the X factor in bacterial nutrition, but that the biocatalytic activity observed is the result of an interaction between the inorg. Fe salt and some thermostable tissue deriv. from an animal source. J. H. L.

The optochin fastness of pneumococci. Claus W. Jungeblut. New York State Dept. of Health. *J. Infectious Diseases* 41, 345–54(1927).—Strains of type 1 pneumococci which had become adapted to optochin did not show cellular changes differing from the normal, nor was there any difference in the p_H of the cultures of the 2 types. Normal strains of pneumococci grown in the sterile filtrates of adapted strains may occasionally acquire an increased tolerance to optochin. This acquired adaptation does not seem to be assocd. with biologic changes in the organisms but with some unknown substance present in the active filtrates. Julian H. Lewis

Effect of Cl. sporogenes on toxin production by Cl. botulinum. E. Wagner Sommer and Kathryn Glunz. Univ. of Calif. Med. School, San Francisco. *J. Infectious Diseases* 41, 442–7(1927).—Spore suspensions of *Cl. botulinum* and *Cl. sporogenes* inoculated in varying relative amts. into meat, spinach and asparagus media, which are incubated for 10 days and tested for the presence of toxin, reveal botulinum toxin in all the meat cultures in which *Cl. botulinum* is present, irrespective of the no. of sporogenes. The inoculation of an equal or greater no. of *Cl. botulinum* with sporogenes is usually necessary for toxin production in spinach. In asparagus, a poorer toxin medium, a more deleterious influence of sporogenes on botulinum toxin was noted. In meat, spinach and asparagus media increasing nos. of sporogenes gradually diminish the strength of the toxin. Julian H. Lewis

The specificity of scarlet fever streptococci. S. I. Zlatogorov and V. S. Derkach. Bacteriol. Inst., Kharkov, Ukrainia, U. S. S. R. *J. Infectious Diseases* **42,** 56–65 (1928).—Streptococci derived from sources other than scarlet fever produce toxic substances (toxins). These substances cause a skin reaction of the Dick type under the same conditions as the toxins of scarlatinal streptococci. Substances producing the phenomenon of extinction (blanching test of Schultz-Charlton) may be obtained by immunization with scarlatinal as well as nonscarlatinal streptococci. A positive Dick reaction may be obtained during the period of scarlet fever complications with scarlatinal as well as nonscarlatinal streptococci. This is supposed to be a case of reaction to the unsp. bacterial proteins. Scarlatinal serums give the reaction of flocculation (pptn.) with toxins of streptococci derived from various pathogenic sources. Neither the toxin production nor the Schultz-Charlton test confirms the specificity of scarlet fever streptococci. Julian H. Lewis

Studies on the metabolism of the abortus-melitensis group. II. Further observations on nitrogen metabolism. James G. McAlpine and Charles A. Slanetz. Storrs Agr. Expt. Station., Conn. *J. Infectious Diseases* **42,** 66–71(1928).—*B. abortus* of bovine origin utilizes very little or no glucose in its metabolic activity. On the other hand *B. abortus* of porcine and human origin and *B. melitensis* consumed from 4 to 18% of this carbohydrate for growth energy. By this difference in sugar metabolism *B. abortus* bovine can be differentiated from *B. abortus* porcine and human, and from *B. melitensis* by the different amts. of the various N fractions present in the culture media over a 14-day incubation period. This difference is apparent only in glucose-contg. media. CO_2, 10%, stimulates the growth of *B. abortus* bovine, even though the strains may have become accustomed to aerophilic conditions, but it partially inhibits the multiplication of *B. abortus* porcine and human, and *B. melitensis.* This inhibition may be due to slight changes in H-ion concn. caused by the CO_2 and perhaps partly to a decrease in O supply in the closed, as compared with the open, culture system. **III. Glucose utilization.** *Ibid* 73–8.—Quant. sugar detns. made by the Somogyi and Benedict methods, and p_H detns. (colorimetric), when Fairchild's peptone is employed in the medium show that the *B. abortus-melitensis* group may be split into 2 main parts. The first of these includes all strains which are unable to utilize more than 2% of glucose. The 2nd group includes those which utilize 5–20% of the carbohydrate and is made up of *B. abortus* of human and porcine origin, and *B. melitensis.* These results were consistent with a large no. of strains, barring 1 exception. This was a bovine strain which showed 8–10% utilization. It is not unlikely that in some instances cows become infected with the porcine strain. All of the human strains were apparently more closely related to the porcine strains than they were to those of bovine origin. Julian H. Lewis

The successful cultivation of the gonococcus on blood-agar plates. Russell D. Herrold. John McCormick Inst. for Infectious Diseases. *J. Infectious Diseases* **42,** 79–83(1928).—Blood is more valuable as an enrichment for nutrient solid media for isolating gonococci if 0.75% to 1% agar is used. The value of this medium is further enhanced by the use of phosphate instead of NaCl and the addition of blood (10–15%) to the agar at 65° followed by gradual cooling to 45° before pouring into plates or slants. Nutrient solid media thus prepd. have proved valuable in isolating gonococci from both chronic and acute infections. Julian H. Lewis

Quantitative estimation of casein hydrolysis by Clostridium botulinum. Gail M. Dack and Willard L. Wood. Univ. of Chicago. *J. Infectious Diseases* **42,** 172–5 (1928).—*Cl. botulinum* will grow and produce toxin in a medium contg. casein and peptone. The peptone is first utilized for growth; after a secondary incubation period the casein is broken down and used in further growth and toxin production. The curve for the toxin titer shows a relationship to casein hydrolysis as indicated by the total N curve. Julian H. Lewis

The attenuation and toxin production of the diphtheria bacillus. 1. Attenuation of the diphtheria bacillus. 2. Synthetic media. 3. Factors affecting growth and toxin production. Augustus Wadsworth and Mary W. Wheeler. N. Y. State Dept. of Health, Albany. *J. Infectious Diseases* **42,** 179–208(1928).—In the synthetic medium of Uschinsky, attenuation of the diphtheria bacillus was obtained in 1 instance with complete loss of virulence and toxin production. Neither virulence nor toxin production could be restored by cultivation in media or animal passage. In a synthetic peptone medium free from meat infusion, containing only the chlorides, sulfate and phosphates of Na, Ca and Mg, with dextrose as a source of energy and peptone as a source of N, the diphtheria bacillus not only grew but produced toxin. A potent toxin, however, was obtained only when in the prepn. of this medium the Ca and phos-

phate ions were heated together in the presence of peptone. The calcium ions could be replaced by equiv. amts. of Ba or Sr but not by Mg or Mn. The addition of a small amt. of colloidal Ca phosphate to an infusion-free peptone medium, which, without the colloidal Ca-phosphate, was not favorable for toxin production, increased toxin production from 10- to 100-fold. The pptn. of Ca, however, from toxin after it had once been produced by the diphtheria bacillus, did not alter the potency of that toxin.

JULIAN H. LEWIS

The mechanism of toxin production by Clostridium botulinum. GAIL M. DACK AND WILLARD L. WOOD. Univ. of Chicago. *J. Infectious Diseases* **42,** 213-7(1928).—Supernatant fluid from a 48-hr. beef heart culture of *Cl. botulinum,* type A, when added to thymolized beef heart, egg white, and casein media, on incubation, showed the following changes: the toxin was much weakened but not completely destroyed; there was evidence of proteolytic activity. Similar results were obtained when the cell suspensions were added to thymolized beef heart medium. The toxin was completely destroyed in the thymolized cell suspensions and supernatant fluid in the absence of added protein media. JULIAN H. LEWIS

A new differential medium for the paratyphoid group. EDWIN O. JORDAN AND PAUL H. HARMON. Univ. of Chicago. *J. Infectious Diseases* **42,** 238-41(1928).—The compn. of the new medium is: agar 20 g., distd. H_2O 1000 cc., alc. soln. of phenol red (0.2%) 12 cc., Difco peptone 10 g., Na K tartrate 10 g., NaCl 5 g. On stab inoculation of this medium in tubes organisms of the *B. schottmülleri* group produce an alk. reaction (red) and those of the *B. aertrycke* group produce acid (yellow). The differentiation is definite and the ingredients of the medium are simple and inexpensive. (Cf. Brown, Duncan and Henry, *C. A.* 19, 840.) JULIAN H. LEWIS

The Twort-d'Herelle phenomenon. A critical review and presentation of a new conception (homogamic theory) of bacteriophage action. PHILIP HADLEY. Univ. of Michigan. *J. Infectious Diseases* 42, 265-434(1928). JULIAN H. LEWIS

Effect of reduced oxygen tensions on the growth of Clostridium botulinum (type A) in veal infusion broth. GAIL M. DACK AND MEREDITH BAUMGARTNER. Univ. of Chicago. *J. Infectious Diseases* 42, 491-4(1928).—*Cl. botulinum,* type A, was grown in veal infusion broth under reduced O pressures. No growth was obtained where the O pressure was greater than 1.3 cm. As the O pressures increased from 0.1 cm. to 1.3 cm. the time of growth became more irregular. JULIAN H. LEWIS

Gas production from commercial peptones by Bacillus aerogenes and Bacillus coli. E. LEE TREECE. Univ. of Kansas. *J. Infectious Diseases* **42,** 495-500(1928).—Gas was produced from 2 of the 4 com. peptones tested by *B. aerogenes* and *B. coli,* both in a liquid medium under vaseline and in a peptone medium solidified with agar or gelatin. The gases produced by *B. coli* and *B. aerogenes* were collected, measured and analyzed. The gas ratio (CO_2/H_2) for *B. aerogenes* averaged 8.5, varying from 5.7 to 12.8. The gas ratio for *B. coli* was infinitely higher; the value could not be detd. since the amt. of H_2 produced was too small to be measured and analyzed. This wide variation indicates fundamental differences in the modes by which *B. coli* and *B. aerogenes* break down the gas-producing substance of commercial peptone. The source of the gas seems not to be in the carbohydrate radicals of the peptone. J. H. L.

The sanitary significance of lactose-fermenting bacteria not belonging to the Bacillus coli group. 1. Groups reported in the literature and isolated from water in Chicago. FRANK E. GREER. Dept. of Health, Chicago. *J. Infectious Diseases* **42,** 501-13(1928).—2. **Number of lactose-fermenting organisms found in Chicago sewage and Chicago water supply.** *Ibid* 514-24. 3. **Bacterial associations in cultures containing lactose-fermenting bacteria.** FRANK E. GREER AND FLORENCE V. NYHAN. *Ibid* 525-36. 4. **Pathogenicity.** FRANK E. GREER, FRED O. TONNEY AND FLORENCE V. NYHAN. *Ibid* 537-44. 5. **Factors influencing the survival of microörganisms in water.** FRANK E. GREER. *Ibid* 545-50. 6. **Sanitary considerations.** *Ibid* 551-5. 7. **Media and methods.** FRANK E. GREER, R. E. NOBLE, FLORENCE V. NYHAN AND A. E. O'NEIL. *Ibid* 556-67. 8. **Conclusions.** FRANK E. GREER AND R. E. NOBLE. *Ibid* 568-74.—It is pointed out in this series of articles that other organisms besides *B. coli* occur in H_2O which ferment lactose. Some of these should be considered in judging the sanitary quality of drinking H_2O. Media that have been developed for high selectivity for *B. coli* actually, in many cases, inhibit the growth of this organism or allow the development of extraneous forms which may confuse or render cultural tests worthless as an index for the colon organism. The best combination of media and methods so far developed for routine practice include lactose broth for the presumptive test, eosin-methylene blue for the confirmatory test, and lactose broth and agar slants for the completed test.

JULIAN H. LEWIS

Bactericidal properties of the acyl and alkyl derivatives of resorcinol. BETTYLEE HAMPIL. Johns Hopkins Univ., Baltimore. *J. Infectious Diseases* **43**, 25–40(1928).—The bactericidal properties of the alkylresorcinols and their intermediate ketones were studied. The higher alkyl derivs. of resorcinol in comparison with phenol are less effective as bactericides against *B. typhosus* grown in Witte peptone broth than against the same organisms grown in Difco peptone broth. These 2 peptones differ in their nitrogenous content and in other factors not detd. In the presence of org. material at 37° the alkylresorcinols progressively lose a portion of their bactericidal activity. Beginning with *n*-butylresorcinol, the percentage of inhibitory effect increases until at *n*-heptyl- and *n*-octylresorcinol there is a total loss of disinfecting power. An elevation of temp. from 20° to 37° increases the bactericidal properties of each member of the alkyl series from the *n*-propyl to the *n*-octyl derivs. A further elevation from 37° to 45° renders nonyl- and decylresorcinol also potent as bactericides in aq. soln. Because of the increased soly. of the alkyl resorcinols in alkali, the addn. of 1% Na_2CO_3 to these compds. causes a pronounced rise in microbicidal action beyond the hexyl deriv. both in the presence and absence of org. material. The disinfecting properties of the alkyl derivs. *in vitro* depend to a great extent upon their H_2O soly. Each member of the acyl series of derivs. of resorcinol is increased in bactericidal power by an elevation of temp. from 20° to 37° from the *n*-butyryl to the *n*-hexylyl compd. These derivs. are practically ineffective as bactericides at 37° in a standard org. mixt. *n*-Hexyl-, *n*-heptyl- and *n*-octylresorcinol appear to possess a specificity in disinfection action against the vegetative forms of Gram-positive organisms at 37°. In high dilns. of the compd., the alkylresorcinols show a wide zone in which their activity against bacteria is fluctuating and uncertain. This zone is progressively increased as the alkyl chain is extended. JULIAN H. LEWIS

Influence of carbohydrates on bacterial decomposition of urea. MITSUTERU ISHIKAWA. Washington Univ. School of Med., St. Louis, and Northwestern Univ. Med. School, Chicago. *J. Infectious Diseases* **43**, 67–80(1928).—*B. ammoniogenes B. aerogenes, B. morgani, B. proteus vulgarus* and *Staphylococcus aureus* actively decompose urea in culture media; the washed cells of these bacteria also possess a definite urea-splitting activity. The presence of a utilizable carbohydrate accelerates the disintegration of urea by these bacteria, cultured and washed. Na formate added to the culture medium does not exert any increasing effect. Thymol has an inhibitory influence on the liberation of NH_3 from urea, by cultured or washed organisms, in the presence or absence of glucose. The symbiosis of urea-splitting organisms with a non-urea-splitting bacterium, in a medium containing a carbohydrate fermentable by the latter organisms but not by the former, increases the generation of NH_3, in comparison with the single culture of the urea-splitting organism. J. H. L.

Behavior of Brucella melitensis and abortus toward gentian violet. I. FOREST HUDDLESON AND ELIZABETH ABELL. Michigan State College, Lansing. *J. Infectious Diseases* **43**, 81–9(1928).—Varieties, and strains within a variety, of the genus *Brucella* exhibit a difference in sensitiveness to gentian violet in a medium, expressed in degree of growth. The growth of strains of the *Br. melitensis* and *Br. paramelitensis* variety is not inhibited on a medium by the presence of gentian violet in dilns. of 1:100,000 and 1.250,000 A few of the strains are slightly inhibited by the presence of a 1:50,000 diln. of the dye. Strains of the *Br. abortus* variety may be divided into 2 groups as regards their ability to grow on a medium in which gentian violet is present, namely, those which are markedly inhibited and those which fail to grow in the presence of 1:50,000 and 1:100,000 diln. of the dye. The latter group contains one bovine strain, several human strains and all procine strains in the possession of the writers. The difference in dye sensitivity may prove to be a means of distinguishing strains of the abortus variety not otherwise distinguishable. JULIAN H. LEWIS

The action of phenol and formol on aerobic and anaerobic organisms. JOSEPH P. SCOTT. Kansas State Agr. Expt. Sta. *J. Infectious Diseases* **43**, 90–2(1928).—Phenol in strengths up to 5% acts very slowly on anaerobic organisms, while CHOH in dilns. of 0.5 to 0.75% sterilizes anaerobic cultures rapidly. The greater susceptibility of aerobic spore-forming organisms to these disinfectants makes it possible to eliminate aerobic contaminations from anaerobic cultures by the use of 0.5% phenol or CHOH. JULIAN H. LEWIS

Surface tension in relation to bacterial growth with special reference to Lactobacillus acidophilus and Lactobacillus bulgaricus. ALEXANDER A. DAY AND WM. M. GIBBS. Northwestern Univ. Med. School, Chicago. *J. Infectious Diseases* **43**, 97–107(1928).—Coconut soap, palmitic soap, olive soap Na ricinoleate, Na oleate and Na taurocholate had no effect on the growth of *L. acidophilus* and *L. bulgaricus* which

could be attributed to the depressant action of these substances on surface tension. Na ricinoleate exerted a toxic action toward both *L. acidophilus* and *L. bulgaricus*, but this action could not be employed as a means of identifying the 2 organisms. The fermentation of maltose, sucrose and levulose does not offer a means of differentiating *L. acidophilus* and *L. bulgaricus*. JULIAN H. LEWIS

Bacterial adaptation to acriflavine. VICTOR BURKE, CATHERINE ULRICH AND DON HENDRIE. State College of Washington. *J. Infectious Diseases* **43**, 126–30(1928).—*Staphylococcus albus* shows increased tolerance for the dye after 6–8-hrs. exposure. This adaptation is temporary and disappears when the organism is grown on dye-free agar. Delayed growth in the presence of acriflavine is due in part to the process of adaptation of the organism. The increased tolerance in partially sp. *Staphylococcus* can be sepd. into 2 strains which differ in their ability to tolerate neutral acriflavine. JULIAN H. LEWIS

Choice of antiseptic dye in mixed infections. VICTOR BURKE, M. P. JESSUP AND SMITH PHILLIPS. State College of Washington. *J. Infectious Diseases* **43**, 131–6 (1928).—Gentian violet is more bactericidal than neutral acriflavine for both the Gram-positive and the Gram-negative organisms commonly found in wounds. Blood reduced the bactericidal action of both dyes. No advantage is gained by mixing the 2 dyes. The dye most effective against the most resistant organism in the wound to be treated should be used. Since bacteria acquire sp. dye tolerance in a few hrs. rotation of dyes in the treatment of infections may be beneficial. The bactericidal strength of neutral acriflavine varies with the manufacturer. Different samples from the same manufacturer are nearly uniform in bactericidal action. JULIAN H. LEWIS

The bioscopic reduction test as a means of study of bacterial life processes. The dependence of rest-reduction and catalase content of bacteria on certain factors. OTTO KIRCHNER. *Z. Immunitäts.* 52, 108–24(1927).—The quant. estn. of the catalase content of *Staphylococcus aureus*, *B. coli* and *B. pyocyaneus*, grown in sugar, sugar-free, solid and liquid media, shows that the catalase content of the culture media fluctuates very greatly. Factors that influence the catalase content markedly are the changes of reaction which lower the catalase content when to the acid side and the supply of O_2, the activity being low in anaerobic conditions and high in aerobic. After 10 days growth there is always a constant increase in catalase. In order to obtain bacteria with the lowest possible "rest-reduction," which is necessary for the bioscopic reduction test, it is necessary to employ fluid media without sugar. The relation between H_2O_2 formation and catalase content on one hand and methylene blue reduction on the other is discussed. JULIAN H. LEWIS

Pancreas and bacteriophage action. E. KLEINEBERGER. Univ. Frankfurt. *Z. Immunitäts.* **56**, 32–45(1928).—Bacteriophage is never present in normal sterile organs, but it is easily obtained from unsterile pancreas and thymus of stockyard animals. In more than 50% of hogs killed in the stockyards bacteriophage is found in the small intestines and to a less extent in other parts of the intestines. The occurrence of bacteriophage in other organs is due to a contamination from the intestinal tract. Ground sterile pancreas introduced into bouillon containing bacteriophage causes a marked increase of the latter. Sterile thymus and boiled pancreas have the same action but to a less extent. This effect of pancreas is not due to its enzymes. The bacteria from unsterile stockyard pancreas do not form bacteriophage. J. H. L.

Catalase formation by Bacillus coli and its differential value. O. FERNÁNDEZ AND T. GARMÉNDIA. *Z. Hyg. Infektionskrankh.* **108**, 329–35(1928).—The production of catalase by *B. coli* increases or decreases according to the nature of the nutrient medium. The variability is such that a classification of strains on the basis of catalase production is at present impossible. E. R. LONG

The influence of carbon monoxide and of nitric oxide on respiration and fermentation. OTTO WARBURG. *Biochem. Z.* **189**, 354–80(1927).—The effect of CO on respiration of yeast depends upon the ratio CO/O_2 in the gas mixt. Large effects were observed in liver, chorion and retina; smaller effects were noticed in embryos and sarcomas of rats while no influence was observed in the case of chicken sarcoma. It is concluded that the respiratory enzyme reacts with CO, the combination being broken up by light. The respiratory enzyme is related to but is not identical with hemoglobin, while it is not related at all to the cytochrome present very generally in cells. CO does not affect fermentation, either alc. or lactic acid fermentation. NO inhibits the fermentation metabolism of tumor tissue 50–60%. After displacing the NO by N_2 gas, the metabolism of the tumor tissue returns to normal. Alc. fermentation of yeast at 37° is completely suppressed by NO and is not reactivated after the removal of the NO. However, the higher the temp. at which the yeast is reacting with NO the less

reversible does the resulting inhibition of the alc. fermentation become. On the other hand, the NO combined with the enzyme is more easily removed the higher the temp. so that there must be 2 distinct reactions with NO, a reversible and irreversible, the latter killing the cells. It is the latter reaction which is obviously absent in tumor tissue. S. MORGULIS

Nitrogen distribution in the paunch of ruminants during feeding and starvation and its relationship to paunch infusoria. ERNEST MANGOLD AND CONSTANZE SCHMITT-KRAHMER. Tier physiol. Inst. Landw. Hochschule, Berlin. *Biochem. Z.* **191**, 411–22 (1928).—Bacterial N constitutes 10% of the total N of the paunch contents of normally fed sheep. No evidence was found that the paunch infusoria contribute an appreciable amt. to the total N content. The total N of the paunch contents in normally nourished sheep is 0.2 to 0.3%, but varies with the consistency of the contents, the nature of the food and diminishes very rapidly in fasting. On the seventh fasting day it falls as low as 0.05%. No formol titratable N could be demonstrated but NH_3 was present. S. MORGULIS

Chemical components of the spores of Aspergillus oryzae. MIDZUHO SUMI. *Biochem. Z.* **195**, 161–74(1928).—The spores of *A. oryzae* contain only traces of sol. reducing sugar or pentosan but a large amt. of mannitol; also glycogen is found in place of starch. There was much of P-contg. substances, such as lecithin, organically combined H_3PO_4 and inorg. phosphates. Of the org. bases, betaine was present in abundance, and also small amts. of stachydrin and histidine. Much chitin was isolated from the spore cell walls though it is not certain that other substances may not be present there. From the ether ext. a sterol was obtained of the compn. $C_{16}H_{28}O$, m. 160°. An ext. made with boiling water after the preliminary extn. with ether and alc. showed the presence of uric acid, as much as 0.6% of the air-dried original material. The following enzymes were demonstrated in the spores: sucrase, amylase, peptase, chymase, urease, glucosidase, peroxidase, nuclease, esterase, phytase and catalase. Lipase, tyrosinase, maltase, inulase, trehalase, desamidase and oxidase could not be definitely demonstrated. S. MORGULIS

The action of radium emanations on bacteria. H. v. SCHROETER. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104**, 205–10(1927).—Ra emanation produces hypertrophy of bacterial cells, the nature of which varies in type and degree with different species. JOHN T. MYERS

Bacterium coli as an alkali-forming organism. S. GOLIKOVA. Univ. Moskau. *Centr. Bakt. Parasitenk. I Abt. Orig.* **108**, 213–9(1928); cf. *Centr. Bakt. Parasitenk. I Abt. Orig.* 96, 95(1925).—White islands sometimes appear on Endo plates which had been reddened by *B. coli* in the presence of a mixed flora as when feces have been cultured. A possible explanation is the presence of an alkali proenzyme which becomes active under the influence of alkali. This enzyme produces volatile alkali; hence the phenomenon may occur at a distance as well as by continuity. Decolorized areas do not regain color when the products of alkali formers are removed from the atm. The areas induced at a distance can induce secondary white areas. The phenomenon is not dependent on living cultures. JOHN T. MYERS

Culturing the tubercle bacillus. STEFANIA LICHTENSTEIN. Univ. Leipzig. *Centr. Bakt. Parasitenk. I Abt. Orig.* **108**, 239–41(1928).—The following method gives a very high % of positive cultures. Mix 1 or 2 cc. of sputum or other material with 10 cc. of 10% HCl, shake for 10 min. and then centrifuge for 10 min. Inoculate the sediment on the medium of Petragnani prepd. as follows. Mix 150 cc. of milk, 6 g. of potato meal and a piece of potato the size of an egg, chopped finely. Place in a boiling water bath and shake for 10 min., then let stand in the bath for 1 hr. Cool to 50° and add 4 whole eggs, 1 egg yolk, 12 cc. of glycerol and 10 cc. of 2% malachite green. Shake vigorously and filter through gauze. Tube and sterilize at 80° for 20 min. on 3 consecutive days. JOHN T. MYERS

The physical chemistry of the d'Herelle phenomenon. K. v. ANGERER. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104**, 261–2(1927).—Somoluchowski developed a formula which expressed the rate of reaction between bacteriophage and bacteria and predicted a slow rate. A. attempted to confirm this experimentally by mixing bacteriophage and bacterial suspension and plating after varying periods of contact. Contrary to expectations the period of contact had no relation to the no. of lysed areas on the plates. Dead bacteria could unite with bacteriophage, thus fixing it. In 15 min., 90 to 95% of the bacteriophage was bound. After 1 hour the union was practically complete. The bacteriophage can diffuse through the agar. The reaction follows the law of adsorption, the exponent $1/N$ having a value of 0.75–0.80. One can thus calc. the amt. of free and bound bacteriophage. The bacteriophage is neither a single

organism nor a single ferment but a group of ferments. If only a few lytic doses are present, they are concd. in the most sensitive bacterial cells. The diffusion of bacteriophage can be best followed by cinematographic records. JOHN T. MYERS

The theory of growth inhibition of bacteria by hydrocyanic acid. E. LOEFFLER AND R. RIGLER. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104,** 265-6(1927); cf. *C. A.* **21,** 2915.—The poisonous effect of HCN on the bacterial cell is due largely to a non-sp. interference with cystine metabolism, rather than to a change in the oxidation-reduction potential. JOHN T. MYERS

The influence of oxone (oxidases and peroxidases) of leucocytes and of bone marrow on bacteria in vivo and in vitro. A. NEUMANN. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104,** 266–9(1927).—Oxone consists of the oxidases and peroxidases in exts. of bone marrow and leucocytes, which are free from hemoglobin. In the blood they are found chiefly in the cytoplasmic granules of the neutrophiles and eosinophiles. *In vitro* they favor the growth of bacteria. When injected into white mice in small optimum doses along with *B. typhi murium,* they decrease lethal power, but with larger doses virulence is increased. JOHN T. MYERS

The ectoplasm of yeast cells. The chemical constitution of the cell membranes and of substance. JOSEPH SCHUMACHER. *Centr. Bakt. Parasitenk. I Abt. Orig.* **108,** 193–207(1928).—There are 3 parts to the yeast cell: the Gram-positive lipoid contg. endoplasm, the Gram-negative cell membrane which contains a reducing substance, and the weakly Gram-positive, lipoid-contg. cement substance. The stained endoplasm can be removed by repeated washing and centrifugation with distd. water. The membrane of the vegetative yeast cell contains no lipoid or lipoid-protein complex. It consists of a S, Fe and glucosamine contg. phosphoglycoprotein. The cement substance contains a N- and P-contg. lipoid which is sol. only in hot alc. and which is apparently identical with the lipoid of the myelin sheath of nerves The cell membrane of yeast spores on the contrary contains a lipoid-protein complex. J. T. M.

Staphylococcus enzymes. HANS GROSS. Inst. exptl. Therapie, "Emil v. Behring," Marburg L. *Centr. Bakt. Parasitenk. I Abt. Orig.* **108,** 241-5(1928).- Staphylococcus filtrates contain an enzyme which coagulates citrated blood, but proteolytic enzymes were not found. JOHN T. MYERS

The action of dyes on bacteria. III. The action of mixtures of dyes. FR. SARTORIUS. Westfal Wilhelms-Univ. zu Munster. *Centr. Bakt. Parasitenk. I Abt. Orig.* **108,** 313–26(1928); cf. *C. A.* **22,** 3427.—In general, mixts. of dyes were no more active than their pure components, but the effects were sometimes additive. The most active dyes belonged to the triphenylmethane group. In general, the Gram-positive staphylococcus was more easily killed by dyes than was the Gram-negative colon bacillus. The addn. of $CuSO_4$ increased the lethal power of dyes while $CdSO_4$ decreased it. Colloidal Au, Ag and Cu solns., which in themselves are not bactericidal, markedly increase the action of dyes. JOHN T. MYERS

The value of disinfection tests. K. FISCHER. *Centr. Bakt. Parasitenk. I Abt. Orig.* **108,** 327–40(1928).—If it is desired to det. the bactericidal action of a substance, a method is necessary which gives the time required to kill all cells at a given concn. If inhibitory action is the point in question, a method must be used which employs bacterial counts. JOHN T. MYERS

The influence of putrefactive gases on Bacillus anthracis. PETRO ANDRYEVSKII. Urkanian Univ., Prague. *J. Bact.* **16,** 151–5(1928).—A bottle was half filled with cattle meat and parts of organs, with the addn. of a sufficient amt. of water and closed with a rubber stopper perforated with a bent glass tube. After putrefaction had set in the free end of the glass tube was sterilized in the flame and pushed to the bottom of a broth culture of anthrax bacilli. When the gases had bubbled through for 16 to 24 hours, all of the bacilli were dead. The principal putrefactive gases formed were: CO_2, H, CH_4, NH_3 and H_2S. These were tested separately, and H_2S was found to have the most destructive effect both on vegetative cells and spores. Cadavers of animals infected with anthrax can be treated with H_2S and the organisms so decreased in numbers that danger of spread of the disease is greatly reduced. JOHN T. MYERS

The precipitation of magnesium ammonium phosphate crystals during the growth of bacteria in media containing nitrogenous substances. SARA A. SCUDDER. Evans Memorial, Boston, Mass. *J. Bact.* **16,** 157–61(1928).—Crystals were sepd. from seven-day cultures in semi-solid agar, of *B. alkaligenes, M. catarrhalis* and *C. diphtheriae,* by melting the agar and washing with distd. water. They were preserved in 95% alc. They were mixts. of 2 and 3 compds. Compd. I had the optical properties of $NH_4MgOP_2O_6$, and compd. II those of $K_2Mg_2(SO_4)_3$. Compd. III was an unidentified

anisotropic substance which occurred as a minute fibrous aggregate too intergrown with other compds. to permit optical detn. The optical properties of single large crystals isolated from the different cultures identified them as $NH_4MgPO_4.6H_2O$. They also gave phosphate tests. Favorable factors for crystal formation are the presence of meat infusion, peptone, and inorg. phosphate, with a decrease in NaCl and moisture. A medium contg. peptone and phosphate without meat infusion is less favorable.

JOHN T. MYERS

The fermentation of glucose by organisms of the genus Serratia. CARL S. PEDERSON AND ROBERT S. BREED. *J. Bact.* **16,** 163–85(1928).—Two cultures of *Serratia marescens* formed the following products: acetic, formic, succinic, and levo-rotatory lactic acids, EtOH, acetylmethylcarbinol, 2,3-butyleneglycol, CO_2 and a small quantity of H. Two cultures of *Serratia indica* produced the same products except that no H was formed. A third strain produced the same things except that the lactic acid was inactive. A fourth strain differed in that the lactic acid was inactive and there were only traces of acetylmethylcarbinol or 2,3-butyleneglycol. There is a good bibliography.

JOHN T. MYERS

Studies on the proteolytic bacteria of milk. III. Action of proteolytic bacteria of milk on casein and gelatin. WM. C. FRAZIER AND PHILIP RUPP. Bur. of Dairy Ind. *J. Bact.* **16,** 187–96(1928); cf. *C. A.* **22,** 3428.—The action of 229 cultures of proteolytic bacteria from milk on casein and gelatin was studied. Four species of cocci and 4 of rods were found to cause no increase in amino N. The remainder fell into either low or high amino N groups. The Br test was positive in all cases of caseolysis except with *M. cereus*. *M. varians* was apparently unable to split Na caseinate but did break down Ca caseinate. Some of the other organisms seem to break down Ca caseinate easier than Na caseinate. Increasing amts. of fermentable sugar up to 0.1% did not appreciably affect the amt. of caseolysis by most organisms. With *M. percitreus*, however, caseolysis seems to decrease with increasing quantities of glucose. Caseolysis by the acid-forming *Streptococcus liquefaciens* seemed to be aided by more fermentable sugar. A study of the proteolytic milk organisms on casein and gelatin media is of value in grouping these organisms.

JOHN T. MYERS

The effect of surface tension upon the growth of the lactobacilli. W. R. ALBUS. Bur. of Animal Industry. *J. Bact.* **16,** 197–202(1928).—Fifty-eight strains of lactobacilli were studied. More than one-half the strains of *L. bulgaricus* were unable to grow in a medium in which the surface tension was depressed with Na ricinoleate to 42.6 dynes and none of the strains showed growth at 40.4 dynes after 7 days incubation at 38°. All the strains of *L. acidophilus* grew rapidly at the lowest surface tension employed, 40.4 dynes, as did a single strain of *L. bifidus*. The strains of *L. caseii* from Swiss cheese with one exception were inhibited at a higher surface tension than those from cheddar cheese or from milk. The ability of an organism, or group of organisms to grow at low surface tensions may be of value other than as a test method for differentiation. It may indicate fundamental differences in cell structure or metabolism.

JOHN T. MYERS

A comparative study of the action of sodium ricinoleate upon bacteria. ANTHONY KOZLOWSKI. N. Y. State Dept. of Health, Albany. *J. Bact.* **16,** 203–9(1928).—Streptococci from measles, erysipelas and scarlet fever were killed by Na ricinoleate at a diln. of 1:5000 in about 7 hrs. at 35°. Streptococci from other sources were less susceptible. Most streptococci were inhibited at a diln. of 1:20,000. Pneumococci under similar conditions were killed by a diln. of 1:10,000, and dissolved by 1:5000. No other organisms were dissolved by Na ricinoleate. Of the bacilli, *B. diphtheriae* was quite susceptible to the inhibitory, but much less so to the bactericidal action. *B. tuberculosis* was inhibited at a diln. of 1:2000. *B. paratyphosus*, *B. dysenteriae*, and *B. coli communis* were quite resistant to both the inhibitory and the bactericidal action. The bactericidal action of Na ricinoleate is conditioned by the sp. cellular resistance, the concn. of the soap soln., time, and temp. Na ricinoleate may be used instead of bile for dissolving pneumococci in routine diagnostic work. J. T. M.

Aromatogenic bacteria. K. P. MURATOVA. State Inst. Exptl. Med., Leningrad. *Arkh. Biol. Nauk.* **28,** 73–81(1928).—Eighteen strains of putrefactive organisms were isolated from stools of patients in the enteric epidemic of 1926. Sixteen of these strains were strongly proteolytic but inactive toward the sugars. Two strains were nonproteolytic but stongly fermentative. These have not been previously described.

W. A. PERLZWEIG

The preparation and testing of food gelatin for the bacteriological investigation of water as furnished to the outside by the Landesanstalt für Wasser-, Boden-, und Lufthygiene. HANS BEGER. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **3,**

162-75; *Chem. Zentr.* 1927, II, 1879.—B. describes down to the minutest detail the properties of the raw materials, and the methods of prepg. and testing food gelatins.

J. S. REICHERT

Toxic power of aniline color derivatives against microörganisms. A. CH. HOLLANDE AND MLLE. G. CRÉMIEUX. *Compt. rend. soc. biol.* 99, 542-4(1928).—The quantity of Nile Blue-HCl to be added to a culture medium of peptone 10 g., NaCl 5, H_2O 1000, to prevent all development of organisms was detd. and found to vary with the organism. Nile Blue was very active against the bacilli of Loeffler and of Koch, but, in comparison, only slightly active against the pyocyanic bacillus. Gram-positive bacteria are more sensitive to Nile Blue than are Gram-negative bacteria. The pharmacotherapic action of a dye for an organism infesting animal tissues will be influenced by the constituents of the cells and humors of the host, such as sugars, albumins, etc. L. W. RIGGS

Reduction of sulfates by microörganisms in the presence of fats. G. SELIBER. *Compt. rend. soc. biol.* 99, 544-6(1928).—The reduction of sulfates by microörganisms may take place in the presence of fat or its decompn. products as a source of energy and of C nutrition. The organisms which reduce sulfates, or the organisms which accompany them, decompose the fats in anaerobiosis. At the bottom of the sea the reduction of sulfates is made parallel to the decompn. of the fats. (Cf. Bastin, *C. A.* 20, 887; 21, 879.) L. W. RIGGS

The luminous organ of Euprymna morsei Verrill and the symbiotic luminous bacteria. TEIJIRO KISHITANI. Biol. Inst. Tokugawa. *Proc. Imp. Acad. Tokyo* 4, 306-9(1928).—From the lens of the luminous organ of the cuttlefish, *Euprymna morsei* Verrill, a new species of luminous bacteria was isolated to which the name *Pseudomonas euprymna* was given. The bacteria are Gram-negative short rods; they may be stained with the ordinary aniline dyes. They emit light of bluish green color on media contg. 3% NaCl. The optimum temp. is 15-25°. The bacteria were grown on media having a p_H of 7.0. They do not liquefy gelatin, coagulate milk, or hydrolyze starch. They reduce nitrate to nitrite. Glucose, fructose, galactose, and maltose are fermented under formation of acids, but without formation of gas. Indole is not formed in bouillon. No sporulation was observed. G. SCHWOCH

Physiological studies on the nitrogen-fixing bacteria of the genus Rhizobium. RUDGER H. WALKER. Iowa Agr. Expt. Sta., *Res. Bull.* 113, 371-406(1928).—Studies were made of some physiol. activities of the N-fixing bacteria of the genus *Rhizobium* to ascertain whether or not certain tests could be used for diagnostic purposes in sepg. the various cross-inoculation groups. The studies made include agglutination, gelatin liquefaction and fermentation of sugars and other C compds. The organisms used were chiefly of the alfalfa and sweet-clover, soy bean, pea, red clover and dalea groups. *Bacillus radiobacter* was also studied for purposes of comparison. Agglutination occurred in all homologous tests. In the heterologous tests agglutination occurred only when the organisms in question had been isolated from plants belonging to the same cross-inoculation groups. The results secured furnish strong evidence of a direct correlation between the groups of legume bacteria when they are classed according to their ability to cross-inoculate, and when they are grouped according to their serological reactions in cross-agglutination. The results of the fermentation studies in synthetic N-free media indicate that the legume bacteria attack monosaccharide sugars with a greater production of acid than they do the disaccharides or trisaccharides, the polyatomic alc. dulcitol, the benzene deriv. inositol or the polysaccharide dextrin. There is a wide variation among organisms of the same cross-inoculation group when they are compared upon the basis of their ability to change the reaction of sugar media. The variations among strains within a single cross-inoculation group in this respect are as great or greater than the differences between organisms of different groups. The growth of most of the organisms tested in media contg. N as peptone caused the reaction to become more alk. The variations in the quantity of acid or alkali produced in peptone media were wide, and as great between strains of a single group as between strains of different groups.

J. J. SKINNER

Respiratory pigment, cytochrome in bacteria. HIDETAKE YAOI AND HIROSHI TAMIYA. Tokyo Imp. Univ. *Proc. Imp. Acad. (Japan)* 4, 436-9(1928).—A close parallelism between the cytochrome content and the intensity of aerobic respiration holds in all bacteria examd. (relative concn. detd. spectroscopically). In almost all of the aerobic bacteria examd., cytochrome was always found with its 4 characteristic bands; *B. pyocyaneus*, *B. subtilis* and *B. cholerae* show most clearly the spectrum of cytochrome, very similar to that of baker's yeast. In the majority of the other bacteria examd., the band *b* is stronger (the band *c* is weaker or possibly absent) and the band *d* lies in the position of longer wave length (532 $\mu\mu$). In all strains of *B. dysenteriae*,

excluding the Shiga bacilli and *B. coli*, a characteristic extra band at 623–37$\mu\mu$ is found besides the known bands of cytochrome. C. J. West

The influence of anions and cations on the viability of Bacillus coli. C. H. Boissevain and Eric Webb. *J. Lab. Clin. Med.* **13**, 1027–35(1928).—The optimum concn. for the viability of the colon bacillus is $M/4$ in the case of nonelectrolytes and $M/8$ in the case of binary electrolytes. The H-ion concn. in PO_4 solns. is of small importance as long as it remains above p_H 5 and below p_H 8. Cations are without effect on the viability of the colon bacillus, except for a valency effect. The series of increasing toxicity for the anions is HPO_4^{--}, NO_3^-, Cl^-, SO_4^{--}, I^-. Their effect is purely additive; no evidence was found of "balancing" the toxicity of one ion by that of another. The HPO_4 ion is the only mineral constituent necessary for the life of the colon bacillus. Part of the toxicity of distd. H_2O and salt solns. may be due to the fact that they permit the diffusion of the HPO_4 ion out of the bacteria. The no. of colon bacilli remains const. in a soln. contg. a mixt. of NaH_2PO_4 and Na_2HPO_4 of p_H 7. The no. of bacilli increases if traces of org. material are present in the soln.; *e. g.*, cotton fibers or dead bacilli. Ethel W. Wickwire

The relative toxicity of gentian violet for certain members of the colon group of organisms. W. D. Stovall, M. Starr Nichols and Vera Vincent. *J. Lab. Clin. Med.* **13**, 1036–40(1928).—Gentian violet has a marked inhibitory effect on the growth of *B. coli* in a diln. of 1–20,000. In this strength it prevented growth in 90% of the methyl red and 50% of Voges-Proskauer cultures used in these tests. The inhibitory effect was evident on the methyl red-positive cultures in a diln. as high as 1–75,000, while it appeared not to affect the Voges-Proskauer-positive group until a very much lower diln. (1–30,000) was reached. The inhibitory action is noticed in the higher dilns. by the lag produced in the growth of the cultures. This lag effect is seen in the methyl-red-positive in much higher dilns. than in the Voges-Proskauer-positive cultures. There is a marked difference in the resistance of the 2 groups of organisms to the dye. Within the same groups there is variation in sensitiveness of the organisms to the action of the dye. E. W. W.

Microbiology of coals in the seam (Lieske, Hofmann) 21. Results of a systematic study of water from the Vistula (Kirkor) 14.

D—BOTANY

THOMAS G. PHILLIPS

Interrelationships of certain physicochemical constants of plant saps. Ross A. Gortner and Rachel Rude. Minn. Agr. Expt. Sta. *Proc. Soc. Exptl. Biol. Med.* **25**, 630–5(1928).—Calcns. were made to see if there was any direct relationship between the bound-water content of the plant saps studied by Meyer and any of their physicochem. properties. There were no high coeffs. of correlation found. This demonstrates that the measurement of bound water in a plant sap is the measurement of a factor essentially independent of the properties previously measured, and that the bound-water values cannot be obtained from any of the ordinary measurements. Detns. of the bound water may prove helpful in studying the properties of plant saps as related to geographical distribution. There is a marked difference in the physicochem. properties of the plant saps of the ligneous and herbaceous plant forms. C. V. B.

The absorption and utilization of plant nutrients. Walter-Ulrich Behrens. Univ. Königsberg i. Pr. *Z. Pflanzenernähr. Düngung Bodenk.* **11A**, 93–108(1928).—Vegetation expts. with oats plants in sand cultures and a const. renewal of the soln. by having the soln. run through the cultures are described. The app. consisted of a culture vessel with a reservoir (large bottle) so placed as to allow the nutrient soln. to be siphoned by drop into the culture. The culture vessel was provided with a proper outlet for the soln. The plants were analyzed for the different plant nutrients (N, K_2O, P_2O_5). The results show that the plant nutrients are absorbed from a N concn. of only 2.2 mg. per l. and from a P_2O_5 concn. of 0.65 mg. per l. as well as from more concd. solns. With the highest concns., the utilization decreases with increasing yield before the max. yield is reached. Nutrients can only be absorbed from dil. solns. with an expenditure of free energy which is supplied by certain chem. processes connected with the nutrient absorption. The affinity of these reactions is large in proportion to the free energy, which represents the difference in concn. between the active medium and cell sap. Inside the plant, the utilization of nutrients is not lower from very dil. soln. than from concd. solns. There is apparently a contradiction here in that generally the P_2O_5 from difficultly sol. phosphates is utilized very poorly in the plant. This

discrepancy is explained in that the nutrients from difficultly sol. combinations are available at a later stage of development of the plant than are the more sol. combinations. An expt. shows that the nutrient content of the plant depends very largely upon the time when the nutrients are absorbed. R. M. BARNETTE

The mathematical formulation of the action of plant nutrients. W. U. BEHRENS. Univ. Königsberg i. Pr. *Z. Pflanzenernähr. Düngung Bodenk.* **11A**, 150–5(1928).—In vegetation expts. with increasing applications of a plant nutrient, the following serve as a measure for the action of the plant nutrient: (1) the utilization of the plant nutrient, (2) the inner production's value (the proportion of the dry substance obtained to the amt. of plant nutrient taken up by the plant), and (3) the outer production value (the proportion of the dry substance obtained to the amt. of plant nutrient applied). All these values must be considered as functions of the "specific yields" (yield expressed as fraction of the max. yield). The course of these functions depends upon whether the nutrient is given in an easily sol. or difficultly sol. form. R. M. BARNETTE

The influence of salt solutions on the starch content of Drosera. ALFRED GIESSLER. *Flora* **123**, 133–90(1928).—Mature leaves of *Drosera capensis* ordinarily contain much starch in summer but during the winter they are quite starch-free. If cut leaves of this plant contg. starch are kept in an atm. satd. with water vapor, they do not lose their starch either in light or darkness. Thus treated, starch has been found present even after 45 days. Wilting favors the disappearance of starch. In this case after 1 or 2 days hardly any starch remains. If a paste prepd. from flies and saliva is placed on a starch-contg. leaf of *Drosera* and after 3 days this leaf is tested for starch, it is found that most of the starch has disappeared from beneath the spot on which the paste rested. It was also found that many salt solns. behaved similarly when drops of them were placed on *Drosera* leaves. Plants in pots under bell jars and also cut leaves in Petri dishes and leaves floated on salt solns. were used. Starch was tested for by the ordinary Sachs I method and the relative quantity of starch was judged by the depth of color produced. Fourteen common salts were used in 0.2, 0.1, 0.04 and 0.02 *N* solns. The effect of temp. was particularly studied. At 0–10° drops of salt solns. caused no starch disappearance; at 12–16° it was just noticeable; at 16–18° marked, at 18–36° very rapid, at 36–38° there was beginning of temp. injury to the leaf, at 38–50° the leaves were badly injured. The effect of common anions on starch disappearance is: $NO_3 > PO_4 > Cl > SO_4$. For anions, the ordinary lyotropic series is followed except it is in reverse sequence to the arrangement for most reactions of animal chemistry. Colorimetric detn. of p_H values showed that the effect of the salt solns. on starch digestion was noticeable both in weakly acid and weakly alk. media. It was further detd. with cut leaves fed with sugar solns. that starch formation in the leaf was hindered by salt solns. With leaf pastes, salt solns. were shown to bring about a slight starch break-down. In general, salt solns. increase the CO_2 output of cut leaves of *Drosera*. Expts. conducted with the exclusion of light and at const. temp. showed that certain salt solns. could cause a doubling of respiration intensity. In most cases, however, immediately after contact with the salt soln., respiration intensity was decreased for a time previous to the rise. Increased starch digestion in the presence of salt solns. may be explained on the basis of enzymic activation. Beech leaves were also tested with salt solns. and starch metabolism was found to be similarly affected. This behavior, therefore, is not limited to the leaves of carnivorous plants. R. C. BURRELL

Amphiteras antediluviana Ehrbg., and some contributions to the structure and development of diatom cells. WERNER LIEBISCH. *Z. Botan.* **20**, 225–71(1928).—Many investigators have assumed that the hard coating of diatom cells is composed of silicic acid impregnated with org. material. Tests with HF solns. which dissolve siliceous but not org. material showed no org. residue from the hard coating of this diatom. There is, however, an underlying membrane which appears to be composed of pectic material. Also the jelly-like cushions between the diatom cells give similar color reactions to those of pectic material. Much additional material of a purely botanical nature is included as method of culture, morphology of the cell, cell division, spore formation, etc. R. C. BURRELL

The influence of light and of glucose on the growth of a soil alga. B. MURIEL BRISTOL ROACH. *Ann. Botany* **42**, 317–45(1928).—Continuing studies on the C nutrition of algae isolated from soil (cf. *C. A.* **20**, 2180; *Ann. Botany* **41**, 509–517), R. attempts to answer the question whether soil algae contribute to the fertility of the soil by adding org. matter or detract therefrom by immobilizing nitrogenous matter otherwise available for crops. *Scenedesmus costulatus*, var. *chlorelloides* was grown under

controlled aeration in parallel cultures with mineral salts plus glucose in the dark and light, and with mineral salts alone in light, thus permitting measurement of the effect of photosynthesis upon the rate of increase in bulk. The intensity of the light supplied was varied over a wide range, with the result that growth increased directly with increased intensity up to a definite limit beyond which no significant increase in growth rate occurred with increasing light. At high light intensities, nutrition is purely photosynthetic, no increase in rate of growth occurring when glucose is added to the medium. At low light intensities, the total growth with glucose present approximates the sum of growth in light on mineral salts plus that in dark on glucose. In the lower layers of the soil, the organism grows at the expense of the directly available org. compds. present; at the surface it will be self-maintaining by photosynthesis or will draw in varying degree upon the available org. matter of the soil according as the light may vary in intensity. In *Chlorella* and *Cystococcus* spp. the semi-saprophytic habit is much more firmly established. JOSEPH S. CALDWELL

Relations among the individual properties of barley (corn), and the influence of the weather on the nitrogen content. G. STIEHR. *Allgem. Brauer- u. Hopfen.-Ztg.* **67,** 1032–3; *Chem. Zentr.* **1927,** II, 1766.—Extensive data already available are surveyed and compiled in diagrams to render them more easily accessible, especially for the comparative value in the future. Reference is made especially to the surprising differences in the N content of 2 seasons of barley. Conclusion: Weather plays a part in the vegetation period of barley. C. C. DAVIS

The action of silicic acid in increasing the yield of crops. WALTER OBST. *Kunstdünger Leim-Ind.* **24,** 345–6; *Chem. Zentr.* **1927,** II, 2001.—A summary of earlier expts. on the part played by SiO_2 in the nutrition phenomena of plants. C. C. DAVIS

Microchemical investigation of the structure of the collenchymatous cell wall. DONALD B. ANDERSON. *Sitzb. Akad. Wiss. Wien, Abt. I,* **136,** 429–39(1927).—Chem. and phys. tests indicate that the cell wall of the collenchyma of *Solanum lycopersicum* possesses an homogeneous structure. Its angular thickening consists of a leafy structure composed of lamellas which are built up alternately of pectin and cellulose material. Normal untouched collenchyma shows double refraction between crossed nichols. After treatment with copper ammonium hydroxide which removes the cellulose the cell wall becomes isotropic. Only pectin material remains in the cell wall after removal of the cellulose. Treatment of the collenchyma with H_2SO_4 and KI clearly shows a stratification of the lamellas. The layer structure of cellulose and pectin accounts for the following facts: (1) the high water content of the cell wall, (2) the powerful contraction of the thickened angles in the radial direction when placed in dehydrating agents and noteworthy expansion when placed in water, (3) the loss of high water content and shrinkage on heating, (4) the diverse views of various investigators regarding double refraction of the collenchyma and, finally, the great elasticity of the cell wall. L. T. FAIRHALL

Preliminary report on amino acid synthesis in plants. WALTER F. LOEHWING. State U. of Ia. *Proc. Iowa Acad. Sci.* **34,** 115–8(1927).—It appears that fruit formation robs vegetative structures of normal tomato plant of nitrates, ammonia and amino acids. When defruited plants are supplied with nitrate fertilizer, the nitrates are absorbed as such, accumulate at and are actively reduced in the vicinity of meristem, to nitrites, ammonia and amino acids. This reduction is most marked in alk. tissues about the pericycle. In fact, if the behavior of the expressed sap be employed as a criterion, it appears that this alky. and the presence of sugars are indispensable for nitrate reduction and amino acid formation. The steps in the process, then, are: nitrates to nitrites to ammonia to amino acids in presence of sugars. Reduction is not enzymic as boiled expressed sap reduces as efficiently as unboiled. Investigation is under way to det. the nature of the reducing agent, which is apparently bound up with the occurrence of carbohydrates. A short bibliography is appended. W. G. GAESSLER

Studies on pectin. III. The degree of esterification of pectin in the juice of the lemon. ARTHUR G. NORMAN. Univ. Birmingham. *Biochem. J.* **22,** 749–52(1928); cf. *C. A.* **22,** 2766.—The figures for methoxyl in the purified pectin approach the theoretical value for tetramethylpectic acid. BENJAMIN HARROW

Effect of temperature on the permeability of protoplasmic membrane. B. SEN. Vivekananda Lab., Calcutta. *Proc. Roy. Soc.* (London) **B103,** 272–88(1928).—The permeability of the plasma membrane in plant cells to ions first increases with rising temp. In some species, the permeability scarcely changes between 30° and 40°. The permeability then decreases between 35° and 40° and the lethal temp. At the lethal temp., the plasma membrane becomes highly permeable, an irreversible change. JOSEPH S. HEPBURN

Investigations of the cell-wall substances of plants with special reference to the chemical changes taking place during lignification. E. J. CANDLIN AND S. B. SCHRYVER. Imperial Coll. Sci. and Technology. *Proc. Roy. Soc.* (London) **B103**, 365–76(1928).—The cell walls of plants contain cellulose, lignins, hemicelluloses and pectins. The hemicelluloses and pectins are formed by conjugation of sugars and sugar acids (*uronic acids, i. e.,* glucuronic and galacturonic acids); hence they form a distinct chem group, the *polyuronides*. The pectins are richer in uronic acids than the hemicelluloses, while these acids do not occur in the lignins. When treated with dil. alk. solns., pectins undergo decarboxylation even at room temp.; among the products are hemicelluloses. No direct connection has been traced between pectins and lignins. Non-lignified plant tissues contain relatively large amts. of pectins, small quantities of hemicelluloses and no lignin. Lignified tissues contain relatively large amts. of lignin and hemicelluloses, and only traces (if any) of pectin. Apparently, decarboxylation occurs during lignification. JOSEPH S. HEPBURN

A method for the study of chromosomes in pollen-mother-cells. JOHN BELLING. *Univ. California Pub. Botany* **14**, 293–9(1928).—A histochem. method for the study of the chromosomes during mitosis is described. For fixing and staining, use is made of (1) a soln. contg. CrO_3, glacial AcOH, and HCHO in the proportion 1:10:16 or 1:10:8; (2) a soln. of $Fe^{+++}NH_4$ alum, and (3) an alc. soln. of brazilin. For the details, reference must be made to the original paper. JOSEPH S. HEPBURN

The metabolism of variegated leaves. WALTER SCHUMACHER. Bot. Inst. der Univ. Leipzig. *Planta Abt. E., wiss. Biol.* **5**(2), 161–228(1928).—A chem. analysis of white and green tissues of variegated leaves gave the following differences for the white as compared with the green portions: less total N, less protein N, greater sol. N, less carbohydrates, greater peroxidase and less catalase content. When leaves of *Acer negundo* and *Cornus alba* were placed in a sugar soln., the white tissue showed an increase in protein N ranging from 2 to 20 times the slight increase for the green areas. Other N fractions showed a decrease or no change in value A lower rate of respiration occurred in the white than occurred in the green tissue, but the respiration quotient (CO_2/O_2) was the same for both, *i. e.*, equal to approx. unity. A considerable portion of the paper is devoted to the nature of the physiol. processes involved during greening. In the dark greening occurred more rapidly at a high temp. (20–35°) than at a low temp. (3–5°). The importance of temp. as a factor in the greening process is emphasized by S. Future work on variegation, it is believed, should pay special attention to temp. effects. A. E. HITCHCOCK

Origin of starch in the potato. H. COLIN AND R. FRANQUET. *Bull. soc. botan. France* **74**, 451–8(1927); cf. *C. A.* **22**, 4151.—Reducing sugars, sucrose, and starch were detd. for the leaf, petiole, stem, and tuber of the potato. In all parts of the plant sucrose was found constantly associated with starch. The ratio of reducing sugars to sucrose varied considerably not only in different parts of the plant, but also in the same parts at different stages of growth without a corresponding change in starch content. Intermediate products between starch and sucrose were not detected. The authors see no reason for assuming a direct origin of starch from sucrose. Theories relating to the origin of starch are discussed in connection with the data presented. A. E. HITCHCOCK

Occurrence and distribution of pectic warts. JOS. KISSER. *Jahrb. wiss. Botan.* **68**, 206–30(1928).—The presence or absence of pectic wart-like swellings on the cell walls of plants is suggested as a possible systematic character to be used in classification. These swellings usually occur on the side of the wall which is exposed to intercellular spaces. In addn. to an extensive review of the literature (48 references being cited) K. has added 161 species to the list of plants which have been examd. for these swellings. Of this no. 46 species contained the pectic warts. Certain spherical swellings known as slime balls are considered to be closely related to the pectic warts. Both types give the pectic reaction and both have a similar location on the cell walls. Before being subjected to the test reactions, the sections were first treated for 30 min. in Javelle water in order that the swellings would remain permanently fixed. The following 3 reactions were used for the identification of the pectic substances in the swellings: (1) soly. in dil. soln. of HCl with subsequent addn. of dil. NH_4OH (unless heated the warts would merely swell up); (2) soly. in 3% H_2O_2 at 50°; (3) color reaction with Ruthenium-red (red). It is not known what physiol. role these swellings may have. A. E. HITCHCOCK

Influence of geotropic stimulation on the sugar and acid content of shoots. THEO. WARNER. Pflanzenphysiol. Inst. der Univ. Berlin. *Jahrb. wiss. Botan.* **68**, 431–96 (1928).—In geotropically stimulated shoots of *Helianthus annus, Silphium perfoliatum,*

Dahlia variabilis, and the potato the lower side was found to contain more reducing sugars than the upper side. Increasing the period of stimulation produced greater differences (ranging from 1 to 50%) in the amt. of reducing sugars, at least for periods up to 18 hrs. and in some cases up to 144 hrs. Passive bending not due to geotropic stimulus failed to produce similar changes in reducing sugar content. Methods used by previous investigators in connection with similar expts. are criticized on the grounds that the methods were not sufficiently accurate to det. small amts. of reducing substances. The author followed the methods of Rupp and Lehmann (1909) and Hertzfeld (1912) for detg. reducing substances. The first named method depends upon the reaction in which free I is produced in the presence of KI by the action of the unreduced Cu in Fehling soln., and the subsequent titration of I with $Na_2S_2O_3$. Using 1 to 2 g. samples a difference of 1% in reducing sugars could be detected by this method. The second method is based on the fact that in an alk. soln. aldose and ketose sugars reduce methylene blue. Max. differences in reducing sugar content were obtained when the shoot was placed at from 90° to 135° from the vertical, a sharp decline resulting for angles greater than 135°. The free acid content was greater in the upper side than in the lower side. No correlation existed between the acid content and the duration of the period of stimulation. No difference in water content was obtained for the 2 sides of the shoot. The osmotic value of the cell sap was the same on both sides in spite of the fact that the lower side of the shoot contained a higher concn. of reducing sugars. The significance of the difference in reducing sugar content as a result of the geotropical reaction is therefore still not understood. A. E. HITCHCOCK

Nitrogen bases in the protein catabolism of higher plants. GUSTAV KLEIN AND MAX STEINER. Pflanzenphysiol. Inst. der Univ. der Wien. *Jahrb. wiss. Botan.* **68,** 602–703(1928).—NH_3 and volatile amine detns. were run on the floral parts, and in some cases on the leaves, of approx. 100 species of higher plants. NH_3 was found in the distillates of all plants examined, and the amines in the distillates of 42 out of 103 species. The following amines were found in amts. ranging from 0.0005 to 0.2 mg. per 100 g. fresh wt.: methyl, dimethyl, trimethyl, *i*-amyl, and *i*-butyl. The special methods necessary for micro-analytical detns. are fully explained in the review of literature which includes 165 references to all phases of the work discussed by the authors. Identification of the amines is based on crystal form, color reaction and m. p. An approx. quant. value is arrived at by comparison with a key worked out for known amts. of pure amines. It is pointed out that these volatile amine bases are of considerable biological importance both as the principal constituent of insect attrahents in flowers and as a possible use in the systematic classification of plant species. A. E. HITCHCOCK

Content of calcium and magnesium of some plants in the Mediterranean region. E. CANALS AND G. DAUCAN. *Bull. soc. chim.* **43,** 779–84(1928).—Most of the phanerogams examd. contain more Mg in the leaves than in the roots. Xerophytic plants are lower in Mg than the hygrophytes. The grasses from the salty lands are relatively low in Mg. Ca increases with the age of the leaves. The variations in Mg content are less, except in *Sedum altissimum,* where the proportion of Mg found in the plants collected in Oct. is about one-third of that in March. H. R. KRAYBILL

Carbohydrate changes during the ripening of plantains. S. RANGANATHAN, JR. *J. Indian Inst. Sci.* **11A,** Pt. 7, 80–3(1928).—Exts. prepd. from ripening plantains and the tannin-free pulp failed to show diastatic activity. The results confirm those of Falk and McGuire (*C. A.* **15,** 2454) in contrast to those of Tellarico (*C. A.* **2,** 2105) and Bailey (*C. A.* **7,** 1066). H. R. KRAYBILL

The carbon/nitrogen ratio in the wheat plant. PHYLLIS A. HICKS. *New Phytologist* **27,** 1–46(1928).—A study of the C/N relations was made throughout the life history of 3 strains of wheat of different lengths of growth periods. Total C and N were estd. by microanalytical methods. All strains under similar conditions produced embryos with similar C/N ratios regardless of the actual amts. of C and N. Early stages of germination show a low C/N ratio. A low C/N ratio is associated with vegetative activity. The C/N ratio rises steadily throughout the period of vegetation and when a sufficiently high ratio is reached flowering occurs. Each strain has its own distinctive C/N ratio at which flowers are initiated. Conditions for the initiation of flower primordia (high C/N, low N) are the reverse of those required for fruit development (low C/N, high N). The younger the tissues, the lower the C/N ratios are. H. concludes that the results strongly support the statement of Kraus and Kraybill that "Fruitfulness is associated neither with the highest nitrates, nor the highest carbohydrates, but with a condition of balance between them." H. R. KRAYBILL

Distribution of carbon/nitrogen ratio in the various organs of wheat plant at

different periods of its life history. PHYLLIS A. HICKS. *New Phytologist* **27,** 108–23 (1928).—The C/N relations were studied in detail in different parts of the Starling strain of wheat at 3 stages; the seedling, the vegetative and the fruiting stage. The C/N ratio decreases in value from bottom to top of the stem. C remains rather const. throughout the stem and the N decreases from top to bottom. The results confirm a previous statement by the author that "the younger the tissue, the lower the C/N ratio." H. R. KRAYBILL

Maintenance of semi-permeability in the plant cell during leaching experiments. F. C. STEWARD. *Proc. Leeds Phil. Lit. Soc.*, Sci. Sect., I, Pt. 6, 258–70(1928).—An app. for leaching beet root slices under sterile conditions is described. Evidence is given showing that leaching phenomena applied to living tissues do not afford a means of detg. the chem. nature of substances present in the cell walls or limiting protoplasmic surface of plant cells. Prolonged leaching expts. indicate that such treatments do not necessarily result in loss of semi-permeability. Bibliography of 41 citations is given. H. R. KRAYBILL

The effect of mosaic on the globulin of potato. MAYME DVORAK. *J. Infectious Diseases* **41,** 215–21(1927).—With the precipitin test it was found that the globulins of the cell sap and cytoplasm from healthy potato plants reacted differently from those from potato plants infected with mosaic, indicating that the changes in the globulins were due to the action of the disease. JULIAN H. LEWIS

Studies in the physiology of fruit trees. II. The effects of ringing, double ringing and dis-budding upon the starch content and cambial activity of two-year-old apple shoots. THOMAS SWARBRICK. Univ. of Bristol Agr. Research Sta. *J. Pomology Hort. Sci.* **6,** 296–312(1928); cf. *C. A.* **21,** 3650.—In appls-tree shoots starch disappeared above, but not below, the rings in early May. Xylem formation began earlier above the rings than below them. About June 8 starch began to accumulate above the ring and disappear below. Lateral outgrowths and xylem formation also appeared below the rings at the same time. Later, starch was extremely abundant above the rings which did not heal Where rings healed the amts. of starch above and below were equal. The starch cycle and cambial activity were normal in sequence but delayed between 2 rings. No starch disappeared between disbudded rings until the middle of July but it was accumulating above the upper ring. No xylem formed between disbudded rings Healing of the rings caused starch to disappear and xylem to form. Shoots disbudded, except for terminal bud, had almost normal starch cycles and cambial activities. Starch did not disappear from completely disbudded shoots until very late in the season. Subsequent bud development invariably caused starch to disappear and xylem to form below the origin, but not above such buds. Starch disappearance was complete, irrespective of vigor. A temporary disappearance of starch especially from the phloem during winter was established. It reappeared prior to the beginning of spring growth. Developing buds appear to play an important role in the initiation of cambial activity and starch disappearance in woody stems in spring. Starch disappearance in spring begins in the xylem before cambial activity is very far advanced and cambial activity ceases in the fall when starch accumulates. Slowing down of elongation growth was accompanied by a marked starch accumulation in the stems. 25 references are given. A. L. MEHRING

The action of a deficiency of water on the protein exchange in higher plants. KURT MOTHES. Botan. Inst. Univ. Halle. *Ber. deut. botan. Ges.* **46,** General Meeting Number, 59–67(1928).—In plants low in water the older leaves wilt first. In these leaves there is protein decompn., even in the presence of sufficient carbohydrates, and the products are in part oxidized, and in part translocated to younger leaves. Expt. shows that wilted leaves show greater protease activity than similar turgid leaves. In wilting there is at first an increase in respiration and then a decrease below normal. LAWRENCE P. MILLER

Crown plasmolysis. KARL HÖFLER. *Ber. deut. botan. Ges.* **46,** General Meeting Number, 78–82(1928).—Working with the epidermis of the bulb of *Allium cepa*, H. observed what he called crown plasmolysis, characterized by the protoplast appearing in 3 sep. portions, a deep red vacuole space and 2 transparent, hyaline, colorless, crown-shaped constituents on both sides. This type of plasmolysis is produced by K, Na, and Li salts, not by Ca, Ba, Sr, Mg and NH_4 salts nor by any org. substances investigated. The action of Ca is antagonistic to that of K so that if to a soln. of KNO_3 or KCl, $^1/_{25}$ to $^1/_{50}$ of its vol. of Ca salt is added no crown plasmolysis occurs. Sr and Ba act similarly but $MgCl_2$ even if present in the ratio of 2 pts. KCl to 1 pt. $MgCl_2$ does not prevent plasmolysis. LAWRENCE P. MILLER

Narcosis of carbon dioxide assimilation and the method of counting bubbles.

TH. SCHMUCKER. *Biochem. Z.* **195**, 149–60(1928).—CO_2 assimilation is a process very sensitive toward narcosis. Stimulation occurs only seldom and is not very marked. Usually the effect is an injury of prolonged after-effect. The findings of a strongly stimulating action of CH_3CHO could not be verified. The narcotic effect, *i. e.*, the reversibly inhibiting concns., are: for $CHCl_3$ 0.025–0.100%; for EtOH 1–3 vol. %; for Et_2O 0.2–2.5%. S. MORGULIS

Biochemistry and physiology of phosphorus compounds in plants. I. Exosmosis of phosphorus compounds. V. ZALESKII AND V. MORDKIN. Plant Physiol. Lab., Charkow. *Biochem. Z.* **195**, 415–20(1928).—The exosmosis of organically bound P and of phosphates was studied on living plants. Permeability varies considerably. Resting seeds allow much more organic P to pass out than either germinating or unripe seeds. Ripening is accompanied by an increase and germination by a decrease of permeability. The extent of exosmosis of P compds. depends upon their amt. and mode of combination in the plant cell. It is not regarded as probable that the phosphatides which diffuse into the water belong entirely to the membranes. S. MORGULIS

The distribution and properties of resinous substances in various parts of the trunk of pine trees (Pinus silvestris) according to seasons. I. V. FILIPOVICH AND V. A. VUISOTZKII. *J. Chem. Ind.* (*Moscow*) **4**, 953–60(1927).—A systematic chem. study was undertaken to abolish the crude empiricism reigning in the industry of tapping resinous substances and to elucidate the mechanism of formation of the latter, as well as their role in the life of the tree. The heartwoods and the sapwoods were sepd., cut into small pieces in the direction of the grain and their respective resinous materials were extd. separately with Et_2O in a Soxhlet app. The resinous material extd. from the heartwood is clear yellow; that from the sapwood is greenish. The former is much less stable than the latter, being more apt to form cryst. ppts. on standing in air; these ppts. are evidently products of chem. alteration, since their acid and sapon. nos. are always higher than those of the original substances, whereas the acid and sapon. nos. of the mother liquors remain practically unchanged. These ppts. cannot be redissolved in their mother liquors by mere warming. The acid nos. of the heartwood resinous material are, for samples cut in wintertime, generally higher than those of the sapwood material, but in midsummer the difference is not so great. The difference between the sapon. coeff. and the acid number is generally insignificant (0–8) for heartwood resinous material; for sapwood resinous material it is always much larger (6–28). As a rule the content of components which can be sapond. and salted out (cf. *C. A.* **22**, 3541) is less for sapwood resinous matter than for heartwood resinous matter, whereas its unsaponifiable content is higher. The non-volatile residues of steam distn. (rosins) from heartwood are viscous liquids which do not solidify at —14°; from sapwood the resinous material from lower parts of the tree is a solid whose m. p. depends on the season of the cutting and on the height at which it has been made. The acid no. of the heartwood rosin varies with the season only from 132 to 163; that of the sapwood rosin fluctuates between 52 and 151. The quantity of substances which can be saponified and salted out is for the heartwood rosin always higher than its unsaponifiable matter; it may be lower for sapwood rosin. The rosins vary in compn. according to the height on the tree at which the cutting is made. The content in components which can be saponified and salted out apparently decreases, for the winter rosins, with the height of the cutting, but the acid nos. (172–176) and the sapon. coeffs. (175–178) of the same samples remain almost const., whereas in the original resinous materials from which these rosins were derived the fluctuations according to height are considerable, though irregular. The amount of unsaponifiable (which apparently consists of heavy terpenes) increases with the height of the cutting from 7.34% at the level of the ground to 9.70% at the height of 8.34 m. and its chem. consts. vary. The resinous substances of the trees migrate from place to place and also vary in compn. in the course of the year. In the countries where the winter is cold and the sapwood freezes, the main mass of resinous substances concentrates in the uncongealed heartwood. The m. ps. of the rosins derived from the heartwood are lower in summer; the sp. grs., both for heartwood and sapwood, rise in midsummer and drop in autumn; the angle of rotation is negative in winter and positive in summer; finally the acid and sapon. nos., as well as the % of substances which can be salted out, are also strongly affected by the seasons. BERNARD NELSON

Study of the amylase of some green plants. ADRIEN GOFFAUX. Inst. Carnoy. *Bull. trimestr. assocn. élèves école sup. brasserie univ. Louvain* **28**, 74–80(1928).—The expts. described show that the leaves of Leguminosae contain more amylase than those of the potato plant, annual *Mercurialis* and Gramineae (rye and millet); that the stems also contain amylase but in smaller quantity than the leaves; and that under

given exptl. conditions the rate of hydrolysis by a given ext. of fresh or dried leaves of pastes prepd. from different starches varies but the final product is always maltose.
A. Papineau-Couture

The decrease in alkaloid content in plant parts in the drying process. H. Metsapa. *Pharmacia* **1926**, No. 5, 7 pp.; *Chem. Zentr.* **1927**, II, 1489.—Various parts of the plants cultivated in Dorpat, *Atropa belladonna, Hyoscyamus niger, Datura stramonium, Conium macalatum, Nicotiana tabacum* and *Nicotiana rustica,* were studied for alkaloid content in various periods of vegetation. The data are compiled in tables and show that all plant parts under investigation lost a part of their active principle on drying. The loss varies with the vegetation period and with the year. It is generally greater with the larger water content. The highest loss occurs with the roots, then with the stems and leaves. The lowest loss is with the seeds. The highest loss is with *Hyoscyamus,* then *Datura, Belladonna, Nicotiana* and least with *Conium.* The loss in total alkaloid content varies between 2 33 and 92.49% except in the case of the *Stramonium* stems. The highest alkaloid content is present, in general, in the roots before and after the vegetation period, the stems at the start of the blossoming period, the leaves of *Belladonna* in the first half of the blossoming period, the *Hyoscyamus* and *Datura* in full bloom and the *Conium* toward the end of the blooming period. The least alkaloid was present in the plants of 1923. The plants under investigation compared favorably in alkaloid content with plants of other countries. J. S. Reichert

Some experiments and considerations in the realm of the biomechanics of plants. Bohuslav Stempel. *Sbornik Ceskoslov. Akad. Zemedelske* **2**, 1–25; *Chem. Zentr.* **1927**, II, 945.—S. detd. the vegetation factor (the time) in the course of which the function factor (the amt. of nourishment given to the plant) was varied. The effects of the NO_3 *ion* and the PO_4 *ion* are opposite in so far as the first promotes the formation of chlorophyll while the second favors early maturity by lessening the possibility of utilizing the assimilation process. If each of these ions influenced only one pair of the function factors then the application of nitrate fertilizer during the vegetation period would have to increase the yield, and following fertilization with superphosphate would have to lower the yield to a definite extent. Since, however, both ions influence several pairs of function factors, whose effect can be combined in various ways, both an increase and a decrease in yield can be obtained depending upon the time of applying the fertilizer and the reactivity of the plant. These results have been confirmed in field tests with potatoes. J. S. Reichert

The effect of radioactivity on the chlorophyll-containing and the non-chlorophyll-containing cells. Julius Stoklasa, Josef Penkava and Josef Bares. *Sbornik Ceskoslov. Akad. Zemedelske* **2**, 57–104; *Chem. Zentr.* **1927**, II, 945–6.—The authors prove that the presence of Rn streaming from the soil into the atm., by the emission of α-rays, greatly increases the intensity of respiration both in the chlorophyll-contg. and the non-chlorophyll-contg. cells, particularly with a content of 262–83 Mache units in the atm. The production of CO_2 is increased about 40–90%. The α-rays accelerate all the enzymic processes, if O_2 is present in sufficient quantities. The β- and γ-rays activate principally the glucolytic enzyme. These rays are also held responsible for the intensive respiration of the organisms which are rich in K. A decompn. of *carbohydrates* ensues with the formation of *lactic acid, alc.* and CO_2. The alc. gives rise to AcH and AcOH. The α- and β-rays have in some respects an opposite effect. The β-rays activate the surface and promote synthetic action, while the α-rays promote the decompn. of complexes and act destructively and probably by the isolation of org. Fe groups they promote oxidation. J. S. Reichert

The death wave in Nitella. I. Applications of like solutions. W. J. V. Osterhout and E. S. Harris. Rockefeller Inst. *J. Gen. Physiol.* **12**, 167–86(1928).—Expts. on injury of *Nitella* cells by cutting show that the current of injury will be positive when the cell is in contact with concd. solns. and negative in contact with dil. solns. of KCl. The results support the theory that protoplasm is composed of layers differing considerably in their properties, each having a death curve of simple, regular form. The more rapid alteration of the outer layer makes the protoplasm more positive; the more rapid alteration of the inner layer makes it more negative. From the point of injury a death wave passes along the cell, setting up at each point touched by it a death process which has the greater speed and intensity the nearer it is to the source of injury. C. H. Richardson

Spectrophotometric studies of penetration. IV. Penetration of trimethylthionine into Nitella and Valonia from methylene blue. M. Irwin. Rockefeller Inst. *J. Gen. Physiol.* **12**, 147–65(1928).—Spectrophotometric measurements show that the sap of these plant cells if placed in methylene blue soln. at p_H 9+ contain chiefly trimethyl-

thionine, irrespective of the time the measurements are taken. Methylene blue is present in the sap only when the cells are injured or when it enters at the time the sap is extd. The sap cannot demethylate methylene blue. It is uncertain whether the trimethylthionine has penetrated from the external methylene blue soln., which generally contains this dye as an impurity, or whether it is formed from methylene blue by the protoplasm. The theory is discussed on the basis of the more rapid penetration of trimethylthionine as free base than as methylene blue or trimethylthionine in salt form. Other contributions will follow. C. H. RICHARDSON

Positive and negative currents of injury in relation to protoplasmic structure. W. J. V. OSTERHOUT AND E. S. HARRIS. Rockefeller Inst. *J. Gen. Physiol.* **11**, 673–700(1928).—In simple, multinucleate cells of *Nitella*, the current of injury may be pos. or neg. With $CHCl_3$ in 0.1 *M* KCl it is pos. but with 0.001 *M* KCl it is neg. Each protoplasmic layer probably has a death curve of simple, regular form, the more rapid alteration of the outer layer producing a pos. current, the more rapid alteration of the inner layer, a neg. current of injury. C. H. RICHARDSON

Citric acid inversion of sucrose in plant tissues. J. E. WEBSTER AND C. DALBOM. Oklahoma Agr. and Mech. Coll. *Science* **68**, 257–8(1928).—In expts. using HCl, invertase and citric acid, resp., as hydrolyzing agents of the sucrose in grape stem and leaves and in the *Coleus*, the HCl with solns. contg. glucosides (grape stems) gave too high results, and with solns. contg. little of glucosides and only a trace of sucrose, gave too low results. Invertase failed to give consistent results. Citric acid was easy to use, consistent in results, and apparently did not hydrolyze glucosides nor destroy any of the invert sugar. L. W. RIGGS

The effect of ethyl alcohol on the turgor pressure of Spirogyra. V. V. LEPESCHKIN *Am. J. Botany* **15**, 422–4(1928).—Weak concns. of alc. decrease the turgor pressure of *Spirogyra* while strong concns. increase this pressure. The increasing effects of stronger concns. of alc. must be ascribed to a very strong rise of the concn. of cell sap of the alga. Its cell sap contains much tannin which forms a colloidal soln. in water, but the solns. of tannin in dil. alc. are mol. Alc. penetrates the cell sap, dissolves tannin molecularly and increases its mol. concn. The method of isotonic coeffs. shows that the decreasing effect of small concn. of alc. on the turgor pressure of *Spirogyra* is produced by the increase of the permeability of protoplasm. The results show that all narcotics lower permeability as narcosis is brought about by a slight chem. decompn. of the principal substances of protoplasm. J. J. SKINNER

Tobacco frenching—a nitrogen deficiency disease. W. D. VALLEAU AND E. M. JOHNSON. Ky. Agr. Expt. Sta., *Bull.* **28**, 179–253(1927); cf. *C. A.* **21**, 117.—Frenching of tobacco is a disease characterized by chlorosis of the leaf tissue between the veins or, in severe cases, the entire growing point may be chlorotic. In pot expts. the disease usually appears in the growing point at about the time N starvation begins to appear in the lower leaves. It is readily controlled by the addn. of N to the soil in any of the readily available forms as $NaNO_3$, KNO_3, urea, ammonia compds., etc. Control extends over a long or short period depending upon the amt. of N added. Pecan rosette, apple rosette, frenching of citrus and certain other chloroses present aspects so similar to frenching of tobacco as to suggest that they are diseases of the same nature. Fifty-two p. p. m. of NO_3 added every 2 weeks to soil in which plants were beginning to show N starvation was not sufficient to prevent frenching, while with the addn. of 104 p. p. m. at the same intervals the plants became dark green and did not french. Frenching has developed in sand cultures soon after the plants showed signs of N starvation. The addn. of 40 p. p. m. of NO_3 in sand was not sufficient to result in healthy plants while the addn. of 80 p. p. m. resulted in a healthy, dark green growth. Heating the virgin soil to 65° has the same effect on the growth of tobacco plants in pot cultures as the addn. of available N; the plants grow much larger before showing signs of N starvation than when grown in the unheated soil, and usually do not french, even after N starvation becomes prominent. CaO added to virgin soil in large quantities stimulated growth of tobacco plants over those in untreated soil and appeared to prevent frenching, although N starvation eventually developed in the lower leaves. The stimulation was much less than that resulting from heating the soil to 65°. Plants in soil to which CaO had been added grew more slowly, and developed N starvation in the lower leaves at about the same time as the others but gradually outgrew them and did not french. Evidence is presented which suggests that drouth spot, cork spot and bitter-pit of apples and blossom-end rot of tomatoes are diseases of the same general nature as frenching and are due to N starvation of the affected tissues. The theory is advanced that brown bark spot of apple and other trees is a disease due to N starvation. J. J. SKINNER

The growth of cotton in various nutrient solutions. HORACE J. HARPER AND HENRY F. MURPHY. Oklahoma Agr. Expt. Sta. *Soil Science* **26,** 139–45(1928).—A study was made of the growth of cotton plants in sand cultures to which 9 different nutrient solns. were added. In 3 different tests Tottingham's soln. produced the most satisfactory growth of cotton although in one instance Shive's soln. produced a slightly larger plant but did not produce a normal development of squares and bolls. Pfeffer's nutrient soln. produced a very satisfactory growth of cotton and because of its lower salt concn. may be preferable under certain conditions to either Tottingham's or Shive's soln. The utilization of rock phosphate by the cotton plant was very poor when substituted for monopotassium phosphate in Pfeffer's soln., even though a considerable amt. of insol. P was transferred to the sand culture when the soln. was added. Since the absorption of Fe by the cotton plants grown in different solns. was not in proportion to the amt. of Fe present in the soln., an excessive amt. of Fe in Crone's nutrient soln. does not explain the poor growth of cotton produced by that soln. A table is given showing the compn. of the nutrient solns. used. J. J. SKINNER

The selective absorption of inorganic elements by various crop plants. J. D. NEWTON. Univ. of Alberta. *Soil Science* **26,** 85–91(1928).—Sunflowers, beans, wheat, barley, peas and corn were grown in nutrient solns. and in a loam soil and their compns. detd. Plants grown in the culture solns. were richer in nutrients, Ca, K, Mg, N and P than plants in loam soil. Sunflowers were high in Ca and Mg and moderately so in K and P. Beans were high in Ca and Mg and moderately high in P and poor in K. Peas, barley and wheat were somewhat similar in org. elements. Corn was low in inorg. elements as compared to the other plants. J. J. SKINNER

Variations in the manganese content of certain vegetables. W. H. PETERSON AND C. W. LINDOW. Univ. of Wisconsin. *Soil Science* **26,** 149–53(1928).—The Mn in 22 samples of cabbage, 13 samples of green peas, 18 samples of string beans and 4 samples of tomatoes was detd. On the fresh basis the av. is as follows: cabbage 0.000076%, green peas 0.00032%, string beans 0.00034% and tomatoes 0.000091%. Variations of from 200 to 300% were found among the samples of each class of vegetables. These variations do not appear to be correlated with the type of soil in which the samples were grown. They are probably related to the amt. of available Mn in the soil rather than to the type of soil. No clearly defined relation seems to exist between the Mn content and the variety, size or date of harvest of the vegetable. J. J. SKINNER

Potato plants grown in mineral nutrient media. EARL S. JOHNSON. Univ. Maryland. *Soil Science* **26,** 173–6(1928).—Potato plants grown in sand and water cultures with B-deficient solns. did not develop normally. Plants grown in solns. contg. 0.55 p. p. m. B developed normally. J. J. SKINNER

Measurement of suction power in the seedling stage. KONRAD MEYER. Univ. Göttingen. *J. Landw.* **76,** 11–24(1928).—The app. described has proved accurate in suction-force measurements with a large no. of varieties of oats. The results which will be published later with other physiol. investigations show clearly differences in the osmotic values of the individual varieties and coincide throughout with our hitherto existing knowledge about the different water demands of the varieties. As the limit of concn. for oats the following must be considered. In the case of cane sugar 0.55–0.75 vol.-molar solns., for $CaCl_2$ 3.0–4.0%, for KNO_3 and $NaNO_3$ 3.5–4.5% solns. Oats show remarkably low suction powers, a result that agrees completely with the investigations of Merkenschlagers and Klinkowskis. E. F. S.

The determination of chlorophyll by Willstätter's method. K. MAIWALD. Univ. Breslau. *J. Landw.* **76,** 63–9(1928); cf. *C. A.* **22,** 796.—A criticism of Steche's modification of Willstätter's method and a description of the procedure recommended. E. F. SNYDER

The determination of chlorophyll by Willstätters method. THEODOR STECHE. *J. Landw.* **76,** 71–3(1928); cf. *C. A.* **22,** 796.—A reply to Maiwald (cf. preceding abstr.). E. F. SNYDER

Chemical treatments for shortening the rest period of plants. F. E. DENNY. Boyce Thompson Inst., Yonkers, N. Y. *J. Soc. Chem. Ind.* **47,** 239–43T(1928); cf. *C. A.* **22,** 3014, 3194.—D. describes the use of ethylene chlorohydrin and the thiocyanates of Na, K and NH_4 for shortening the rest period of plants. E. F. S.

Differential staining of specialized cells in Begonia with indicators. DEAN H. ROSE AND ANNIE M. HURD-KARRER. Bur. of Plant Ind. *Plant Physiology* **2,** 441–53 (1927).—When freshly cut tissues of leaves, petioles and young stems of *Begonia* were immersed in 0.2% solns. of bromocresol green, H-ion concns. corresponding to at least p_H 1.5 were indicated. This acidity corresponds to that obtained by electrometric

titrations of the *expressed plant juice.* Since chem. changes occur that result in a decrease in the cell acidity of most of the cells when they are exposed to air, the usual method of vital staining by immersion of cut sections in solns. of indicators is not reliable for tissues such as those of *Begonia.* Two physiologically different types of cells are present, as is shown by their different behavior toward bromocresol green and also toward the oxidase reagents benzidine and gum guaiacum. The "specialized" cells contg. CaC_2O_4 do not change color in the acid indicator soln. Oxidase is present in the "specialized" cell but not in the rest of the tissue. The oxidase reactions do not take place when the reagents are added to the *expressed juice,* apparently indicating that in uninjured cells the enzymes are not in contact with the acid sap. W. T.

The effect of boric acid on the growth of tobacco plants in nutrient solutions. T. ROBERT SWANBACK. Mass. Agr. College. *Plant Physiology* **2**, 475-86(1927).—Pot culture expts. with Shive's 3-salt soln. (*C. A.* **15**, 3659) indicated that B is an essential element for the growth of the tobacco plant. Increasing concns. of H_3BO_3 up to 400 p. p. m. caused slight injury. Optimum growth in the above culture soln. was obtained by the addn. of 2 p. p. m. of H_3BO_3. WALTER THOMAS

Notes on apparatus for low temperature respiration studies. J. H. BEAUMONT, J. J. WILLAMAN AND W. A. DELONG. Univ. of Minnesota. *Plant Physiology* **2**, 487-95(1927).—The thermostat, respiration chamber, absorption unit, circulation mechanism and heat-control mechanism of an app. successfully used in studies on respiration of apple twigs in relation to winter hardiness are described in detail with the use of 6 diagrams. WALTER THOMAS

Variation of the water content of leaves in relation to the wilting of plants. RIICHIRO KOKETSU. Kyushu Imp. Univ. *Proc. Imp. Acad.* (*Japan*) **4**, 229-30(1928).—The ratio between the H_2O content at the time of critical wilting and that at full turbidity is probably sp. for a given plant when cultivated in a given soil. C. J. W.

Anthocyanin pigments of morning glory. II. TAKEO KATAOKA. Imp. Expt. Sta., Tokyo. *Proc. Imp. Acad.* (*Japan*) **4**, 389-92(1928); cf. *C. A.* **22**, 1652.—The sugar-free pigment of the morning glory (*Pharbitis nil,* Chois.) is shown to be pelargonidin. C. J. WEST

Ultra-violet absorption spectrum of chlorophyll in alcoholic solution (LEWKOWITSCH) 3.

Vitamin studies. XV. Assimilation of vitamins A and D in presence of mineral oil. R. ADAMS DUTCHER, J. O. ELY AND H. E. HONEYWELL. Penn. State College. *Proc. Soc. Exptl. Biol. Med.* **24**, 953-5(1927); cf. *C. A.* **22**, 255.—Mineral oils possess the property of dissolving vitamin A from food materials and when given internally they deprive the body of this factor. The calcifying potency of cod-liver oil was not appreciably affected by the presence of mineral oil. Rats were used. C. V. B.

Occurrence of deciduomata in rats low in vitamins A and E. K. SCOTT BISHOP AND AGNES FAY MORGAN. Univ. of California. *Proc. Soc. Exptl. Biol. Med.* **25**, 438 (1928).—In 1 rat of a series maintained on A-low diets, multiple deciduomata occurred spontaneously. This rat was never mated. At 5 months of age it was transferred from a diet low in A to one free from A and low in E. Cornification of the vaginal cell content became complete at once and persisted for 15 days when 2 drops of cod-liver oil were given daily, producing a normal vaginal cell content, although no estrus occurred after the cure. Fourteen days later vaginal blood was noted and autopsy was performed. In another series of E-free rats, persistence of the decidual reaction occurred in those showing resorption of embryos before the 10th day of pregnancy, either when A also was low, or when several matings (and reabsorptions) followed each other without rest periods. C. V. B.

Studies on hemoglobin formation in the rat. GEORGE F. CARTLAND AND F. C. KOCH. Univ. of Chicago. *Proc. Soc. Exptl. Biol. Med.* **25**, 447-9(1928).—Wheat gluten is an adequate dietary protein for promoting hemoglobin synthesis in the rat. Casein is not superior to wheat gluten for this purpose. Hemoglobin and tryptophan in the diet are no better utilized than gluten for this purpose. The blood-forming process in the rat is not dependent upon the presence of vitamins A, B or E in the diet. C. V. B.

The effects of synthetic diets on fertility and lactation. E. TSO. *Proc. Soc. Exptl. Biol. Med.* **24**, 465-8(1927).—Eight synthetic diets are given, with a record of the effects of these diets on fertility and lactation in the rat. C. V. B.

Rickets in rats. V. Comparison of effects of irradiated ergosterol and cod-liver

oil. ALFRED T. SHOHL, HELEN B. BENNETT AND KATHARINE L. WEED. Yale University. *Proc. Soc. Exptl. Biol. Med.* **25**, 551–4(1928); cf. *C. A.* **22**, 3685.—Marked cure of rickets in rats is secured in 2 weeks by feeding cod-liver oil or 0.01 mg. daily of irradiated ergosterol. This is shown by histological prepns. of the bones, the analyses of the blood serum for Ca and P and the ash analyses of the bones. The metabolism studies demonstrate that the cure is accomplished without great increase in the retention of Ca or P. **VI. Effect of phosphate added to the diet of non-ricket rats.** *Ibid* 669–71.—Rachitic rats develop tetany and have high P and low Ca in the blood serum when moderate amts. of phosphate are added to the diet. Rats fed with the same diet, plus antirachitic vitamins, show neither tetany nor an alteration in blood Ca and P and their bones yield a normal amt. of ash. (Cf. following abstr.) C. V. B.

Rickets in rats. VII. Metabolism of calcium and phosphorus of rats fed upon non-ricketogenic diets. ALFRED SHOHL, HELEN B. BENNETT AND KATHARINE L. WEED. Yale Univ. *J. Biol. Chem.* **79**, 257–67(1928); cf. preceding abstr.—Expts. have been conducted in which a rickets-producing diet was modified toward normal by the addn. of salts and vitamins, only one alteration being made at a time so that the effect of the deficiency could be estd. stepwise. Improvement occurred in the growth of animals, in the character of the bones, and in retention of Ca and P and this improvement was brought about primarily by the increase in food consumption. The best results were obtained when the diet was supplemented both with cod-liver oil and by irradiation. **IX. p_H of the feces.** ALFRED T. SHOHL AND FRANKLIN C. BING. *Ibid* 269–74.—Alteration in the feces from alk. to acid occurs when rats fed on Zucker's diet are cured of rickets by cod-liver oil. This change, however, does not occur when rats made rachitic on Steenbock's diet are cured by irradiation of the food or by addn. of alk. phosphates. The cure of rickets, therefore, is not necessarily assocd. with an alteration of the p_H of the feces from alk. to acid although the change is of great interest in interpreting the mechanism of the action of cod-liver oil. A. P. LOTHROP

Dietary requirements for fertility and lactation. XVI. Potency of "Vitavose" versus dehydrated yeast in vitamin B. BARNETT SURE. Univ. of Arkansas. *Proc. Soc. Exptl. Biol. Med.* **25**, 603–5(1928); cf. *C. A.* **22**, 2192.—"Vitavose" compared with dehydrated brewer's or baker's yeasts was a complete failure as the only source of vitamin B for lactation. C. V. B.

Histologic effects of a cholesterol-free diet on adult white rats. W. M. BALDWIN. Albany Med. Coll. *Proc. Soc. Exptl. Biol. Med.* **25**, 646–8(1928).—A series of white rats was raised upon a cholesterol-free diet over a period of 3 generations; it was concluded that cholesterol was to a certain extent built up by the rat body. The rats of the third generation were weak, small and undernourishd and died at 11 to 17 weeks of age. At autopsy there was no evidence of inflammation or degeneration in any of the body tissues. The organs were reduced in size by a decrease in size rather than in no. of the cells forming them. The cytoplasm had suffered greater loss in size than the nucleus. A striking variation in the size of the nuclei of the liver cells was observable. The ovaries contained no corpora lutea and the ova were small. The follicular cells suffered a marked reduction in no. In the testis the cells lining the seminiferous tubules were reduced in no. The spermatozoa, spermatids, spermatocytes and column cells of Sertoli were absent, small spermatogonia being present. Interstitial cells were small. Certain cells were absent in the adrenals; others were small. C. V. B.

Vitamin A in relation to growth and to subsequent susceptibility to infection. H. C. SHERMAN AND M. P. BURTIS. Columbia Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 649–50(1928).—The larger the exptl. animal the greater the amt. of vitamin A needed to maintain a given rate of growth. Expts. also show that the level of intake of vitamin A during early life may markedly influence subsequent susceptibility to infection. C. V. B.

Effect of cholesterol exposed to Röntgen rays on rachitic rats. WILHELM STENSTROM, ANNE LOHMANN AND H. T. HILLSTROM. Univ. of Minnesota. *Proc. Soc. Exptl. Biol. Med.* **25**, 817–9(1928).—The Röntgen radiation of a soln. of 0.6% cholesterol in $CHCl_3$ for 1 to 15 hrs. did not induce any antirachitic potency in the cholesterol. C. V. B.

Avitaminosis. Behavior of some blood enzymes in avitaminosis. Antitryptic action of serum in experimental avitaminosis. F. GENTILE. *Arch. fisiol.* **25**, 21–32, 33–42(1927).—In pigeons (with exptl. beriberi diet) and guinea pigs (with diet free from vitamin C) the glucolytic power of the blood is decreased; in hunger the blood glucolysis is greatly increased. The catalase value for guinea pigs (on a scorbutic diet) sinks at first, and then gradually rises to and above the normal. With pigeons fed with polished rice there is a considerable rise in the antitryptic enzyme content, with a fall on the ap-

pearance of symptoms. With guinea pigs there is an increase of tryptic enzyme on scorbutic diet, and a diminution in hunger. B. C. A.

Antirachitic action of irradiated ergosterol. SIM KI AY. *Mededeel. Rikjs-Inst. pharm. therapeut. Onderzoek* **1927**, 128–31; *Chem. Zentr.* **1927**, II, 1587.—Clinical expts. on children 7–24 months old gave favorable results. The control expts. were carried out with cod-liver oil. C. C. DAVIS

Vitamins in our food. G. SCHMICH. *Zentr. Gewerbehyg. Unfallverhüt* **14**, 178–80; *Chem. Zentr.* **1927**, II, 711.—A short discussion of the vitamin content of various foods. C. C. DAVIS

The vitamin content of the root vegetables which are important as food. ARTHUR SCHEUNERT. Univ. Leipzig. *Z. Zuchtungskunde* **2**, No. 5, 14 pp.; *Chem. Zentr.* **1927**, II, 2021.—Beets, turnips and turnip-root cabbage from the 1925 and 1926 harvests were analyzed for their vitamin content. Vitamin A was present only in turnip-root cabbage and in very small content. All 3 vegetables contained vitamin B in small content. Sugar beets contained a higher vitamin B content that that of ordinary beets raised for food. The vitamin C content of beets was very low, but was surprisingly high in turnips and turnip-root cabbage; in fact, the vitamin-C content of these 2 vegetables is comparable with that of oranges, lemons and tomatoes. C. C. DAVIS

Vitamin. HANS MAUTNER. *Wiener klin. Wochschr.* **41**, 1315–9(1928).—A general discussion. D. B. DILL

The green pigment eliminated with the urine by albino rats fed special proteins. A. GALAMINI. *Arch. farmacol. sper.* **45**, 215–7(1928).—When albino rats are fed an exclusive diet of coagulated egg white or dried fish a green pigment appears in the urine after about a month. If EtOH is administered simultaneously the pigment appears much sooner. Addn. of butter or starch to the diet prevents the pigment formation. The pigment is excreted as a chromogen which rapidly oxidizes in contact with the air to a green substance. If the urine is covered with PhMe the color gradually disappears but returns when air is admitted. The color gradually disappears in the presence of acid but reappears when the acid is neutralized. Tests for bile pigments were negative. Exclusive diets of meat or cheese failed to cause pigment formation even when EtOH was administered. A. W. DOX

Determination of the antiscorbutic value of foodstuffs by Höjer's method. MARIANNE GOETTSCH. *J. Pharm. Soc.* **1**, 168–77(1928).—The presence of scurvy in guinea pigs may be detected by histological changes in the incisor root. By Höjer's method of assay of the antiscorbutic potency of a substance, it is possible to det. the min. protective dose of that substance; but such variations occur within a group of animals on any one inadequate level of orange juice, that the value of an inadequate dose cannot be detd. without the use of great numbers of animals. By this method special feeding need be carried on for only 2 weeks instead of 8 as in the other method; hence, there is less danger of animals dying from causes other than scurvy in the course of the test. Less than 2 weeks is required for the prepn. of the teeth for microscopical study, so that information as to the antiscorbutic value of a foodstuff may be obtained in about 4 weeks' time. In an appendix to this article, Kathleen M. Key has given details of the technic of the Höjer method. W. O. E.

Some properties of ergosterol. FRANK WOKES AND STANLEY GORDON WILLIMOTT. Univ. Liverpool and Biochem. Lab. Cambridge. *J. Pharm. Soc.* **1**, 188–93(1928).—Ergosterol prepd. from yeast gives with $SbCl_3$ blue colors very like the "vitamin" colors given by the same reagent on cod-liver oil. Quant. estn. of these colors by means of the Lovibond tintometer showed the intensity of initial blue color produced under standard conditions to run roughly parallel with the concn. of ergosterol. Feeding expts. on the ergosterol failed to reveal the presence of vitamin A. Spectroscopic examn. of the colors has given evidence of a difference in the characteristic absorption bands in the ergosterol blue as compared with the "vitamin" blue. Examn. of samples of ergosterol contg. different amts. of zymosterol indicates that the blue color is not due to the latter sterol, which is now known to be present in all samples of ergosterol prepd. from yeast fat. W. O. E.

Trypsin secretion of infants. T. LUKACS. *Am. J. Diseases Children* **31**, 235–40 (1926); *Physiol. Abstracts* **11**, 218.—It has been shown previously that pancreatic amylase and lipase are increased in rickets. L. investigated the trypsin content of the stools of 231 infants by the Gross-Fuld method, and found that in all cases of infectious disease the trypsin was decreased, but that in rickets it was increased. He suggests that the reabsorbed trypsin may produce some degree of protein poisoning which may be the cause of some of the symptoms of rickets. H. G.

Insulin in malnutrition. L. Fischer and J. L. Rogatz. *Am. J. Diseases Children* **31,** 363–72(1926).—From observations on 27 malnourished infants the authors conclude that insulin treatment is effective in cases showing anemia, apathy and loss of weight. H. G.

Acidified milks. H. K. Faber. *Am. J. Diseases Children* **31,** 395–409(1926); *Physiol. Abstracts* **11,** 220.—A consideration of the effects of acid feeding on enzyme action and metabolism shows that acidified milk may be a useful therapeutic agent for certain sp. disorders, but should be given only when there are sp. indications and for periods of time limited by the regression of symptoms. The routine use of sour milk in feeding normal infants is not to be encouraged. H. G.

Metabolism of under-nourished children. III. Urinary nitrogen, with special reference to creatinine. C. C. Wang, M. Frank, R. Kern and B. B. Hays. *Am. J. Diseases Children* **32,** 360–6(1926); *Physiol. Abstracts* **12,** 48.—Creatinine N increased with increasing body weight and with age; creatine occurred in all the 26 children examd. NH_3 and total N were fairly const. The creatinine coeff. ranged from 5.5 to 9.5, and the creatinine excretion for the same child remained very const. H. G.

Calcium metabolism studies. W. A. Price. *Am. J. Diseases Children* **33,** 78–95 (1927); *Physiol. Abstracts* **13,** 93–4.—Expts. with chicks show that cod-liver oil and cholesterol are both changed by sunshine, over-exposure causing deleterious effects; the administration of irradiated cod-liver oil by rubbing it on the neck increases the C content of the blood and of the local tissue fluid. The effect may be related directly to the utilization of the Ca from the food, or to the Ca soly. Dental caries is directly influenced by the administration of activators of Ca metabolism. H G

Studies on experimental rickets. XXVIII. Does vitamin D pass into the milk? E. V. McCollum, N. Simmonds, J. E. Becker, and P. G. Shipley. *Am. J. Diseases Children* **33,** 230–43(1927); *Expt. Sta. Record* **56,** 796–7.—To det. whether it is possible for nursing women to increase the vitamin D content of their milk by taking cod-liver oil and, if so, when the treatment should begin and how long it should be continued, a series of feeding expts. in continuation of the studies previously noted (*C. A.* **21,** 118) was conducted upon female rats, with the addn. of suitable amts. of cod-liver oil to a basal diet supposedly adequate in all respects except for a deficiency in vitamins A and D. A parallel series of expts. was run with butterfat in place of cod-liver oil for the purpose of detg. whether a diet complete in every respect except vitamin D is capable of producing milk with protective value against rickets. The entire time covered in any one expt. extended from about a month before mating until the young were eating the mother's diet, but the individual periods were varied to cover one or all of the periods before mating and during pregnancy and during lactation before and after the young eat of the mother's food. When the rats were fed cod-liver oil before mating, during pregnancy and during the first 2 weeks of nursing, considerable protection against rickets in the young was afforded, but not as much as when the young were continued on the cod-liver oil ration. When the cod-liver oil was fed only during the first weeks of the nursing period, there was very little protection against rickets. No protection was afforded by the butterfat diet. These expts. are thought to demonstrate that the vitamin D of cod-liver oil does pass into the mother's milk, but that to insure a considerable amt. of this vitamin the diet should be supplemented by cod-liver oil during pregnancy as well as lactation. H. G.

Inorganic blood phosphate. E. M. Koch and M. H. Cahan. *Am. J. Diseases Children* **34,** 187–97(1927); *Physiol. Abstracts* **13,** 80; cf. *C. A.* **21,** 2149.—Growing and mature rats were fed on McCollum's rachitic diet and the inorg. blood phosphate was detd. by Brigg's modification of the Bell-Doisy method; in both groups the phosphate was lowered. Irradiation raised the phosphate value for mature rats, but not for the young ones, while the addn. of cod-liver oil to the rachitic diet raised the phosphate in both. The addn. of irradiated cholesterol prevented the development of rickets and caused a concn. of phosphate; non-irradiated cholesterol had no effect as a preventive of rickets, but tended to bring the phosphate up to normal in both young and mature rats. Thus cod-liver oil, direct irradiation, and feeding with irradiated cholesterol all raise the blood phosphate almost to normal, and it is possible to have a low phosphate value and low product of Ca and P with apparently perfect bone calcification. H. G.

Antirachitic properties of irradiated dry milk. G. C. Supplee and O. D. Dow. *Am. J. Diseases Children* **34,** 364–71(1927); *Physiol. Abstracts* **13,** 94; cf. *C. A.* **21,** 3071; **22,** 104.—Expts. carried out with rats show that irradiation of dried milk with ultra-violet rays increases its nutritive and therapeutic properties, provided that over-exposure to rays of short-wave length is avoided. No measurable destruction of the

easily oxidized vitamins A and C occurs in the process, and there is no production of disagreeable taste or odor such as occurs with ordinary milk products. H. G.

Gastric digestion. The relation of the hydrogen-ion concentration, volume and buffer capacity of the gastric contents to a milk test meal. R. B. MILES AND A. T. SHOHL. *Am. J. Diseases Children* **34**, 429–42(1927); *Physiol. Abstracts* **13**, 91.—Careful observations made on 2 female infants (6 months old and 8 months) show that meals combining small vol. and low concn. of buffer substances are the most easily digested; such meals require only a relatively small quantity of acid gastric juice to bring them to the p_H optimal for digestion. The effects of varying the relative values of the 3 factors are discussed. H. G.

The food values of New Zealand fish. VII. The vitamin content of the tarakihi (Chilodactylus macropterus). J. MALCOLM. *Trans. Proc. New Zealand Inst.* **57**, 879–80(1926); *Physiol. Abstracts* **13**, 95; cf. *C. A.* **21**, 3990.—The flesh of the parboiled fish, contg. an av. of 20% protein and 6% fat, was made up in 100 g. packets and kept in cold storage. Other quantities were dried. With protein as a criterion of the amt. of fish used, fish diets were made with the proximate principles always in the same proportions as in the basal diet, but with 5, 10, 15 or 20% (all) of the casein replaced by fish protein, allowance being made for the accompanying fat, extractives, etc. With the frozen material the rats grew up to 100 g. in one litter at the 5% fish-protein level but in general 15% was necessary. Less marked but still good results were obtained with dried fish. (Vitamin D was not distinguished from vitamin A in these expts.) H. G.

Studies on artificial feeding of infants. T. SUZUKI. Kyoto Imp. Univ. *Oriental J. Diseases of Infants* **2**, 1–10(1927); *Bull. Hyg.* **3**, 579(1928).—Rats developed better on dried than dextri-malted milks. A repetition on a group of children gave the same results. GEORGE R. GREENBANK

General inhibition of growth by an experimental change in the carbohydrate catabolism. HERBERT HENTSCHEL. *Klin. Wochschr.* **7**, 1086–8(1928).—Young rats remain quite well, but do not grow, in an atm. of 95.5% O and 4.5% CO_2. The lactic acid content of such rats is less than half that of rats that have been raised in air. The high O content prevents glucolysis with formation of lactic acid; and lactic acid is essential for cell growth. MILTON HANKE

Formation of antirachitic vitamin in the absence of light. A. SCHITTENHELM AND B. EISLER. *Klin. Wochschr.* **7**, 1118–9(1928).—Barley does not contain vitamin D. Barley that has been allowed to germinate in the dark contains vitamin D. Ergosterol could not be demonstrated. Provitamin D was not present. M. H.

Beneficial results in vitamin therapy with the health nutrient "Alentina." The theoretical foundation for the use of Alentina. A. SCHITTENHELM. Med. Clinic, Kiel. *Klin. Wochschr.* **7**, 1214–20(1928).—The early germination of barley, or of other cereals, leads to the formation of root processes that contain vitamins A, B, D and E. These processes can be dried and powd. without injuring the vitamin. The powder contains about 30% of N-contg. substances and has a low fat content. A powd. yeast can be prepd. (process not given) that is odorless, has a pleasant taste and contains, besides vitamins, 60% of protein and 7% of inorganic constituents rich in P. Alentina is a mixt. of the above 2 powders with nutrient malt flour and flavoring materials. Case reports are given to show the beneficial action of Alentina. MILTON HANKE

The vitamin content of the nutrient preparation, "Promonta." H. STEUDEL AND P. N. SCHÜRHOFF. *Klin. Wochschr.* **7**, 1605(1928); cf. L. Bitter and F. Weigmaun, *Klin. Wochschr.* **7**, 1329–30(1918).—Promonta is a valuable vitamin-contg. prepn. It does not contain vitamin C, which is not surprising in a dried product. It is unusually free from bacteria; 0.1 g. contains only about 10 bacteria. The dose used by B. and W. was too small (0.5 g.). The comm. 2 g. tablets are recommended. MILTON HANKE

Vitamin D in adults. Its effect on the calcium and inorganic phosphate of the blood. R. E. HARVARD AND J. C. HOYLE. Biochem. Lab., Cambridge. *Biochem. J.* **22**, 713–6(1928).—Adding 8 mg. per day of irradiated ergosterol to the diet of a healthy adult for 21 days during the winter showed no change in the blood inorg. phosphate or serum Ca. No better results were obtained by irradiation with C arc lamps for a period of 16 days during the winter. BENJAMIN HARROW

Specificity of ergosterol as parent substance of vitamin D. OTTO ROSENHEIM AND THOMAS ARTHUR WEBSTER. National Institute for Medical Research, Hampstead, London. *Biochem. J.* **22**, 762–6(1928).—See *C. A.* **22**, 3200. BENJAMIN HARROW

Antiscorbutic fraction of lemon juice. VII. SYLVESTER S. ZILVA. Lister Inst., London. *Biochem. J.* **22**, 779–85(1928); cf. *C. A.* **21**, 3072.—Phenolindophenol (*B*) added to decitrated lemon juice (*A*) until the indicator is no longer reduced and adjust-

ing the p_H to 7 destroys the antiscorbutic activity (*C*) in 24 hrs. Purified antiscorbutic fractions lose their activity more rapidly than (*A*). (*A*) dialyzed in collodion thimbles of a permeability which leaves the soln. inactive after 3 days loses the capacity for reducing (*B*). The reducing capacity is largely retained by the juice when dialyzed in thimbles of a permeability which yields an active juice at the end. Acidity retards the deterioration of (*C*). Autoclaving at 40 lb. pressure (143°) for 1 hr. under anaerobic conditions causes little loss in the activity of (*A*). BENJAMIN HARROW

Dual nature of water-soluble vitamin B. II. The effect upon young rats of vitamin B_2 deficiency and a method for the biological assay of vitamin B_2. HARRIET CHICK AND MARGARET HONORA ROSCOE. Lister Institute, London. *Biochem. J.* **22,** 790-9 (1928); cf. *C. A.* **21,** 3073.—Vitamin B_1 is the antineuritic factor and is less heat-stable; vitamin B_2 is the more heat-stable modification. In the absence of vitamin B_2 the animal fails to grow. Vitamin B_2 is present in pptd caseinogen and can be removed by thorough extn. with water acid and acid alc. As a source of vitamin B_1 the antineuritic concentrate of Kinnersley and Peters (*C. A.* **20,** 436; **22,** 447) is used. B. H.

Studies on color tests for sterols and vitamin A. I. Sterol tests. FRANK WOKES. Univ. of Liverpool. *Biochem. J.* **22,** 830-5(1928). Pure cholesterol (1), freed from ergosterol, gives with the "vitamin" reagents (concd H_2SO_4, $AsCl_3$, $SbCl_3$) (*A*) red colors persisting for many hrs. Similar results are obtained with cholesteryl acetate (2) and chloride (3), α-cholesterylene (4), cholestene (5), and Ψ-cholestene (6). (1), (2), (3), (5) and (6) in $CHCl_3$ soln., left in contact with concd. H_2SO_4 for some hrs., and then dild. with more $CHCl_3$, gives a purple or violet color. No colors are produced by CH_2O alone and $CHCl_3$ solns. of (1) or its derivs. which have not been in contact with concd. H_2SO_4. Irradiation of sterol derivs. generally has the effect of rendering the colors more transient. Activation with Ac_2O, Bz_2O_2, or CH_2O may lead to blue or purple color when (*A*) is added; cholestenone, which has been suggested as a typical product of irradiation, gives transient red colors with (*A*) and negative results with all other tests. $SbCl_5$ gives the color sequence red—blue—red with all cholesterol derivs. except the oxidation products with ordinary concns. of ergosterol. (*A*) gives the usual red, but at higher concns., the red changes to purple or blue. Sitosterol gives results similar to those with cholesterol, but more slowly. BENJAMIN HARROW

Effect of inanition and vitamin B deficiency on the adrenal glands of the pigeon. GUY F. MARRIAN Univ. College, London. *Biochem J.* **22,** 836-44(1928).—The results obtained by Marrian, etc (*C. A.* **22,** 1178) showing that adrenal hypertrophy occurred in starving pigeons receiving vitamin B and also in pigeons forcibly fed on an artificial vitamin B-free diet have been confirmed. The hypertrophy in the vitamin-deficient pigeons appears to be due to a deficiency in vitamin B_1. B. H

The metabolism of fats in infancy. PHILIP S. POTTER. *Arch. Pediatrics* **45,** 483-90(1928).—A review with bibliography. JOSEPH S. HEPBURN

Experiences with banana feeding in infants. L. VON MEYSENBUG. *Arch. Pediatrics* **45,** 509-13(1928).—Thoroughly ripe and macerated banana may be fed as early as the 4th month. It is curative in scurvy, may stimulate the appetite, and is of especial value in nephritis since it contains only approx. 0.4% protein. JOSEPH S. HEPBURN

The metabolism of carbohydrates in infancy. PHILIP S. POTTER. *Arch. Pediatrics* **45,** 514-25(1928).—A review with bibliography. Sections are devoted to absorption, blood sugar, N retention, lactose, sucrose, maltose and starch. J. S. H.

Maintenance and production requirements of ewes and lambs. T. B. WOOD AND W. S. MANSFIELD. *J. Ministry Agr.* **35,** 211-9(1928). E. H.

Absorption of ingested proteins in human beings. The absorption of unaltered fish proteins in adults. MATTHEW BRUNNER AND MATTHEW WALZER. Jewish Hospital, Brooklyn, N. Y. *Arch. Internal Medicine* **42,** 172-9(1928); cf. Walzer, *J. Immunol.* **14,** 143(1927); *Am. J. Med. Sci.* **173,** 279(1927); *Arch. Dermatol. Syphilis* **17,** 659(1928).—Out of 65 persons 15-70 years old 93.8% showed absorption of unaltered fish protein from the digestive tract. The wheal appeared within 15 min. in 50% and within 30 min. in 83.3% of the subjects. The reaction is delayed or prevented in atopic patients or members of certain atopic families, further, if the herring had been baked or cooked or taken on a full stomach The reaction is materially hastened by 3.9-7.8 g. $NaHCO_3$ before the fish ingestion. Hand and forearm are less sensitive than arm and thigh. The negative reaction in a patient with hookworm disease was caused by true impermeability of the entire alimentary tract to egg and fish albumin. M. J.

Irradiated ergosterol in the therapy of rickets. G. GENOESE AND A. ZALLOCCO. *Pediatria Rivista* **36,** 917-24(1928).—Expts. with 20 rachitic children 6-18 months old showed that the effect of irradiated ergosterol in rickets is slow and far behind that claimed by German authors. It has no advantage over direct ultra-violet treatment

or Zuke's cod-liver oil ext. A strikingly rapid improvement and complete recovery in 4 weeks were effected by a combination of irradiated ergosterol and *thyroid*. A review of the literature is included. MARY JACOBSEN

The vitamin content of olive oil irradiated with ultra-violet rays. GUIDO RIGOBELLO. *Rev. sud-americana endocrinol. immunol. quimioterap.* **11**, 456–66(1928). (In Italian.)—Rats were kept on McCollum's diet 3143 or a modified diet of the Ist. Biochim. Italiano with the addn. of orange juice, brewer's yeast and 5% olive oil irradiated by a Hanau Hg lamp at a distance of 40 cm. in a 5-mm. layer during 35–40 min. Excess irradiation destroys the protective power. The fluorescence of the oil is not affected by the irradiation. The bone calcification of rats receiving irradiated oil was almost normal and 25% higher than that of the controls. Very young rats also show an increase of bone growth, which, however, differs from normal (Röntgen). There is a general increase in wt. Severe cases of avitaminosis are improved and death is prevented. In view of the complicated picture and partly unknown course of human rickets it would not be correct to call the effect antirachitic. MARY JACOBSEN

Urobilinogen and urobilin excretion in the stool after fat and lean foods. HUGO SALOMON. *Arch. Verdauungskrankh.* **42**, 572–4, 575–8(1928); cf. *C. A.* **21**, 1295.—S. reports an increase in urobilinogen and urobilin excretion due to a fat-rich diet. There is also an increase of urobilinogen and urobilin excretion in the stool after "schlackenreiche" foods. FRANCES KRASNOW

The single test-breakfast investigation as the best method for the clinical test of gastric function. JACOB KAUFMAN. *Arch. Verdauungskrankh.* **43**, 230–43(1928). FRANCES KRASNOW

Diet in heart and kidney diseases. J. R. DARMALL. *J. Philippine Islands Med. Assoc.* **8**, 50–2(1928).—Discussion. FRANCES KRASNOW

The nature of the anestrous condition resulting from vitamin B deficiency. A. S. PARKES. Univ. Coll., London. *Quart. J. Exptl. Physiol.* **18**, 397–401(1928).—A deficiency in vitamin B represented by 1% or less of yeast ext. added to a basal diet brings about an abrupt cessation of the estrous cycle in rats in about 4 weeks. The anestrus so produced, which begins just before the characteristic decline in wt. appears, applies both to ovarian and extra-ovarian phenomena of estrus, and is terminated at any time up to 2 months later by death. Injection of estrin (10 m. u.) during the anestrous state results in the induction of estrous symptoms in the accessory organs. The anestrus due to this deficiency results not from inability of the animal to respond to the estrus-producing stimulus but from failure to produce estrin. FRANCES KRASNOW

Effect of diets deficient in vitamin A or B on resistance to paratyphoid-enteritidis organisms. ELIZABETH VERDER. Univ. of Chicago. *J. Infectious Diseases* **42**, 589–604(1928).—Deficiency in vitamin B of the diets of rats does not render the intestinal tract permeable to *B. enteritidis* but it does seem to raise the level at which the organisms live and multiply in the intestinal tract. *B. enteritidis* fed to rats on diets deficient in vitamin A (also deficient in vitamins D and E) was isolated from the spleen of these animals and found in the intestinal tract at higher levels than normally. J. H. L.

A comparison of the Bergeim and standard methods of determining coefficients of utilization with suggested modifications. V. G. HELLER, C. H. BREEDLOVE AND W. LIKELY. Okla. Agr. and Mech. Coll. *J. Biol. Chem.* **79**, 275–82(1928).—Standard utilization methods are of value only in limited studies as they are very time-consuming and accurate only within limits. The Bergeim method (*C. A.* **20**, 3718) gives results comparable to the older methods but usually some of the added Fe is not recovered and sampling of any portion of the feces at random does not give uniform samples as it is exceedingly doubtful whether the Fe_2O_3 is eliminated in like proportion in all parts of the feces. Most rations contain sufficient Fe to make addn. unnecessary and such a procedure provides a more uniform intake and a more evenly distributed Fe excretion in feces. The suggested detn. of the coeffs. of utilization is as follows: A uniform mixt. of the food to be studied is fed for 2 weeks prior to the time of analysis and samples of feces are collected daily over a considerable period of time and are rapidly dried and preserved. One g. samples of feed and 0.5 g. samples of feces are analyzed for Fe. The other constituents of feed and feces are detd. by the customary methods and the coeffs. of utilization calcd. as suggested by Bergeim. A. P. LOTHROP

A comparison of raw, pasteurized, evaporated and dried milks as sources of calcium and phosphorus for the human subject. MARTHA M. KRAMER, ESTHER LATZKE AND MARY M. SHAW. Kansas Agr. Expt. Sta. *J. Biol. Chem.* **79**, 283–95(1928).—The child retains more Ca when it is supplied in fresh milk than when it is furnished in equiv. amts. of dried milk. The 5 children were not given evapd. or pasteurized milks. In adults more favorable Ca balances were obtained with fresh and evapd. milks than

with pasteurized and dried milks. The results with evapd. milk were at least as good as with fresh milk. Milk from cows kept in the barn was not as satisfactory as that from cows on pasture. In general the P balances followed the trend of the Ca figures.
A. P. Lothrop

The mechanism of epinephrine action. I. The influence of epinephrine on the carbohydrate metabolism of fasting rats, with a note on new formation of carbohydrates. Carl F. Cori and Gerty T. Cori. State Inst. for the Study of Malignant Disease, Buffalo, N. Y. *J. Biol. Chem.* 79, 309-19(1928).—In fasting rats performing muscular work there is a diminution of only 22 mg. of glycogen between the 24th and 48th hr. of fasting. This constancy of glycogen content is probably due to the new formation of glycogen from non-carbohydrate material as fast as it is used up. It is suggested that the term "gluconeogenesis" should be reserved for cases where the sugar formed from non-carbohydrate sources becomes stabilized and should not be used for carbohydrate formation from protein or fat as an intermediary step in the complete oxidation of these mols. Injection of epinephrine does not change the respiratory quotient of 0.715 in 24 hr. fasting rats although there was an av. increase in heat production of 17.3% with a corresponding increase in O_2 consumption. Three hrs. after the injection of 0.02 mg. per 100 g. of body wt., there was an av. diminution of 57 mg. of body glycogen, mainly from muscle, which was accompanied by an increase in liver glycogen of 36 mg. The muscle glycogen is probably converted into liver glycogen with lactic acid as an intermediary stage as oral administration of lactic acid resulted in the formation of considerable amts. of liver glycogen. Muscle glycogen, therefore, is an indirect source of blood sugar if the liver is present and if there is escape of lactic acid from the muscles. Thus epinephrine influences the carbohydrate metabolism of the peripheral tissues since it leads to the disappearance of muscle glycogen. **II. The influence of epinephrine and insulin on the carbohydrate metabolism of rats in the postabsorptive state.** *Ibid* 321–41.—"After non-glucosuric doses the most prominent effect of epinephrine is observed in the peripheral tissues and consists in a mobilization of muscle glycogen and in a decreased utilization of blood sugar. Oxidation of muscle glycogen is increased under postabsorptive conditions, sharply distinguishing the action of epinephrine from the effects of pancreatectomy. Part of the lactic acid arising from the breakdown of muscle glycogen escapes removal by oxidation and is carried to the liver where it is deposited as glycogen. In this way a cycle of carbohydrates is established. Blood sugar derived from liver glycogen is utilized in the muscles and lactic acid derived from muscle glycogen is returned to the liver. Epinephrine hyperglucemia develops because the utilization of blood sugar is diminished in relation to the supply of blood sugar by the liver, even if the supply is not much higher than normal. Insulin is the hormone that leads to a preferential utilization of blood sugar and indirectly of liver glycogen. The antagonistic action between insulin and epinephrine is explained by their divergent effect on blood sugar utilization." This extrahepatic action of epinephrine has not been emphasized before. **III. The influence of epinephrine on the utilization of absorbed glucose.** *Ibid* 343–55.—When glucose is fed to 24 hr. fasting rats and 0.02 mg. of epinephrine per 100 g. of body wt. is injected subcutaneously in 0.1 cc. of fluid, hyperglucemia and glucosuria occur after 1 hr. and persist for 4 hrs. and the glucose excretion remains practically const. from hr. to hr. There is a diminished absorption of glucose from the intestine. The injected rats deposit more liver glycogen than the controls after the 1st hr. In the 4 hr. absorption period the rats injected with epinephrine deposit 10 parts less body glycogen and oxidize 5 parts less sugar (per 100 parts of absorbed sugar) than the controls. Of the 15 parts which fail to be utilized in the peripheral tissues 5 parts are stored in excess in the liver, 6 are excreted in the urine and 3 are retained in the body fluids. The glucosuria which develops during the period of increased glycogen deposition in the liver results from a decreased utilization of blood sugar in the peripheral tissues. The extra heat (16.4%) produced during glucose absorption by rats receiving epinephrine is furnished exclusively by fat oxidation. The data so far available do not, however, warrant the conclusion that there exists a direct relationship between epinephrine and fat metabolism.
A. P. Lothrop

The vitamin of fertility—experimental studies on the sexual glands and on the endocrine system during avitaminosis. Vincenzo Bisceglie. *Arch. sci. biol.* (Italy) 11, 194–211(1928).—White rats were divided into 2 groups of ten. The first received the basal diet No. 199 (starch 67, casein 18, pork 8, cod-liver oil 2, vitamin B 1, salts 4%). The second group received the same basal diet to which was added 2 drops per day of wheat oil, or 0.4 g. per day of ground wheat. The expts. continued for 6 months. Pathol. changes were detd. by histological methods (Ciaccio's for the lipoids; Van Gieseon's for connective tissue; Pianese's for granular secretion; Fe hematoxylin for spermato-

genesis; and Wiesel's for the medulla of the suprarenals). *Conclusion.* (1) Basal diet 199 administered to rats produced in the male and female sexual glands degenerative changes resulting in complete sterility. (2) If oil of wheat 2 drops per day was added to diet 199 the degenerative changes were prevented and fertility remained normal. (3) Glands of internal secretion of rats fed with diet 199 showed hyperplasia and hypertrophy but these changes were lacking when oil of wheat was added to the diet. These modifications were probably the result of the changes of the sexual glands than the direct action of the avitaminosis diet. PETER MASUCCI

Antirachitic and growth-promoting action in rats of blood sterols and steryl phosphate. HANS V. EULER, BETH V. EULER AND MARGARETA RYDBOM. *Acta Med. Scand.* **68**, 371–84(1928).—Sterols extd. from dried red blood cells when added to a diet free from vitamin A and D cause great stimulation of growth and prevent the occurrence of rickets if the material had been radiated with ultra-violet rays. It is not effective without radiation. The min. effective dose is 0.05 mg. per day and per rat. Steryl phosphate and phosphite esters were also found very effective in preventing rickets after radiation, causing also a strong, uniform and persistent increase in wt. Pure cholesteryl acetate cannot be activated by ultra-violet rays and contrary results are explained as being due to the presence of the provitamin D as impurity in the prepn. of other authors. S. MORGULIS

Studies on the biochemistry of avitaminosis. VII. Influence of experimental scurvy on hippuric acid synthesis. ALEXANDER PALLADIN AND D. ZUVERKALOV. *Biochem. Z.* **195**, 8–13(1928).—Expts. on the ability of animals sick with scurvy to synthesize hippuric acid show that this becomes reduced in the majority of guinea pigs depending upon the severity of the disease, and a much smaller percent of injected BzOH is excreted as hippuric than normally. In all sick animals the excretion of hippuric acid is diminished even at a time when the animals still consume the usual amt. of food. S. MORGULIS

Changes in metabolism through radiation. III. Changes in carbohydrate metabolism. LUDWIG PINCUSSEN AND DOROTHEE JACOBY. Stadtisches Krankenhaus am Urban, Berlin. *Biochem. Z.* **195**, 449–56(1928).—The blood lactic acid diminishes 20–30% under the influence of radiation. S. MORGULIS

The phosphatide content of organs following feeding of large quantities of phosphatides. BRUNO REWALD. *Biochem. Z.* **198**, 103–11(1928).—About 90% of the phosphatide fed in large amts. and over long periods of time is absorbed through the gastrointestinal canal. Following continued feeding over several months there is definite accumulation of phosphatide in such important organs as the brain, kidney or liver. The blood shows a considerable increase in the phosphatide content of the ether-alc. ext. Also the fat-rich organs and the adipose tissue have a greatly increased phosphatide content. Even large quantities of phosphatide fed to animals have no effect on their health condition. S. MORGULIS

Nitrogen balance and the carbon-nitrogen ratio of the urine in experimental scurvy uncomplicated by hunger. NATALEI YARUSOVA. Inst. for Nutritional Physiology, Moscow. *Biochem. Z.* **198**, 128–37(1928).—During the development of scurvy in animals fed artificially with enough food to prevent the occurrence of complicating starvation effects, the N balance changes from pos. to neg. The utilization of N of the food is not as good as normally, and the small variations in the N excretion do not indicate that there is really an increased destruction of protein. The urinary C increases, so that the C:N ratio, in spite of the almost const. N, also rises. S. M.

Nitrogen metabolism in one-sided nutrition. II. Nitrogen metabolism of chickens during B-avitaminosis. B. A. LAVROV AND S. N. MATZKO. Inst. for Nutritional Physiology, Moscow. *Biochem. Z.* **198**, 138–48(1928).—The complication of B-avitaminosis in chickens by starvation has been prevented. Under such exptl. conditions the wt. of the birds does not change much even when the symptoms of the B-avitaminosis are fully developed. The utilization of the food N remains satisfactory, but there is nevertheless a neg. N balance and an increased uric acid excretion which shows that in the initial stages of the avitaminosis there is already an intense destruction of nitrogenous materials. S. MORGULIS

Fat metabolism following splenectomy. S. LEITES. Inst. of Medicine, Charkow. *Biochem. Z.* **198**, 157–62(1928).—Following splenectomy the hydrolysis of fat, probably in the liver, is disturbed; this is in part at least responsible for the increased alimentary lipemia. The process of hydrolysis of neutral fat is partly transferred to the lungs in splenectomized dogs. The "acetone body" disappearance is slower in splenectomized animals, acetonemia resulting from loading with fat in the diet. This acetonemia is not relieved by the simultaneous administration of glucose. The administration of

glucose increases the hypercholesterinemia observed in expts. with excess fat in the food. These phenomena appear definitely 4–5 hrs. after overfeeding with fat in animals which had been splenectomized one month. S. MORGULIS

Studies on the need and the available amount of fat-soluble vitamins for children in the public schools of Malmö. ERIK M. P. WIDMARK AND BERTEL SVENSSON. Med. Chem. Inst., Lund. *Skand. Arch. Physiol.* **54**, 127–44(1928).—A study of the growth in wt. and length, hemoglobin, incidence of night blindness among control groups of school children (7 to 14 years of age) and those receiving 15 g. cod-liver oil weekly indicates that the children of the public schools in Malmö suffer from no lack of fat-sol. vitamins. The only difference between the 2 groups was the lesser frequency of sickness in the cod-liver group. S. MORGULIS

The effect of mode of loading on the metabolism. P. O. KLINGENDAHL AND NIILO PESONEN. Univ. Helsingfors. *Skand. Arch. Physiol.* **54**, 169–74(1928).—The load causes an increase in metabolism of 90.6–136.6% when carried in both hands or of 179.9–247.6% when carried in one hand as compared to the metabolism with the same load carried on the back. S. MORGULIS

Contribution to the study of the metabolism of carbon in the course of avitaminosis B. T. J. TUBOBINSKI. Dr. Pharm. *Thesis*, Paris **1928**, *Bull. soc. hyg. aliment.* **16**, 270–1(1928).—The C ingested and excreted by pigeons receiving a natural diet composed of grain, on the one hand, and a synthetic diet contg. no vitamin B, on the other, was detd. micro-analytically by Desgrez' method, adapted and modified to permit of the titration of C alkalimetrically. The total amt. of C ingested per bird was approx. the same for both groups (9.06 and 8.90 g. per day, resp.); but those fed a normal diet excreted about 30% in non-gaseous form, and the others only 18–20%. The amt. of C excreted daily was: for the normal birds, 2.5 g. in the feces and 0.22 g. in the urine; for those given the synthetic diet, 1.6 and 0.16 g. daily for the 1st–6th day; 1.18 and 0.23 for the 7th–12th day, 1.32 and 0.40 g., resp., for the 13th–17th day. It would therefore appear that, at least during the early stages of avitaminosis B, there is a more complete assimilation of the ingested food due to a defensive reaction of the organism. The increase in the amt. of urinary C seems to prove that the amt. of incompletely oxidized C increases in exptl. avitaminosis B, and that consequently (as previously observed by Randoin and Simonnet) vitamin B plays a part in the disintegration of C-contg. substances, probably carbohydrates. A. PAPINEAU-COUTURE

The research laboratory and cattle feeding experiment station of the Sociéte scientifique d'hygiène alimentaire. J. ALQUIER. *Bull. soc. hyg. aliment.* **16**, 283–326 (1928); cf. *C. A.* **22**, 803.—A discussion of the economic value and social importance of animal production, with an outline of the general program for the improvement and intensification of animal production in France, a description of the expt. station of the Soc. sci. hyg. aliment. at Rue du Ruisseau, Paris, and an outline of the work carried out at this station in 1925–27. A. PAPINEAU-COUTURE

The rational use of certain saccharine substances in dietetics. (MRS.) L. RANDOIN AND R. LECOQ. *Bull. soc. thérap.* [8] **32**, 293(1927); *Bull. soc. hyg. aliment.* **16**, 246–7 (1928).—R. and Simonnet (*C. A.* **22**, 3673) previously showed that when a considerable proportion of saccharine substances is added to the diet, it is necessary to add a certain amt. of vitamin B to prevent digestive and nervous troubles. Expts. carried out with ordinary commercial sucrose and lactose behaved in practically the same way as the carefully purified products previously used. Addn. of Soxhlet's sugar (dextrin obtained by inversion of potato starch with malt) to the ration of pigeons causes polyneuritis, death taking place on the 25th–35th day; but the addn. of dry malt ext. (contg. chiefly maltose) instead of dextrin to the ration assures normal development, showing that maltose contains vitamin B, but not dextrin. The high nutritive value of dry malt ext. is shown by the fact that when added to substances having no nutritive value (*e. g.*, filter paper or agar-agar) it can sustain life for a long time; but when used alone and in absence of inert substances death takes place in 30–35 days. A. PAPINEAU-COUTURE

Biochemical investigation on starvation. G. MOURIQUAND, A. LEULIER, A. SIMÉON AND A. FINCK. *Paris-médical* **18**, 406(1928); *Bull. soc. hyg. aliment.* **16**, 331 (1928).—As already known, total fast causes a considerable decrease in the glycogenic reserves of the liver, while at the same time the glucemia remains const. and the ketogenesis increases. These facts have been entirely confirmed in starving guinea pigs. The glucose of the blood seems to have lost all ketolytic action, which remains a property of hepatic glycogen as soon as it has reached a certain value. The ingestion of sufficient carbohydrates enables the liver again to muster dynamic glycogen which can prevent acidosis. The results obtained by M. *et al.* also show that guinea pigs which are given nothing but water do not eliminate more NH_3 than normally fed animals, and

that the ratio of N titratable with CH_2O to N titratable with hypobromite decreases though the urine rapidly acquires an acid reaction and the production of ketamic acids increases. It therefore appears that in starvation the organism reacts quite differently from when it is in a state of diabetes when acidosis and hyperammoniuria set in. The decrease in the alk. reserve observed in exptl. scurvy is also found in total inanition, but not in partial inanition when the animals receive a normal proportion of antiscorbutic juice. The loss in alk. reserve therefore takes place by an entirely different mechanism in avitaminosis and in total inanition. Hence, in troubles of nutrition, such as athrepsy of nurslings, which involve an unbalancing of the alk. reserve and a more or less pronounced urinary excretion of ketamic compds., it seems advisable to administer both sugars and alkali, *e. g.*, glucose and $NaHCO_3$. A. Papineau-Couture

The role of calcium in nutrition and biologic processes of the animal organism. A. V. Popova. Inst. for Protection of Maternity and Infancy, Leningrad. *Arkh. Biol. Nauk* **28**, 377–92(1928).—Feeding expts. with guinea pigs upon a normal or scurvy-producing diet demonstrated that the absence or presence of vitamin C has no effect upon the quantity or the Ca balance of the blood. A fat-free diet fed to pregnant rats resulted in litters displaying deficient processes of ossification, pointing to a definite significance of lipoids for the assimilation of Ca. The administration of $CaCl_2$ in the milk, *per os*, or subcutaneously did not affect the Ca balance in normal guinea pigs. Subcutaneous injection brought about local skin reactions and occasionally necrosis. In guinea pigs receiving a diet rich in vitamin C and subsequently inoculated with a virulent culture of tubercle bacilli the development of the infection is delayed and it assumes a somewhat benign type. This is accompanied by a normal or only slightly elevated blood Ca level. Scorbutic guinea pigs in the stage of great loss of Ca show a pronounced tendency to rapid fatal infection with tuberculosis. The great diagnostic value of the blood Ca concn. in tuberculosis and scurvy is emphasized. W. A. P.

Infantile rickets. Treatment by intramuscular injection of a cod-liver oil concentrate. Lawson Wilkins and Benjamin Kramer. Johns Hopkins Univ. *Bull. Johns Hopkins Hosp.* **40**, 52–7(1927).—The intramuscular injection of an ether soln. of a cod-liver oil concentrate in 2 children suffering from active rickets gave very satisfactory results. Fresh calcification of rachitic cartilage occurred within 3 weeks and the changes in the concn. of Ca and P in the blood were identical to that observed previously following administration of cod-liver oil orally. This proves that the effect of cod-liver oil is not on the intestinal mucosa, but it is a general effect exerted through the circulation. G. F. Reddish

Calculation of the normal pelidisi index for the Chinese. Paul H. Stevenson. Peking Union Med. Coll. *Chinese J. Physiol., Report Series 1928*, No. **1**, 1–12.—The racial norm for the pelidisi index for the Chinese approaches 90 as a basic standard except for the newborn in which 93 represents the normal mean. The degree of variation on either side of the racial mean for normal persons is such that any index lying between 80 and 100 may be considered as falling within the range of normal variation. **Calculation of the body surface area of Chinese.** *Ibid* 13–24.—With revised region consts., the use of the linear formula (DuBois) method of calcg. the surface area of the Chinese body was found to agree with the actually measured surface area to within an av. of 1.27%. **Estimation of the surface area of the Chinese.** Susan S. Waddel, Chung-Hsin Han and Yen-Ping Ch'en. Shantung Christian Univ. *Ibid* 25–32.—The surface area of 74 Chinese subjects was estd. by the DuBois linear formula and by the DuBois height-wt. formula. The results show that the error in the application of these formulas to the estn. of surface area of Chinese is little, if any, greater than with American subjects. L. W. Riggs

Basal metabolism in anthropology. Francis G. Benedict. Carnegie Inst. of Washington, Nutrition Lab., Boston. *Chinese J. Physiol., Report Series 1928*, No. **1**, 33–8.—Six investigators were furnished identical app. and accessories for detg. basal metabolism of native subjects in 6 countries, resp., China, Jamaica B.W.I., Peru, Yucatan, New Guinea and S. Australia. Basal metabolism measurements are to have a distinct phase in anthropology as well as in physiology and pathology. The results thus far obtained indicate that a difference in basal metabolism may be due to a racial factor. The slightly lower basal metabolism of Orientals does not indicate a racial deficiency. L. W. Riggs

Basal metabolism of Chinese and Westerners (British). H. G. Earle. Univ. Hong-Kong. *Chinese J. Physiol., Report Series 1928*, No. **1**, 59–79.—The basal metabolic rate of 166 Chinese was detd. in 310 individual expts. According to the DuBois standards, the surface being calcd. with the height-wt. formula of DuBois—the basal metabolic rate of these subjects averaged 8% too low. The rate was also low as com-

pared with the Harris-Benedict and Dreyer standards. The basal metabolism of 31 Chinese in Peking calcd. on the basis of linear measurements of surface was only 2.3% lower than the DuBois standards. That of a group of 10 non-Chinese Orientals in Hong Kong was about 10% below the standards of DuBois, Dreyer and Harris-Benedict standards. That of 5 Orientals in London was 6.5 to 8.5% below all 3 standards, and that of 41 Westerners in Hong-Kong and Peking 7% below the DuBois standards (surface area estd. by the DuBois height-wt. formula). **Addendum to Professor Earle's report. Data and observations of several factors influencing basal metabolism in China.** HEINRICH NECHELES. Peking Union Med. Coll. *Ibid* 80-92.—The effects of season, temp., humidity and growth rates are discussed. The data indicate that the use of the height-wt. formula for normal Chinese may involve an error as much as 10%. In large series this would tend to give too high averages. It is suggested that the DuBois-Stevenson formula be used in future detns. of the body surface of Chinese, in addn. to the original formulas, because the existence of differences in the surface areas of different parts of the body may possibly be of importance. L. W. RIGGS

Diet of coolies in Changsha. MAUDE N. POWELL. Hunan-Yale Coll. Med. *Chinese J. Physiol., Report Series 1928,* No. 1, 129-34.—The diet of 63 coolies in Changsha showed an av. intake per person per day of 67.1 g. of protein, 27.2 fat and 604.9 carbohydrate, total 3008 cal. The av. body wt. was 54.66 kg., which would give 55 cal. per kg. as against 40 cal. per kg. in the West. The larger intake is believed to be due to the low coeff. of digestibility of the rice which constitutes the bulk of the diet. L. W. RIGGS

Study of dietaries in Peking. HSIEN WU AND DAISY YEN WU. Peking Union Med. Coll. *Chinese J. Physiol., Report Series 1928,* No. 1, 135-52.—The diet of the av. middle class Chinese, while adequate in fuel value, is suboptimal in proteins and vitamins A and D, probably adequate in vitamins B and C, and low in Ca and P. There is a prevalence of deficiency diseases. There are probably many cases of mild forms of deficiency which are not recognized. The differences between the diets of Chinese and those of Occidentals are able to account for the difference in physique and energy between them. L. W. RIGGS

Modes or utilization by the organism of the energy liberated by oxidations and the problem of the alimentary value of alcohol. ÉMILE F. TERROINE AND R. BONNET. *Compt. rend.* 187, 359-61(1928).—The oxidations which are carried on in the organism may be divided into 2 categories with respect to the energy which they liberate: in one, of which the oxidation of glucose is a type, the oxidations are entirely utilized for all kinds of work; in the other, of which the oxidation of alc. is a type, the oxidations give only heat. Alc. is uniquely a heat producer. L. W. RIGGS

Content of the kidneys in water, aliphatic acids and cholesterol in normal guinea pigs and in guinea pigs subjected to a scorbutigenic diet. (MME.) L. RANDOIN AND (MLLE.) A. MICHAUX. *Compt. rend. soc. biol.* 99, 584-6(1928); cf. *C. A.* 22, 3913.—The kidneys, unlike the spleen and suprarenals, of the guinea pig do not increase in vol. or wt. when the animal is fed a ration deprived of antiscorbutic vitamin. The content of the kidneys in H_2O, fat and cholesterol remained practically the same in guinea pigs on a diet deprived of the antiscorbutic factor as in animals on a complete or natural ration. L. W. RIGGS

Attempt at physiologic isolation of the vitamin which provokes dyscarbonuria and the urinary elimination of the intermediate products of the metabolism of the sugars. JEAN ROCHE. *Compt. rend. soc. biol.* 99, 589-90(1928); cf. *C. A.* 22, 114.—In a dog fed for 8 months on a diet deficient in vitamins A, B and C, the urinary C/N ratio increased from 0.74 to 1.27, the lactic acid output increased about 20 times and the AcH about 15 times the normal figure. Body wt. fell from 13.6 to 8.9 kg. The addn. of vitamin B alone to the diet was followed by a return of the C/N ratio, lactic acid and aldehyde to the normal figure. Body wt. returned to normal only after the substitution of a N equiv. amt. of grain albumin for casein in the diet. L. W. RIGGS

Activation of ergosterol by ultra-violet irradiation. G. ROUSSEL AND G. GUILHON. *Compt. rend. soc. biol.* 99, 592-4(1928).—Tests upon white rats with irradiated ergosterol prepd. from beer yeast by the method of Windaus, Hess and Rosenheim (cf. *C. A.* 22, 2174, 2770, 3197) confirmed the findings of these authors. The irradiated ergosterol showed antirachitic properties even in doses as small as 0.001 mg. per day. L. W. R.

The comparative nutritive value of the proteins of linseed meal and cottonseed meal for different animals. R. M. BETHKE, G. BOHSTEDT, H. L. SASSAMAN, D. C. KENNARD AND B. H. EDDINGTON. Ohio Agri. Expt. Sta. *J. Agr. Research* 36, 855-71 (1928).—The proteins of linseed and cottonseed meals were equally well digested, pos-

sessed the same biological value and were equally efficient in supplementing the proteins of corn when fed on the same protein basis to young rats. Rats and pigs did not respond alike when fed identical rations contg. linseed and cottonseed meals. The latter proved toxic to pigs. The feeding of linseed and cottonseed meals to growing chicks, either as the chief source of protein or in combination with an animal protein, showed that the proteins of cottonseed meal were more efficient than those of linseed meal. No toxic effects were observed with this species. Evidence is presented which indicates that the age or maturity of the chicken may influence its response to linseed- or cottonseed-meal feeding. Cottonseed and linseed meals were of nearly equal value when fed to beef calves in combination with alfalfa hay, corn silage and corn. It is pointed out that not all species of animals respond alike to linseed- and cottonseed-meal feeding and that the conflicting results obtained with these two feeding stuffs may, wholly or in part, be accounted for on the basis of toxicity or species variation. W. H. Ross

The dietetically and therapeutically important constituents of killed yeast. Max Winckel. *Münch. med. Wochschr.* **74**, 1274–5; *Chem. Zentr.* **1927**, II, 1359.—Citing the literature and his own former work, W. demonstrates that killed yeast has dietetically and therapeutically a higher value than living yeast. The directions given in the 6th edition of the German Pharmacopeia for examg. fermentative medicinal yeast are supposedly based on wrong assumptions. G. Schwoch

Ergosterol, isolated from a Japanese edible mushroom, Cortinellus shiitake. Mizuho Sumi. Inst. Phys. and Chem. Research, Tokyo. *Proc. Imp. Acad. (Japan)* **4**, 116–9(1928).—The com. air-dried sample (15 kg.), extd. with Et_2O and EtOH, gives 35 g. ergosterol, m. 158–9°, α_D^{17} —128°, showing all the reactions of Tanret's ergosterol. Irradiation expts. (ultra-violet rays) are reported. The *C. shiitake* powder was also irradiated; 0.2 g. of this was nearly equiv. to 0.5 mg. of irradiated ergosterol in its antirachitic potency. C. J. West

Vitamins and tumor growth. I. The deficient vitamin B content of chicken sarcoma tissue. Waro Nakahara and Eiichi Somekawa. Inst. Phys. Chem. Research, Tokyo. *Proc. Imp. Acad. (Japan)* **4**, 440–3(1928).—Pigeons fed on polished rice and dried chicken sarcoma manifest symptoms and die of polyneuritis at about the same rate as control pigeons fed on polished rice alone. While the daily intake of only 0.01 g. of dried chicken liver protects rats from the reduction of body wt. on vitamin-B-deficient diet, 10 times that amt. of similarly dried sarcoma tissue fails to give similar protection. Thus, the vitamin B content of the tumor tissue may be very small, if not practically nil. C. J. West

The reaction of the intestinal contents of dogs fed on different diets. W. R. Graham and E. S. Emery. *J. Lab. Clin. Med.* **13**, 1097–107(1928).—Three dogs were fed diets considered normal for these animals. The others were given a preponderance of protein, fat or carbohydrate for 2 weeks, and then killed instantaneously 24 hrs. after eating and the digestive tract was studied immediately. All showed about the same thing. The p_H ranged from 6.2 to 6.5 in the duodenum. Thence it became gradually more alk. as it approached the ileocecal valve to become more acid in the cecum. These results suggest that the reaction of the upper intestine is acid as a result of the HCl and bile and becomes less so as the alk. succus entericus becomes the more dominant factor. There was no evidence that 2 weeks' feedings of different food substances influenced the p_H of the intestinal tract. Ethel W. Wickwire

Hypervitaminosis through large doses of vitamin D. H. Kreitmair and Th. Moll. *Münch. med. Wochschr.* **75**, 637–9(1928).—Vitamin D was administered to animals in the form of irradiated ergosterol in olive or sesame oil. Large doses were administered and usually effected a loss in wt. and eventually death. In white mice 3 mg. daily produced a 37% loss in wt. and death in 15 days. In white rats 10 mg. daily produced a 24% reduction in wt. and death in 10 days. In guinea pigs 50 mg. daily produced a 28% reduction in wt. and death after 36 days. In rabbits 10 mg. daily produced a 20% loss in wt. and death after 10 days. In cats 20 mg. daily produced a 43% loss in wt. and death after 14 days. In dogs 20 mg. per kg. daily produced a 47% loss in wt. and death after 34 days. In hens 50 mg. daily and in axolotl 10 mg. daily produced no effect. Smaller doses produced death after a longer time or merely a loss in wt. The sensitivity of various animals to overdoses of vitamin D varies. Overdoses of vitamin D accelerate the metabolism, particularly that of Ca. R. C. Willson

Ultra-violet irradiation of dehydroergosterol (Windaus, Linsert) 10.

Lecoq, Raoul: **Recherches expérimentales sur les vitamines B contenues dans les levures, dans leurs extraits et dans leurs milieux de culture.** Paris: Vigot. 68 pp. F. 15. Reviewed in *Bull. soc. hyg. aliment.* **16**, 359–61(1928).

E. K. MARSHALL, JR.

Energy metabolism of women while ascending or descending stairs. FRANCIS G. BENEDICT AND HAZELTENE S. PARMENTER. Carnegie Inst. of Washington and Mount Holyoke College. *Am. J. Physiol.* **84,** 675–98(1928).—A portable app. for detg. O_2 consumption is described. The essential parts are: mouthpiece, valves, soda-lime absorber to remove CO_2, and 3 rubber bags for O_2, two of which contain measured amts. of O_2. For horizontal walking at 34, 65 and 89 meters per min., the total heat production per horizontal kilogram meter was 1.18, 0.79 and 0.87 g. cal., resp. The increment in heat production above that required for standing was: 0.64, 0.52 and 0.67 g. cal. per horizontal kilogram meter. Ascending stairs required about 15 times as much energy expenditure and descending stairs about 5 times as much as did horizontal walking. The mechanical efficiency of the subjects in stair climbing was computed at about 25%. J. F. LYMAN

Further experience concerning the action of menformone on the mammary glands. O. O. FELLNER. *Deut. med. Wochschr.* **54,** 922(1928).—**Reply to above.** E. LAQUEUR. *Ibid* 923. ARTHUR GROLLMAN

Formation of lactic acid in excised organs. HAROLD E. HIMWICH AND SHELTON A. JACOBSON. Yale Univ. *Proc. Soc. Exptl. Biol. Med.* **25,** 53–4(1927).—Paired organs of dogs were studied. The control organ was rapidly triturated in chilled alc., the other was triturated in Ringer or buffered phosphate soln. at p_H 8 and then incubated at 37.5° for 3 to 10 hrs. Extn. and purification were carried out by the Meyerhof method. Lactic acid was detd. by the oxidation method as modified by Friedmann, Cotonio and Shaffer. The kidney, testis, parotid, submaxillary, thyroid and cerebrum were studied. In these tissues, incubation increased the lactic acid from $1^1/_2$ to 30-fold. C. V. B.

Selective distribution of portal blood in the liver. An experimental study. GLOVER H. COPHER AND BRUCE M. DICK. Washington Univ. *Proc. Soc. Exptl. Biol. Med.* **25,** 328(1928).—Trypan blue injected into the veins of the stomach and spleen was almost entirely conveyed by the blood to the left half of the liver. Dye injected into the veins of the upper part of the duodenum, the head of the pancreas and the jejunum was carried to the 2 right lateral lobes. When the veins of the colon were injected the dye was distributed to all parts of the liver but more particularly to the large lobe of the left side. C. V. B.

The uretero-vesical valve and experimental production of hydroureter without obstruction. CHARLES M. GRUBER. Washington Univ. *Proc. Soc. Exptl. Biol. Med.* **25,** 329–31(1928).—Excised bladders and attached ureters of various animals were subjected to increased intravesical pressure; intraureteral pressure did not increase. In dogs the intravesical ureter was excised on one side; the ureter remained patent. Five months later hydroureters were found in the cases where the valve had been removed. C. V. B.

Vasoconstriction in the liver. FRED R. GRIFFITH, JR., J. YORK AND A. ZACHMYS. Univ. of Buffalo. *Proc. Soc. Exptl. Biol. Med.* **25,** 399–401(1928).—In expts. on cats under urethan or chloralose anesthesia, records were taken of the vol. of a hind leg, a kidney, an intestinal loop and the liver during stimulation of the hepatic nerves. The rise of arterial blood pressure which resulted from stimulation of the hepatic nerves was accompanied by, or resulted in, a passive dilatation of the leg, kidney and intestines; the liver alone decreased in vol. Hence the rise in blood pressure appears to be due merely to the forcing of blood from the extensive vascular bed in the liver into the general circulation rather than to the release of a vasoconstrictor substance from the liver into the blood stream. C. V. B.

Relation between absorption and utilization of galactose. CARL F. CORI AND GERTY T. CORI. Univ. of Buffalo. *Proc. Soc. Exptl. Biol. Med.* **25,** 402–6(1928).—For an equal amt. of galactose absorbed, the utilization is highest with lactose, intermediate with a galactose-glucose mixt. and lowest with galactose. This is ascribed to the different rate of absorption of galactose in the 3 cases, the rate being lowest with lactose, intermediate with a galactose-glucose mixt. and highest with galactose. During the absorption of galactose there is no rise in the glucose content of the blood. **The rate of excretion of galactose.** *Ibid* 406–8.—After the establishment of an initial equil., due

to the penetration of galactose into the tissues, the rate of excretion and utilization of galactose remain const. from hr. to hr. The amt. of galactose utilized per unit of time increases with increasing rates of absorption. C. V. B.

Duodenal drainage of the human gall bladder EDW. A. BOYDEN AND A. M. SAUNDDERS. Univ. of Ill. *Proc. Soc. Exptl. Biol. Med.* **25**, 458–62(1928).—When $MgSO_4$ is injected into the duodenum it induces marked contraction of a distended gall bladder and consequent expulsion of bile. Various theories as to the mechanism of action are discussed. **Reflex inhibition of the human gall bladder.** EDWARD A. BOYDEN AND L. PARMACEK. *Ibid* 462–4.—In studying the effect of drinking water on the gall bladder in 10 patients considerable variation was found, ranging from an individual with a discharge of 24 cc. of bladder bile after a glass of water to one who reacted by dilation of the gall bladder. The latter subject was markedly vagotonic and the former was sympaticotonic. It is suggested that the gall bladder is under nervous as well as hormonal control. C. V. B.

Production of placentomata in rats injected with anterior hypophyseal fluid. L. BROUHA. Univ. of Calif. *Proc. Soc. Exptl. Biol. Med.* **25**, 488–9(1928).—In rats injected daily with anterior hypophyseal fluid, and presenting numerous persistent corpora lutea, it is possible to obtain regularly large placentomata if the injury of the uterine mucosa is produced around the 5th day of injections and the animal killed 5 to 7 days after operation. If the injury of the uterine mucosa is made the day before the injections started, it is not possible to obtain large placentomata. A slight enlargement at the sites of injury may be seen. If the injury is made after 10 days or more, placentomata are never obtained. C. V. B.

Production of placentomata in normal and ovariectomized guinea pigs and albino rats. CHARLES K. WEICHERT. Univ. of Wis. *Proc. Soc. Exptl. Biol. Med.* **25**, 490–1(1928).—Corpus luteum hormone was injected into normal rats for 2 days following estrum, at which time the uterine mucosa was stimulated and the injections were continued for 4 days. The rats were killed and placentomata were found. Ovariectomized rats were treated with corpus luteum hormone in the same way and no placentomata were formed. If estrum was produced artificially by injection of the follicular hormone, then the above described treatment produced placentomata. In guinea pigs, which on the 4th day after estrum were ovariectomized and in which the uterine mucosa was stimulated, no placentomata were noted. If the corpus luteum hormone was administered at the time of operation and continued for 4 days, placentomata were formed on stimulation of the uterine mucosa. Guinea pigs were injected daily with corpus luteum hormone from the 6th to 14th day after estrum. Stimulation on the 10th day failed to produce placentomata. C. V. B.

Relation of bone development in infants to calcium and phosphorus retention ratio. AMY L. DANIELS AND MARY K. HUTTON. State Univ. of Iowa. *Proc. Soc. Exptl. Biol. Med.* **25**, 794–7(1928).—Metabolism studies on infants suggested that normal calcification of the skeleton takes place when the Ca and P are retained in the proportion of approx. 2 to 1. Normal bone development appears to take place at different levels of Ca and P retentions. The size of the skeleton may depend on the amt. of Ca and P retained. It is suggested that the disproportion in the Ca and P retentions observed in rachitic infants receiving cow milk modifications are due primarily to a faulty Ca metabolism, the metabolic disturbance being related to a deficiency of vitamin D. C. V. B.

Physiological effects of temporary occlusion of the coronary vessels. DON C. SUTTON AND W. W. KING. Northwestern Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 842–4(1928).—Compression of the coronary vessels and immediately adjacent tissue as described caused pain without exception, sometimes salivation, vomiting in 1 case, a disturbance of respiration, "acute dilatation" of the heart and various changes in the electrocardiogram. Symptoms were not produced by localized compression and tearing of the myocardium or pericardium. This may be due to a high threshold of problematical pain endings in the normal cardiac muscle and pericardium. Severance of the vagi did not interfere with transmission of pain impulses in 2 dogs. Removal of the left stellate ganglion prevented the transmission of pain impulses in 2 dogs, but salivation occurred in 1 of the 2. A prompt fall of blood pressure occurred in all acute expts. on compression of the coronary vessels as described. Section of the vagi usually prevented this fall in blood pressure. Fall of blood pressure, cardiac dilatation and cardiac irritability are increased by moderate cyanosis (anoxemia). C. V. B.

Auto-digestion. IV. Antitrypsin and clotting time. H. NECHELES AND MAO-KENK CHU. Peking Union Medical College. *Proc. Soc. Exptl. Biol. Med.* **25**, 847–8 (1928); cf. *C. A.* **22**, 2622.—There is no relationship between "antitryptic" power of

the serum and clotting time of the blood. The inconsistency of changes of the "anti-tryptic" titer is confirmed. C. V. B.

Production of sugar by surviving liver. A. CARRUTHERS. Peking Union Med. College. *Proc. Soc. Exptl. Biol. Med.* 25, 850–2(1928).—When the power of the liver to produce sugar is being investigated it is not sufficient simply to est. the sugar in terms of glycogen and sol. sugar. Acid hydrolysis of the whole tissue should also be considered. C. V. B.

Inorganic substances in human blood. I. Cation and anion content of normal serum. W. H. JANSEN AND A. M. LOEW. *Deut. Arch. klin. Med.* **154**, 195–220(1927).—Av., min. and max. values (mg. %) for human blood are, resp.: (cations) Na 320, 315, 350; K 20, 18, 22; Ca 10.2, 9.4, 11.0; Mg 2.34, 1.8, 2.8; (anions) Cl 360, 335, 370; P 13, 10.1, 14.5; S 141.5, 117, 166.6; ratio Na:K 16.5, Ca:Mg 4.0–5.0; K:Ca 2.0. At an av. CO_2 tension of 40 mm. the carbonic acid capacity is 118.6 mg. % CO_2. The chloride: hydrogen carbonate quotient is 2.2. B. C. A.

Comparative study of the physical characters and chemical components of blood and of serous discharges. A. ORSI AND L. VILLA. *Folia clin. chim. micro.* **1**, 190–3 (1926).—The d. of inflammatory discharges approaches that of the plasma. The refraction and viscosity increase with exudates, and, after a discharge, change in a manner depending on the rapidity with which the discharge reforms; in the plasma these characters increase after a discharge and in the case of transudates diminish in both the liquid and the plasma. In general, the elec. cond. varies inversely with the protein concn., systematic variations in relation to certain salts (chlorides) being apparent. The p_H value varies greatly with liquids of either similar or different character, and the alk. reserve in general follows the p_H value. The ratio between the amts. of chloride in the plasma and the corresponding liquid remains const., and the proportions of total non-protein N and of carbamide vary within very narrow limits. Dextrose is always found, being usually in less amt. in the liquids. Cholesterol is present in min. amts. in the transudates, but the exudates contain it in determinable quantity, even when that present in the plasma is normal. Bilirubin is constantly present in the liquids in smaller proportion than in the plasma. B. C. A.

Effect of hemolytic substances on red blood corpuscles and the mechanism of hemolysis. K. C. SEN AND S. K. BASU. *J. Indian Chem. Soc.* **5**, 1–20(1928).—It is suggested that hemolysis is due, in certain circumstances, either to the coagulation or the extreme peptization of the colloidal matter constituting the wall of the cell, in which cases disintegration of the cell occurs by the formation of cracks or by dissolution of the wall. Hemoglobin forms a neg. charged sol in water which is sensitized by acids and peptized by alkalies and bile salts. Saponin causes pptn. in slightly acid, but not in alk. solns. Mixts. such as KOH and $BaCl_2$ or KCl and K oleate have antagonistic actions. Lecithin sol is sensitized by hemoglobin towards $BaCl_2$ (at high concn. a slight peptizing action is observed) and peptized by saponin and bile salts. The latter also peptize cholesterol. The inhibitory action of egg protein and blood serum on the hemolysis of the red blood corpuscles of sheep is due to antagonistic action of the peptizing and sensitizing agents. Na glycocholate is a much more powerful hemolytic agent than Na taurocholate. B. C. A.

The influence of the circulation in the brain upon fatigue. KIYOSHI HORIUCHI. Kaiser Wilhelm-Inst. für Arbeitsphysiologie und das physiol. Lab. der deutschen Hochschule für Liebesübungen, Berlin. *Arbeitsphysiol.* **1**, 75–84(1928).—The purpose was to det. the effect of diminished circulation in the brain upon the onset of fatigue in dogs as measured by the energy output in running upon a treadmill. The respiration expts. were made by means of a small Benedict app. connected to the animal by a mask. The periods were 5 min. with intervals of 5 to 10 min., the dog running continuously. The first series were made upon normal animals, until they were well trained. Then the vertebral arteries were ligated. Later, a second operation was made in which special clamps were placed upon the carotid arteries and left in place until healing was complete. The expt. after the ligating of the vertebral arteries did not show an effect either upon the basal metabolism or upon the onset of fatigue. The partial closure of the carotid arteries produced no change in the basal metabolism except when there was a considerable interference with the blood flow in the brain, and then there was a slight increase. There was a marked increase in O absorption per 100 m. during the work periods at speeds from 64 to 70 m. per min. even from the start of the work. In the following periods, the greatest increase occurred in the expt. in which one carotid artery was entirely closed. T. M. CARPENTER

The effect of voluntarily increased breathing upon the recovery after muscular work. ERNST SIMONSON. Sozialhygienische Untersuchungsamt., Frankfurt a.M.

Arbeitsphysiol. **1,** 88–101(1928); cf. *C. A.* **21,** 2314.—The recovery processes after muscular work are accelerated when there is voluntarily increased breathing in the period following the muscular work. This is ascribed to an increased alveolar O_2 tension, a diminished alveolar CO_2 tension and the favorable mechanical action of the movements in breathing upon the circulation. T. M. CARPENTER

Colloidal chemical changes of the muscle of warm-blooded animals in fatigue. GERHARD SCHMIDT. Univ. Frankfurt a.M. *Arbeitsphysiol.* **1,** 136–53(1928).—The capacity to synthesize hexosephosphate from inorg. phosphoric acid and carbohydrate was materially decreased in the finely divided muscles of rabbits which had been fatigued by strychnine convulsions. The conclusion was also drawn from a series of expts. on rabbits that in sufficiently severe fatigue, physical and chem. changes in the condition of the muscles took place which brought about a weakening of the synthetic capacity of finely divided muscle, and that this is a phenomenon accompanying fatigue, similar to that found in earlier investigations on frog muscle. The decrease in the synthetic capacity could not be ascribed to the high phosphoric acid content of the muscle or to the low glycogen content. T. M. CARPENTER

Studies in the physiology of work. VII. Physiology (energy economy) of shoveling. KURT WENZIG. Kaiser-Wilhelm-Inst. für Arbeitsphysiologie, Berlin. *Arbeitsphysiol.* **1,** 154–86(1928).—The output of energy in shoveling loads to a higher level was detd. by means of a respiration expt. with the Douglas and Haldane method. The loads varied from 0.29 to 13.9 kg., the height to which the loads were thrown ranged from 0.5 to 2.5 m., and the handle lengths were 48 to 84 cm. The rate of shoveling was 8 per min. The heat output per shovel lift at 1 m. height with medium length of shovel varied from 345 cal. with a load of 0.29 kg. to 1224 with a load of 13.90 kg. and the max. energy cost per kg.-m. of external work performed varied from 134 cal. with a load of 2.75 kg. to 49.2 with a load of 13.9 kg. thrown to a height of 1 m. Above and below this height conditions were more favorable for a lower heat output per unit of work.
T. M. CARPENTER

The relation of physiology to other sciences. C. A. LOVATT EVANS. *Nature* **122,** 442–5(1928); *Science* **68,** 259–64, 284–91(1928). E. J. C.

The present position of hormone research. FRITZ LAQUER. *Z. angew. Chem.* **41,** 1028–33(1928). E. J. C.

Phosphorus metabolism. A. YU. KHARIT AND A. I. LIVSHITZ. *Arkh. Biol. Nauk* (Moscow) **27,** 89–99(1927); *Chem. Zentr.* **1927,** II, 2688.—The *P content of dog blood* was studied under various conditions. The *v. portarium* had the most P, and the *r. renalis* the least, because the liver and the kidneys are able to retain P from the blood. The kidneys can eliminate up to 20% of the P administered. Blood serum contains $3.1–7.2 \times 10^{-5}$ g. per cc. of inorg. P, $2.6–3.5 \times 10^{-4}$ g. per cc. of total P. The P detns. were carried out according to Denigès' method (*C. A.* **17,** 1974). The method is simple and gives very reliable results. C. C. DAVIS

The elimination of some widely used barbituric acid compds. in the urine. J. HALBERKANN AND F. REICHE. Allgem. Krankenh., Hamburg-Barmbeck. *Münch. med. Wochschr.* **74,** 1450–2; *Chem. Zentr.* **1927,** II, 1718.—The problem whether *luminal* and *noctal* are eliminated unchanged by the urine was investigated. It was found that luminal is eliminated unchanged, but that after the administration is stopped, its excretion continues for a long time, in 1 case a period of 11 days passing by before the elimination was complete. On the other hand noctal was soon decompd. in the organism, only 2–3% being eliminated unchanged. It was impossible to recover noctal in pure form from the urine so that it could be identified by its phys. properties. Considerable noctal (up to 20%) underwent transformation into the harmless isopropylacetonylbarbituric acid. As a result of the extensive decompn. of noctal in the body, it may be assumed to have no cumulative effect. C. C. DAVIS

Calcium-fixing power of the tissues—muscle, liver, lung. B. RAPINESI. Univ. Naples. *Arch. farmacol. sper.* **45,** 187–92(1928).—In the normal rabbit the Ca content of the muscle, liver and lung is subject to rather wide variations. The Ca-fixing power of these tissues after intravenous injection of Ca gluconate is very striking. This power of fixation by the muscle is inversely proportional to the ordinary Ca content. The Ca thus retained persists until the 9th day; then it is slowly eliminated. It appears that there exists in the tissues a reserve of Ca which is capable of more or less rapid mobilization, and this reserve can be increased by parenteral, and perhaps enteral, administration of Ca. On the other hand, the blood Ca is more or less const. and is not influenced to any noteworthy extent by administration of Ca salts. A. W. DOX

Mineral metabolism in depancreatized dogs. I. The effect of pancreas extirpation upon the composition of the blood and urine. MEYER-BISCH AND DOROTHEE

BOCK. Universitätsklinik Göttingen. *Z. ges. exptl. Med.* **54**, 131–44(1927).—In 27 out of 28 cases the blood Cl diminished and in 11 out of 15 the Na showed a parallel decrease. The alkali reserve was reduced to 6 vol. % in 13 out of 14 cases. In 12 cases the blood K was diminished in only 1 and increased in 5, while the Ca was diminished in 12 out of 16 cases. The output of Cl in the urine was diminished. **II. Effect of pancreas extirpation on the sodium and chlorine content and the swelling of various organs.** *Ibid* 145–51; cf. *C. A.* **21**, 2028.—The Cl in skin and liver was decreased. The Na in muscle and skin did not parallel the Cl. Muscle showed an increased swelling in distd. water, while liver showed a decreased swelling. F. L. D.

The standardization of ovarian hormones. FR. UHLMANN. Ciba, Basel. *Z. ges. exptl. Med.* **55**, 486–504(1927).—A critique of methods of standardization. Bibliography. F. L. DUNN

The chylomicron (free fat) content of the blood in infants. L. C. SCHROEDER AND E. HOLT. *Am. J. Diseases Children* **31**, 201–17(1926); *Physiol. Abstracts* **11**, 218.—Examn. of the blood of infants by dark-ground illumination shows that the chylomicron content varies directly with the fat content of the food, butter giving the most marked increase among the foods studied. H. G.

The hydrogen-ion concentration of the stools of new-born infants. R. C. NORTON AND A. T. SHOHL. *Am. J. Diseases Children* **32**, 183–91(1926); *Physiol. Abstracts* **11**, 478.—Using the colorimetric method, the authors found that the acidity increases gradually from the meconium av. (p_H 6.1) to that characteristic of stools of breast-fed infants (p_H 4.6 to 5.2) in 6 days, the meconium being comparable to fasting feces. H. G.

Respiratory metabolism in infancy and in childhood. S. Z. LEVINE AND J. R. WILSON. *Am. J. Diseases Children* **33**, 204–12(1927); *Physiol. Abstracts* **13**, 103.—Respiration chamber observations showed that healthy children and most sick (afebrile) children eliminate 25% of the total heat produced in vaporization through skin and lungs, and 75% by way of radiation and conduction. H. G.

Researchs on lactation. MARGARET F. LOWENFELD AND SIBYL T. WIDDOWS. London School of Med. for Women. *J. Obstet. Gynaecol. Brit. Empire* **35**, 114–30(1928).—In a daily study of the lactation of a group of women, Ca and ash did not vary with time or method of taking sample. Fat content varied directly with pressure applied to ext. and inversely with the amount of fluid in the breast. GEORGE R. GREENBANK

Interrenin, the hormone of the cortex of the suprarenal gland. M. GOLDZIEHER. U. I. Z. Hosp., Brooklyn, N. Y. *Klin. Wochschr.* **7**, 1124–5(1928).—Macerate fresh beef suprarenals and ext. with 0.2 *N* HCl. Filter. Sat. the filtrate with NaCl and dissolve the active ppt. in 70% alc. Addn. of 5 vols. amyl alc. produces a ppt. which is dissolved in 80% alc. Remove solvent *in vacuo* and redissolve in 80% alc. Reppt. with amyl alc. The white, amorphous powder so obtained is free from protein, is readily sol. in alc. and in dil. acids and insol. in H_2O, dil. alkali, Et_2O or $CHCl_3$. It contains 24% Cl and appears to be a chloride. An analysis, based on the Cl-free product, gives 13.3% N, 43% C, 5.1% H, 37.3% O and 1.3% S. The pharmacol. behavior is discussed. MILTON HANKE

Variations in the concentration of potassium, calcium and choline after stimulation of the sinus caroticus in dogs. D. DANIELOPOLU, MAXIM M. I. DANIEL AND G. G. PROCA. *Klin. Wochschr.* **7**, 1329(1928).—Stimulation of the sinus caroticus leads to a marked increase in the K content of blood and a small increase in the amt. of Ca and choline. MILTON HANKE

Sexual hormone in male urine. S. LOEWE, H. E. VUSS, F. LANGE AND A. WÄHNER. *Klin. Wochschr.* **7**, 1376–7(1928).—Human, male urine may contain testicular hormone as well as the female sexual hormone. It is possible to separate these two (method not described) and it can then be shown that the testicular hormone does not give the Allen-Doisy test. MILTON HANKE

Diagnosis of pregnancy by demonstrating the presence of the hormone of the anterior lobe of the hypophysis in the urine. S. ASCHHEIM AND B. ZONDEK. Charite, Berlin. *Klin. Wochschr.* **7**, 1404–11, 1453–7(1928); cf. *C. A.* **22**, 1182.—An excess of ovarian hormone and of the hormone of the anterior lobe of the hypophysis is produced during pregnancy. These hormones appear in large quantities in the urine. The demonstration of ovarian hormone in small amounts of urine cannot be used for the early diagnosis of pregnancy because conditions other than pregnancy also lead to the excretion of this hormone. The demonstration of hypophyseal hormone in 1.2 to 2.4 cc. of urine is an almost certain proof of pregnancy. Clinical evidence is presented in abundance. For details of the method see *C. A.* **22**, 2597. MILTON HANKE

Purine metabolism of muscle and the mother substance from which ammonia is

produced in muscle. J. K. Parnas. Univ. Lwow, Lemberg. *Klin. Wochschr.* **7,** 1423–4(1928); cf. *C. A.* **21,** 2928.—The predominant purine base of resting muscle is adenine. It probably occurs as adenine nucleotide. Any change in the muscle that leads to the production of NH_3 converts adenine into hypoxanthine; adenine nucleotide is converted into inosinic acid. This change occurs instantly when the muscle is injured mechanically and it occurs slowly when muscle is stored. 95% of the adenine (or hypoxanthine) exists, in the muscle, as nucleotide; only 5% is present as nucleic acid. It is possible that the NH_3 that is liberated during muscular activity may also be derived from adenine by deamination. Milton Hanke

Activation of insulin in non-diabetics. E. Vogt. *Klin. Wochschr.* **7,** 1460–1 (1928).—Normal serum activates insulin. Serum that is obtained just before menstruation has the greatest activating effect. The concn. of ovarian hormone in serum is highest just at this time. Insulin is similarly activated when it is mixed with purified protein-free ovarian hormone. Serum from a castrated woman has very little activating action. Irradiation with ultra-violet light also intensifies the action of insulin. M. H.

Effects of congestion and heat on the composition of venous-blood samples together with some observations on the indirect determination of iron and chlorine in blood corpuscles. Frederick Horace Smirk. Manchester Royal Infirmary. *Biochem. J.* **22,** 739–44(1928).—An incomplete sepn. of plasma from corpuscles gives rise to errors in the estn. of corpuscular blood-chloride and corpuscular blood-iron. Congestion of the arm causes an increased percentage of chloride in the corpuscles and a reduced percentage in the plasma. Heating the arm gives rise to a transference of Cl^- from corpuscles to plasma. Venous samples should be taken with a min. of congestion. Benjamin Harrow

The disappearance of intravenously injected α-, β- and αβ-glucose from the blood. Eric N. Allott. Biochem. Lab., Cambridge. *Biochem. J.* **22,** 772–6(1928).—No difference is shown in the utilization of the α-, β-, and αβ-glucose when these are injected intravenously into rabbits. Benjamin Harrow

Lactic acid formation in muscle extracts. I. The relationship between phosphoric ester accumulation and phosphoric ester breakdown and lactic acid formation from glycogen. David Stiven. Univ. of St. Andrews. *Biochem. J.* **22,** 867–73 (1928).—Using an ext. of cat muscle, S. finds that phosphoric ester accumulation is not an essential accompaniment of lactic acid formation from glycogen. **II. The effect of sodium hexosediphosphate on the rate of ester accumulation during the incubation of glycogen in certain types of extracts.** *Ibid* 874–81.—In a mixt. of zymophosphate and glycogen in certain concns., there is less lactic acid produced than in the corresponding glycogen concn. in the absence of zymophosphate. This is usually associated with an increased accumulation of phosphoric ester in the glycogen-zymophosphate mixt. as compared with the corresponding glycogen expt. **III. Glucolysis in sterile cell-free extracts of muscle.** *Ibid* 882–88.—Glucolysis has been observed in ext. of perfused muscle after filtration through Berkefeld filters. Benjamin Harrow

How muscles contract. Ronald C. Macfie. *Science Progress* **23,** 273–8(1928).—A review of recent work on the biochemistry of muscular contraction. J. S. H.

The plasmalogen content of human serum. K. Imhäuser. *Deut. Arch. klin. Med.* **160,** 109–14(1928); cf. *C. A.* **22,** 2778.—In the serum of healthy adults the plasmalogen content lies between 20 and 40 mg. %. No difference (between the sexes) was observed in the plasmalogen content of the blood. Following a meal rich in plasmalogen (300 g. meat) the content of the blood rose sharply and sometimes exceeded 50 mg. %, but in a few hours the concn. fell to normal. A diet poor in plasmalogen (flour, rice, apples and a fat free dried milk) caused a fall in the concn. in the blood; but the min. (reached after 2 weeks' dieting) was not appreciably lower than the values sometimes found on a normal diet. No free plasmalogen was observed since this substance is extremely labile. P. Y. Jackson

Pancreatic function. I. The quantitative estimation of pancreatic secretion. Seizaburo Okada, Eiichi Sakurai, Taumoto Imazu and Kwanichi Kuramochi. Medical Clinic, Imperial Univ. Tokyo. *Arch. Internal Med.* **42,** 270–81(1928).—Fractional tests of duodenal activity were made every half hr. for 3 hrs. to eliminate variations. Of the stimulants used alc. and ether caused only an initial increase in output; HCl seemed to increase it slightly. Modifications of the Gross casein test for trypsin, Okada's colorimetric method for amylase and Rona-Michaelis lipase test were employed. The normal values in kg.-units were: 30–120, av. 70 for trypsin, 50–300, av. 140 for amylase and lipase. The highest values were 500 and 600, resp. The enzymic activity is highest between 20 and 40 years. The amt. of duodenal returns is independent of the age between 16 and 42 years. Both activity and amt. are

considerably higher in men than in women of all ages. The quantity of *bile pigment* was 2.5–61.7 mg./3 hrs., and not above 5 mg. in 86% cases; av. 9 mg. for women, 17.2 for men. Also in *Proc. Imp. Acad.* (*Japan*) 4, 131–3(1928). MARY JACOBSEN

Gastrointestinal reaction to the emotions. The role of the vegetative system C. W. LUEDERS. *Arch. Internal Med.* 42, 282–96(1928). MARY JACOBSEN

A study of lactocones. GIAN C. BENTIVOGLIO. *Pediatria Rivista* 36, 563–94 (1928).—Under the ultramicroscope human milk shows on a black background numerous luminescent granules of fairly uniform size which have a lively Brownian movement and can be easily distinguished from the fat globules, which appear as disks with luminous edge and dark center. Their no. is independent of the age of the woman, stage of lactation, fat, protein, lactose or ash content of the milk, but a high fat content runs parallel with a high content in lactocones (so called in analogy to hemocones). A high lactocone no. is rather unfavorable for the digestion of the infant. Cow milk shows few lactocones of varying size on a gray background, which consists of luminous particles just at the limit of visibility. Expts. with protein coagulants and fat solvents ($CHCl_3$ and AmOH) show that lactocones are highly dispersed *fat* micelles, 1–0.5μ, while the small particles of cow milk are *casein micelles* which do not pass a Chamberland filter. In cow milk casein probably plays the role of protective colloid for the fat; in human milk sol. albumin protects the casein. If the sol. albumin content of cow milk is brought up to that of human by the addn. of 2% albumin the gray background is replaced by a clear black one. Coagulation of casein in human milk by 3–4 min. heating produces a gray background, reduces the no. of lactocones and makes the milk appear opaque after centrifuging. The dietary consequences of these findings are discussed. M. J.

Albinism. FRANCESCO GRAZIANO. *Pediatria Rivista* 36, 948–60(1928).—In 2 albino children the adrenaline, atropine and pilocarpine tests revealed sympathetic hypertonus. The blood pressure was low. Albinism is attributed to hyperactivity of the *adrenal cortex.* MARY JACOBSEN

The role of the reticulo-endothelial system in the healing of fractures. GIAN CARLO PERACCHIA. *Rev. sud-americana endocrinol. inmunol. quimioterap.* 11, 519–53 (1928) (In Italian). MARY JACOBSEN

The instability of red cells in splenectomized animals. ELEOGARDO B. TROILO. *Rev. sud-americana endocrinol. inmunol. quimioterap.* 11, 554–6(1928).—Three guinea pigs presented 7 months after splenectomy a practically normal no. of red cells, with a slight decrease of hemoglobin and a considerable leucocytosis. This confirms Vitali's view of the inhibitory action of the spleen on leucocytogenesis. The chlorosis demonstrates the role of the spleen in Fe metabolism. The most significant effect of splenectomy is the irregular variation of the blood picture, which shows the regulatory importance of the spleen. MARY JACOBSEN

The precipitation of cholesterol in the intestine. HUGO SALOMON. *Arch. Verdauungskrankh.* 42, 204–5(1928).—Cellulose-rich foods greatly increase the pptn. of cholesterol in the intestine. FRANCES KRASNOW

Influence of hydrochloric acid on the emptying of the stomach. JEROME MARKS. Univ. Berlin. *Arch. Verdauungskrankh.* 42, 567–72(1928).—Acid delays the emptying by $^3/_4$ hr. The greater the amt. of acid, the greater the delay. FRANCES KRASNOW

Secretion of the fasting stomach—a spontaneous function. J. SCHREIBER. *Arch. Verdauungskrankh.* 43, 374–7(1928). FRANCES KRASNOW

Relationship between the color and the fat content of bovine corpora lutea. WM. L. BLEECKER. Univ. of Arkansas. *J. Am. Vet. Med. Assocn.* 73, 577–602(1928).—Degree of pigmentation does not run parallel with the amt. of fat contained in the tissue as detd. by sectioning and staining with Sudan III or as detd. by extn. using the Soxhlet method. There is no relationship between pregnancy, the stage of gestation, or the breed of the animal and pigmentation or fat content of corpora lutea. F. K.

Brief note on lactosuria in nursing women. ALDO CASTELLANI. Ross Inst. and Hosp., London. *J. Trop. Med.* 31, 213–4(1928).—Urine treated with *B. paratyphosus* exhausts all reducing sugars except lactose. Further fermentation by *B. coli* indicates the presence of lactose. All of 12 cases studied showed lactose by this method. F. K.

Formation of crystals within the red blood corpuscles. H. W. KRANZ. Universitäts-Augenklinik Giesser. *Z. Biol.* 87, 258–68(1928).—A method is described for fixing red blood cells. When thus prepd. and viewed through a polarizing microscope, they seem to show the presence of crystals. FRANCES KRASNOW

Refractometry of body fluids. III. Index of refraction of blood serum of healthy and pregnant women and their babies. SEIGO FUNAOKA AND MORIKUNI SAITO. *Acta Schol. Med. Univ. Imp. Kioto* 9, 307–25(1928). W. D. LANGLEY

The physiological effects of radiation. HENRY LAURENS. Tulane Univ. *Physiol.*

Rev. **8**, 1–91(1928); cf. *C. A.* **22**, 2956.—General review with extensive bibliography emphasizing metabolic changes. E. R. LONG

Industrial fatigue in relation to atmospheric conditions. H. M. VERNON. *Physiol. Rev.* **8**, 130–50(1928).—General review. E. R. LONG

Calcium metabolism. CORBET P. STEWART AND GEORGE H. PERCIVAL. Univ. Edinburgh. *Physiol. Rev.* **8**, 283–312(1928); cf. *C. A.* **22**, 3204.—General review with extensive bibliography. E. R. LONG

The growth and function of the corpus luteum. S. A. ASDELL. Univ. of Rochester. *Physiol. Rev.* **8**, 313–45(1928).—General review including chemistry of substances contained in corpora lutea. E. R. LONG

The digestive work of the stomach. B. P. BABKIN. Dalhousie Univ. *Physiol. Rev.* **8**, 365–92(1928).—General review with bibliography. E. R. LONG

Blood cell metabolism. II. The effect of methylene blue and other dyes upon the glucolysis and lactic acid formation of mammalian and avian erythrocytes. E. S. GUZMAN BARRON AND GEORGE A. HARROP, JR. Johns Hopkins Hosp. and Univ. *J. Biol. Chem.* **79**, 65–87(1928); cf. *C. A.* **22**, 3691.—The relationship between glucolysis and the oxidative processes in blood cells may be expressed by the ratio, *mM* of lactic acid increase/2 × *mM* glucose decrease, which is termed the *glucolytic quotient.* Normal adult mammalian red blood cells with almost no oxidative processes show a high glucolytic quotient. Nucleated erythrocytes (avian blood cells) with appreciable oxidative processes have a low quotient. The addn. of methylene blue (or dyes with similar oxidation-reduction potentials) to the blood undergoing glucolysis produces an increased sugar degradation and a diminished formation of lactic acid. This is probably due in part to the oxidation of some intermediary product. The *glucolytic quotient* is lowered. The process begins only after the glucose mol. is acted upon by the glucolytic enzyme and is converted into other unstable and oxidizable substances. It is suggested that oxidation may take place in the early stages of dissocn., before the glucose mol. is split into 3 C chain fragments, probably when the glucose mol. is esterified to hexosediphosphoric acid. This reaction requires the presence of O_2 but the addn. of cyanides does not impair the oxidative process. It is suggested that methylene blue acts as a catalyst, rendering the hexosephosphate mol. more sensitive to oxidation by mol. O_2. A. P. LOTHROP

Composition of bone. III. Physicochemical mechanism. M. J. SHEAR AND BENJAMIN KRAMER. Jewish Hosp., Brooklyn, N. Y. *J. Biol. Chem.* **79**, 125–45 (1928).—As a criterion for the formation of ppts. of Ca phosphates, the ion product $(Ca^{++})^3 \times (PO_4^{\equiv})^2$ is inadequate. No evidence has been found which satisfactorily demonstrates the presence in bones of a compd. with the formula, $Ca_3(PO_4)_2$. From data in the literature $p_{K'_{s.p.}}CaHPO_4$ is calcd. to be 6.4 ± 0.1 at 38°. At any ionic strength up to that of serum $p_{K'_{s.p.}}CaHPO_4 = 6.4 - 2.3\sqrt{\mu}$. The ion product $(Ca^{++}) \times (HPO_4^{=})$ at which calcification begins, both *in vivo* and *in vitro*, is numerically equal to the value calcd. for $p_{K'_{s.p.}}CaHPO_4$ at the ionic strength of serum. A theoretical basis is suggested for the empirical Ca × P product. In inorg. serum solns. with a p_H of 7.35, Ca × P = 1.5 × 10^7 ($[Ca^{++}] \times [HPO_4^{=}]$). Inorg. serum solns. with empirical Ca × P products less than 30 appear to be unsatd. with respect to $CaHPO_4$; calcification is not obtained with these solns. The evidence indicates that rachitic serum is definitely undersatd. with respect to $CaHPO_4$ and that normal serum is slightly undersatd. with respect to this salt. **IV. Primary calcification.** *Ibid* 147–60.—"When analyzed with the micro-technic, unashed normal rat bone gave a value of 1.99 ± 0.01 for the ratio, residual Ca:P; this is in agreement with the results of analyses of large amts. of bone by macro-methods. The proportion of carbonate in normal rat bone increases with age. The ratio, carbonate Ca:total Ca, is about 8–10% in the bones of young rats and 15–16% in those of adult rats. The proportion of carbonate Ca in rachitic rat bone is greater than that in normal rat bone of the same age. The proportion of carbonate in primary calcification is less than in the older bones of the same animals. The ratio, residual Ca:P, in primary calcification has a high value of 2.23 ± 0.03. This high ratio is interpreted as indicating the presence of a basic Ca salt in freshly deposited bone salts. The compn. of the primary calcification appears to be independent of the antirachitic reagent; high Ca:P ratios were obtained regardless of whether fresh calcification was induced by cod-liver oil concentrate, butter, irradiated cholesterol or irradiated yeast. A. P. LOTHROP

The electrical transference of calcium in blood serum protein solutions. DAVID M. GREENBERG. Univ. of Cal. Med. School. *J. Biol. Chem.* **79**, 177–82(1928).—The existence of complex Ca-protein ions has been demonstrated by the elec. transference method in blood serum to which mixts. of NaOH and $Ca(OH)_2$ were added. These

results confirm those of Loeb and Nichols (*C. A.* 21, 3946) and Marrack and Thacker (*C. A.* 20, 3182) and are not in accord with the proposal of Cameron and Moorhouse (*C. A.* 19, 2078) "that the non-diffusible Ca is bound to some org. substance which may be the parathyroid hormone." A. P. LOTHROP

Studies of gas and electrolyte equilibria in blood. XII. The value of p_K' in the Henderson-Hasselbalch equation for blood serum. A. BAIRD HASTINGS, JULIUS SENDROY, JR. AND DONALD D. VAN SLYKE. Rockefeller Inst. *J. Biol. Chem.* 79, 183–92(1928); cf. *C. A.* 22, 3917.—"The variations, due to causes which cannot be ascertained at present, are such that one does not appear justified in expressing the value of p_K' to more than 2 decimal places. Consideration of the available data indicates that, when the soly. coeff. of CO_2 in serum is taken as 0.510, and the p_H of 0.1 *N* HCl is taken as 1.08 in standardizing the electrometric p_H detns., the value of for serum at 38° is approx. 6.10. The p_K' values calcd. from the same data with Bohr α, 0.541, used by most previous authors, would be 6.13." **XIII. The dis bution of chloride and bicarbonate in the blood of normal and pathological human subjects.** A. BAIRD HASTINGS, JULIUS SENDROY, JR., JOHN F. MCINTOSH AND DONALD D. VAN SLYKE. *Ibid* 193–209.—"The distribution of Cl and HCO_3 between cells and serum has been studied in human venous blood. The distribution ratios (cell Cl): (serum Cl) and (cell $BHCO_3$):(serum $BHCO_3$) have been found to average several percents higher than in horse blood at the same p_H values. The difference approximates that calcd. by Van Slyke, Wu and McLean's equation 10 from the lesser base-binding power of the colloid constituents of human cells, indicated by the analysis of Adair (*C. A.* 19, 2211). Studies of blood from patients with nephritis (severe but not uremic), cardiac disease, pneumonia and acute arthritis, representing a fairly wide range of pathol. conditions, failed to reveal evidence that in any of these conditions the mechanism controlling the electrolyte distribution becomes qual. altered, or that very marked quant. deviations from the normal distribution ratios occur, other than the predicted r changes due to blood p_H variation. The only definite quant. deviation from the normal was a tendency for r_{HCO_3} values to be somewhat higher in part of the nephritic bloods. The failure of the r_{Cl} and r_{HCO_3} ratios to deviate in the pathol. bloods more markedly from the ratios observed at the same p_H values in normal blood appears attributable to the fact that the 2 factors which are theoretically most important in detg. the values of the ratios at any given p_H are the total base concn. in the serum and the hemoglobin concn. in the cells, and that neither of these is liable to great fluctuations in the conditions studied." A. P. LOTHROP

The hemolytic action of inorganic acids. MEYER BODANSKY. Univ. of Texas Med. School. *J. Biol. Chem.* 79, 229–39(1928).—"The order of effectiveness of the inorg. acids in producing hemolysis is: $H_3PO_4 > H_2SO_4 > HCl > HNO_3$. In the concns. necessary to produce rapid hemolysis (p_H 1.0 to 2.8), injury to the cell membrane, rather than an osmotic effect, is the main factor responsible for the disintegration of the corpuscle by inorg. acids. Human corpuscles have a somewhat lower resistance to inorg. acids than dog corpuscles. The anemic and normal erythrocytes do not differ appreciably in their resistance. In hemolysis by acids, the reaction between the cell constituents and the acid is complete before hemolysis occurs. Inorg. acids react readily with the constituents of the intact corpuscle. This is partly due to rapid diffusion, even from very dil. solns. of inorg. acids through the red blood cell membrane." **Lipoid solubility, permeability and hemolytic action of the saturated fatty acids.** *Ibid* 241–55.—Osmotic effects are involved in the hemolysis produced by fatty acids as increasing the osmotic concn. of the outside fluid retards the hemolysis. The fatty acids are effective in the following order: acetic < propionic < butyric = isobutyric < isovaleric < valeric < isocaproic < caproic < heptylic < caprylic < pelargonic < capric. Formic acid resembles the inorg. acids in its hemolytic action. The greater content of buffer substances in washed human corpuscles makes them more resistant than dog corpuscles to hemolysis by neutralizing a greater amt. of acid. Detns. of the relative concn. gradients of the acids penetrating the corpuscle and producing hemolysis show that the relations which exist closely resemble those that have been observed by other workers in a variety of phenomena in plant and animal tissues involving the primary penetration of the acids. That a close parallelism exists between lipoid soly. and the hemolytic effectiveness of the fatty acids is shown by the results of detns. of the distribution of the acids between H_2O and olive oil. A. P. LOTHROP

Factors influencing the excretion of calcium. BENOT HAMILTON AND MARGARET MORIARTY. Harvard Med. School. *Am. J. Diseases Children* 36, 450–62(1928).—The amt. of Ca excreted by infants fed upon breast milk is proportional only to the total amt. of the fixed bases, Ca, Mg, Na and K, in the milk. The increase in the p_H

of the intestinal contents, resulting from the buffering action of the fixed bases in the milk, may favor the formation of $Ca_3(PO_4)_2$ and Ca soaps, the principal forms in which Ca is excreted. The proportion of Ca excreted is increased by the addn. of small quantities of alkali to the milk given, and decreased by the addn. of small quantities of acid.

E. R. MAIN

The effect of hydrogen-ion concentration on the respiratory exchange of tissues. M. COMEL. *Arch. sci. biol.* (Italy) **11**, 145–73(1928).—Part of the data is similar to that given previously (cf. *C. A.* **21**, 2300). A complete bibliography and a detailed description of methods heretofore used are included. Additional data are given showing that in winter frogs, hibernating or non-hibernating, the consumption of O_2 and production of CO_2 are greatly reduced in contrast to spring frogs; the respiratory exchange of the latter is more than double that of winter hibernating frogs and about $1^1/_2$ times that of winter non-hibernating frogs. In spring frogs there is a rapid diminution of O_2 consumed and a similar but not proportional reduction in CO_2 produced at p_H below 5.31. At p_H 2.97 the O_2 consumed is extremely small and there is a further reduction in CO_2 produced.

PETER MASUCCI

Avitaminosis. I. Is hyperglucemia a constant phenomenon in avitaminosis? A. PUGLIESE. *Arch. sci. biol.* (Italy) **11**, 182–93(1928).—The av. normal blood sugar of 12 pigeons was 0.209%. In starved pigeons there was a small but const. reduction in blood sugar, which reached a low level and then remained const. during the inanition. Some pigeons were fed polished rice; some received grain autoclaved at 133° for 2 hrs.; a few received autoclaved grain irradiated for $^1/_2$ hr. with ultra-violet rays. Data are given showing duration of expt., loss in wt., oral temp., blood sugar and hepatic and muscle glycogen. Hyperglucemia in avitaminosis from polished rice or autoclaved grain was not a const. phenomenon. As in fasting, avitaminosis from polished rice or autoclaved grain resulted in a strong diminution of hepatic and muscle glycogen. The glycogen disappeared completely when the loss in body wt. exceeded 40%. P. M.

The limit of tolerance, glucemia and refractometric value of blood serum after sea bathing. PAOLO ROWINSKI. *Arch. sci. biol.* (Italy) **11**, 224–50(1928).—(1) Under the influence of sea baths the concn. of the protein substances in the serum increased. From 20 detns. the av. % of protein before the baths was 8.05, after the baths 8.49. These figures were calcd. from the refractive index of the serum before and after bathing. (2) The amt. of blood sugar decreased. The av. of 18 detns. was 0.116% before, and 0.102% after, bathing. (3) The limit of tolerance for glucose was raised as the hyperglucemia and glucosuria diminished. The increase in concn. of serum proteins is attributed to the elimination of water (av. loss of 20 detns. 5.49%) and dissolved salts. The increase in the "limit of tolerance" for glucose and the diminution of blood sugar under the influence of bathing are related. Theories are advanced explaining both phenomena. P. M.

Studies on the blood of fatigued animals. II. Physicochemical constants. Variations in blood content, residual nitrogen and glucose. O. M. BERNARDI. *Boll. soc. ital. biol. sper.* **3**, 123–6(1928); cf. *C. A.* **22**, 3440.—A table of physicochem. consts. of blood serum following fatigue is given; it includes the delta (Δ), elec. cond. and viscosity. Another table includes residual N and glucose based on wet and dried wt. There is a decrease in the % of H_2O; an increase in delta; a diminution of elec. cond.; an increase in viscosity and an increase in residual N. There was a decrease in glucose.

PETER MASUCCI

The metabolism of the retina at different stages of its development. CHICHIO TAMIYA. *Biochem. Z.* **189**, 114–8(1927).—Up to the 17th day of incubation of the chick the value of $Q_M^{N_2}$ is < 50, which means that the lactic acid production is < 0.2 mg. per hr. per mg. retina. The quotient then becomes doubled about the time of hatching and gradually increases to 130–163 by the end of a year. The lactic acid production again diminishes with greater age. S. MORGULIS

Can lactic acid disappear anaerobically from the muscles? F. LIPMANN. *Biochem. Z.* **191**, 442–9(1927).—Lactic acid does not disappear from cut muscles under anaerobic conditions even in the presence of NaF. S. MORGULIS

Studies on the glucolysis problem. I. Glucolysis in the blood of normal, non-diabetic dogs. BÉLA ROHNY. *Biochem. Z.* **192**, 1–7(1928).—Glucolysis in normal oxalated blood proceeds more quickly at 37° than at lower temps. and ceases at 56°. Glucolysis proceeds also in blood serum but it becomes much reduced in the first hrs. or is even overcompensated by the ensuing increase in glucose concn. This increase in glucose concn. is thought to be peculiar to the blood. Furthermore, inasmuch as the sugar increase is more pronounced in sepd. serum than in serum in contact with the red cell mass it is concluded that the latter contains substances which inhibit the sugar in-

crease. **II. Glucolysis in the blood of experimentally diabetic (depancreatized) dogs.** ZOLTÁN ASZÓDI. *Ibid* 8–13.—Blood and serum from depancreatized dogs behave similarly in the matter of the diminution or rise in the sugar concn. S. M.

Effect of attenuation of air on the hemoglobin concentration in the blood cells and the influence of the spleen on blood regeneration. L. DRASTICH. *Biochem. Z.* **195,** 189–205(1928); cf. *C. A.* **22,** 108–9, 3207.—An app. is described for maintaining low atm. pressures (down to 300 mm. Hg) over long periods of time. The hemoglobin concn. of the erythrocytes of animals kept for some time in rarefied air is somewhat below normal but increases later, which indicates a further formation of hemoglobin in the cells which were previously prematurely discharged into the blood stream. The concn. is detd. from the values of the absolute hemoglobin content of the blood and the cell vol., thus: $K = Hb \times 100/Ev$, where K = concn., Hb = g. hemoglobin per 100 cc., and Ev blood cell vol. in %. In splenectomized animals the regeneration of the blood in rarefied air proceeds slower than in non-operated animals. The erythrocytes also become larger in the splenectomized animals just as in the case of pernicious anemia. Injections of spleen pulp have a favorable influence on the blood-cell production. S. M.

Avitaminosis and adrenals. II. Behavior of pigeons suffering from B-avitaminosis towards adrenaline and choline. ERNST SCHMITZ AND H. J. POLLACK. Physiol. Inst., Breslau. *Biochem. Z.* **195,** 428–41(1928); cf. *C. A.* **21,** 2296.—Feeding of whole suprarenal bodies to pigeons fed on rice prevents the onset of suprarenal hypertrophy which is not brought about by administering adrenaline. The effect of the whole suprarenal gland cannot be attributed either to choline or to the adrenaline. S. MORGULIS

Studies on the metabolism of the placenta. I. EISUKE ISHIKAWA. Inst. für exptl. Pathol., Univ. Wien. *Biochem. Z.* **195,** 469–74(1928).—The incubation under strictly sterile conditions either of rabbit placenta or of its ext. under aerobic or anaerobic conditions results in an increase of reducing substances (glycogenolysis). The addn. of glucose has no effect on this process, but levulose or dihydroxyacetone does accelerate and increase the glycogenolysis. The placenta pulp or ext. under sterile conditions does not affect the levulose or dihydroxyacetone. Under aerobic conditions there is generally an initial diminution of lactic acid, but in other cases there is no alteration. In later phases of the process there is an increase in lactic acid. Under anaerobic conditions, however, there is never an initial loss. The addn. of dextrose or levulose has no noticeable influence on the amt. or rate of lactic acid formation. S. MORGULIS

Potassium in the blood of normal individuals. Experiments on the Kramer-Tisdall method for potassium determination. HELGI TOMASSON. Staatsirrenanstalt Vordinborg, Dänemark. *Biochem. Z.* **195,** 475–85(1928).—The Kramer-Tisdall method for K gives unreliable results in the presence of appreciable quantities of NH_3. Serum, must, therefore, be worked up immediately while still fresh. Added KCl is not satisfactorily recovered from serum, the results being generally too low. In 13 normal persons 20.3 mg. K per 100 cc. serum was found (17–23 mg. extreme variations). The range of variation for the same individual is of the same magnitude. Sudden muscular work does not affect the serum K. In women a rise in the K concn. is found in the early stage of menstruation. S. MORGULIS

The influence of thyroid substances on the fat metabolism. I. ABELIN AND P. KÜRSTEINER. Physiol. Inst., Bern. *Biochem. Z.* **198,** 19–46(1928).—The large loss of fat after the administration of thyroid substance is chiefly due to a sp. effect on fat metabolism. In animal expts. it was shown that already 24–72 hrs. after feeding thyroid there was considerable loss of fat although the oxidation was only slightly increased. The greatest loss occurs in the striated muscles, then in the liver and lungs. The metabolism of fat is affected in the same manner as that of carbohydrate or protein, and manifests itself chiefly in an inability of the cells to resynthesize these substances from the foodstuffs. The intensity of the thyroid action increases as the fat is diminished. On the contrary, early administration of abundant fat inhibits the utilization of the hormone, the liver retaining its glycogen-forming ability, the basal metabolism not being so greatly increased and the organs not losing so much of their fat depots. The influence of the fat is favorable only in the initial stages of hyperthyroidization but in later stages it actually exerts an injurious effect. However, the antagonism between the 2 substances is obvious at all times, and the excess of either fat or thyroid diminishes the physiological action of the other. After the administration of thyroid substance the liver becomes both fat and glycogen poor, but under the influence of adrenaline the glycogen-forming ability of the liver is partly restored. Fat is not only a source of energy and vitamins but also a substance with important antitoxic properties and a regulator of thyroid function. S. MORGULIS

The spleen as regulator of the amino acid balance of the blood. I. Effect of

spleen extirpation on the amino acid content of blood, red blood cells and plasma. LIDIA TUTKEVICH. Ukrnauka, Charkow. *Biochem. Z.* **198,** 47–59(1928).—Intravenous injection of amino acids causes at first (10 min.) a lowering of the amino acid content of the red blood cells. Splenectomy, on the contrary, results in a failure of this preliminary reaction of the cells and the injection of amino acids then causes invariably a rise in the amino acid content of both cells and plasma. The spleen is responsible for the ability of the spleen to adsorb amino acids which can be easily demonstrated *in vitro*. Following splenectomy, the *in vitro* adsorption capacity of the cells from dogs and rabbits completely disappears or is diminished. The red cells, when they adsorb a certain amt. of amino acid, lose a corresponding quantity of non-protein N to the plasma. The spleen plays an important function in the retention or accumulation of amino acids either of endogenous or exogenous origin. **II. Effect of denervation of the spleen on the amino acid content of the blood, red blood cells and plasma.** *Ibid* 60–4.—The relative vol. of red cells and plasma diminishes in animals with denervated spleens as well as in splenectomized animals. Following denervation of spleen the blood amino acid content decreases at first but increases subsequently whereas in splenectomized animals the amino acid content remains low. The difference is entirely due to the cellular elements since the amino acid content of the plasma remains unchanged. Injection of amino acids causes in animals with denervated spleens an increase in the amino acid content of the red cells, because the spleen is physiologically isolated and does not take up any of the substance. S. MORGULIS

Metabolism of walking on a plane surface. A. HIETANEN, M. NIKKINEN, H. NYYSSÖLÄ AND G. STERNBERG. Univ. Helsingfors. *Skand. Arch. Physiol.* **54,** 145–8 (1928).—Oiling the tread-mill caused an increase in metabolism which in 2 exptl. subjects ranged from 51.1 to 72.8%. S. MORGULIS

The metabolism of liver tissue from rats of different ages. J. A. HAWKINS. Rockefeller Inst. *J. Gen. Physiol.* **11,** 645–7(1928).—These expts. were undertaken to det. whether there is a difference in respiration and aerobic glucolysis in livers of rats of different ages. The results show that no difference occurs in livers of rats 22 months, 1 yr. or 3–21 days old. Practically no glucolysis takes place in the livers of old and normal adult rats, but a certain amt. in those of very young rats. Livers of young rats therefore have the same type of metabolism as embryonic tissue. The glucolytic activity of a tissue seems to be a function of the growth rate. Cf. Murphy and Hawkins, *C. A.* 20, 445; Hawkins, *C. A.* 20, 3506. C. H. RICHARDSON

Significance of the chemical composition of the secreting and dry mammary gland to milk secretion. J. W. GOWEN AND E. R. TOBEY. Rockefeller Inst. and Maine Agr. Expt. Station. *J. Gen. Physiol.* **12,** 123–8(1928).—Cows producing up to 30 lbs. milk at each milking have the lactose equiv. of this milk in the udder when milking commences. The av. excess lactose present in the udder after deducting the amt. to be contained in the milk is 2.1 lbs. which is equiv. to the milk retained in the udder when the cow is dry. No sugar is found in the udder in the quiescent state. The udder contains a large excess of fat, ash and N in proportion to that necessary for milk formation. The excess of udder lactose over milk lactose is much less. Lactose is formed from some blood constituent, probably glucose, as needed for milk formation. The dry udder builds up a fat reserve having a Reichert-Meissel no. quite different from that of butter fat. It contains no sugar and less ash but its N content is like that of the secreting gland. C. H. RICHARDSON

Basal secretion of the stomach. I. Influence of residues in the small and large intestine. CHIH-TEH LOO, HSI-CHUN CHANG AND R. K. S. LIM. Peking Union Med. Coll. *Chinese J. Physiol.* **2,** 259–78(1928).—Pavlov- and Heidenhain-pouch dogs were given glass and silver beads with their meals. The glass beads were all expelled within 2 days and the silver beads within 3 days. When different-colored glass or different-shaped silver beads were given on successive days, some mixing of the daily quota of beads usually occurred and this was found by x-ray examn. to take place chiefly in the colon. Ba was added to the meal in a certain series of tests. No relationship could be established between the rate of progress of food residues through the intestines, as judged by bead or Ba observations, and the basal gastric secretion. Neither acceleration of the movement of the intestinal contents by the action of paraffin oil, nor retardation by partial ligation of the intestine was followed by any const. change in the basal secretion. L. W. RIGGS

Chloride metabolism of the vivi-perfused stomach. C. L. HOU, TSANG-GI NI AND R. K. S. LIM. Peking Union Med. Coll. *Chinese J. Physiol.* **2,** 299–304(1928).—The av. basal Cl intake of the vivi-perfused stomach is 0.029 mg. per g. of gastric mucosa per min. The basal Cl intake is thus relatively low, but it is higher than can be accounted

for by the quantity of Cl in the basal secretion. After the injection of histamine (to induce an active secretion) the Cl intake of the stomach increases 2 to 15 fold. The summit of this increase occurs earlier than that of the Cl secreted as acid in the gastric juice, indicating that the active oxyntic cells take up an excess of Cl, but later as the secretion subsides, the intake may fall below the output. At this point Cl may be returned to the venous blood. L. W. Riggs

Lipoid metabolism of the stomach and its relation to the mitochondria-Golgi complex. Schmorl M. Ling, A. C. Liu and R. K. S. Lim. Peking Union Med. Coll. *Chinese J. Physiol.* 2, 305–28(1928).—Both basal and active gastric juice contain lipoid, of which about 10% is phospholipin. The lipoid output increases with the secretion. Apparently the non-P lipoid of the juice is extruded chiefly by the oxyntic and the phospholipin by the peptic cells. The basal gastric mucosa contains not more than 3% of lipoid, of which less than half is phospholipin. After 6 hrs. of activity the total lipoid content is unchanged, but the phospholipin fraction increases as do the I nos. of both phospholipin and non-P lipoid fractions. Since in general mitochondria increase and Golgi element decreases after activity, the increase of phospholipin may be assigned to the former and non-P lipoid to the latter. It is possible that as the fatty acids of the mitochondrial phospholipins become more unsatd. during activity, they dissociate, sepg. from the phospholipin mol. and forming Golgi material. The Golgi lipoid may be discharged with the secretion, oxidized or resynthesized. L. W. R.

Further observations on tryptophan and the thyroid gland. Hsi-Chun Chang and Wen-Chao Ma. Peking Union Med. Coll. *Chinese J. Physiol.* 2, 329–36(1928).—The morphology of the thyroid glands of albino rats varies with body wt. The mitochondria vary in no. and shape according to the functional state of the thyroid glands. Tryptophan appears to have no sp. morphological influence on the thyroid gland. From evidence so far accumulated tryptophan is not related to the thyroid hormone. L. W. Riggs

Normal variations of blood chemical constituents in Chinese. Schmorl M. Ling. Peking Union Med. Coll. *Chinese J. Physiol. Report Series 1928*, No. 1, 119–22.—The lower limits of non-protein and urea N for the Chinese are slightly lower and that of sugar is much lower than the American standards, while uric acid and creatinine show practically no difference. The concns. of inorg. salts are the same in both races, except the max. figure for inorg. P of serum, which is slightly higher in the American records. The cholesterol content of the plasma is definitely low, although the fat content shows only a low min. The max. for fibrinogen, albumin and total protein of the plasma are low for the Chinese. The same is true of blood gases. The differences herein noted are slight and may disappear when more observations are available. L. W. Riggs

Nitrogenous metabolism in South China. San-Yin Wong. Univ. Hongkong. *Chinese J. Physiol. Report Series 1928*, No. 1, 123–8.—Analyses of the urines of 12 medical students in the Univ. of Hongkong showed the av. total N only a little lower than the European standard, but about $^1/_3$ higher than that of the Peking students. The urea N as percentage of the total N is lower than the European standard and about the same as that of Peking students. The NH_3 N as percentage of the total N is a little higher than the European standard but considerably lower than that of Peking students, due probably to a dietetic factor. A high creatinine output indicates a high metabolism of the tissues. The abnormally high value for uric acid N may be attributed to the excessive drinking of tea and coffee. L. W. Riggs

Metabolism of the isolated ovary. Alexandre Lipschütz and Serge Vesnyakov. *Compt. rend. soc. biol.* 99, 535–6(1928).—If the ovary of the guinea pig is isolated without a nutritive medium it continues to absorb O even at the temp. of melting ice. The intensity of the metabolism under these conditions is 1/15 to 1/30 of that at body temp., and may remain nearly const. for several days. If the isolated ovary is exposed for a few min. to temps. below 0°, then is removed to room temp., it will have a respiration nearly normal for a few hrs. and then cease to respire. L. W. Riggs

Effect of thyroidectomy and of parathyroidectomy on the functioning of the hemato-encephalic barrier. L. Stern, L. G. Belkina and A. O. Slatowierow. *Compt. rend. soc. biol.* 99, 536–7(1928); cf. *C. A.* 21, 3973.—Ablation of the thyroid in cats was followed by no apparent change in the hemato-encephalic barrier. After 10 days the passage of trypan blue from the blood into the cerebrospinal fluid was observed but NaI and $Na_4Fe(CN)_6$ did not pass. Simultaneous ablation of thyroid and parathyroid or of parathyroid alone was followed within 2 days by the passage of both colloids and crystalloids, which had been injected into the blood, into the cerebrospinal fluid. L. W. Riggs

Effect of blockage of the reticulo-endothelial apparatus on the functioning of the

hemato-encephalic barriers. L. Stern, G. N. Kassil and E. S. Lokshina. *Compt. rend. soc. biol.* **99**, 538–9(1928).—Acute blockage of the reticulo-endothelial app. by 20 cc. of 2% India ink per kg. diminished the resistance of the hemato-encephalic barrier to the passage of Bi. Chronic blockage by injection of India ink during 6 to 7 days has the same effect as acute blockage but more pronounced. Of the various substances, colloidal and crystalloidal, injected into the circulation only Bi passed into the cerebrospinal fluid following the blockage of the reticulo-endothelial system.

L. W. Riggs

Variation of the blood sulfur content in the course of asphyxia. Léon Binet and Réne Fabre. *Compt. rend. soc. biol.* **99**, 577–8(1928).—In 6 dogs acute asphyxia prolonged during 5 min. caused an increase of from 8.22 to 57.37, av. 21.88% in the total S in the arterial blood plasma. This increase is in the neutral S. The sulfates are diminished.

L. W. Riggs

Elimination of nucleoproteins by the bile. P. Carnot and Z. Gruzewska. *Compt. rend. soc. biol.* **99**, 598–600(1928); cf. *C. A.* **21**, 2332.—The const. presence of cholenucleins in the bile indicates a particular function of the liver. The vesicular bile on account of its concn. during its sojourn in the gall-bladder is richer in cholenucleins, biliary acids and pigments. After treatment with large doses of $NaHCO_3$ the cholenucleins diminish to a limit which varies between 0.3 and 0.4%. **Phosphorus content of the cholenucleins.** *Ibid* 600–1.—In the dog the quantity of P eliminated in cholenucleins varies between 8 and 10 mg. per 100 cc. of bile.

L. W. Riggs

The detoxicating hormone of the liver (Yakriton). VI. Proposal of quantitative estimation of hunger injury. Akira Sato. *Tohoku J. Exptl. Med.* **11**, 265–71(1928); cf. *C. A.* **21**, 1141, 1494.—S. emphasizes that the title "quant. estn. of hunger injury" does not mean quant. estn. of some chem. constituent of the body during hunger, but a "quant. detn. of hunger injury itself." The scale selected is the no. of units of Yakriton. Ten rabbit-ammonia units (R. A. U.) raise the rabbits of class *b*(R*b*) to those of class *f*(R*f*) provided they are both feeding. The interval between R*b* (of ordinary detoxicating power) and R*f* (of very active detoxicating power) may be defined as 10 R. A. U. A R*b* remains, when it is made to fast, to be of the class *b*, thus apparently to be of the same detoxicating power as when fed, but 10 R. A. U. does not raise it to class *f* any more, and many more units will be required according to the no. of days of fasting. The interval between class *f* and class *b* has thus become much larger. A R*f* becomes, when it is made to fast for some time, to be R*b*, but then it remains R*b*. Thus it may seem that a R*f* will, when made to fast, come down as far as 10 R. A. U. and stays there in spite of prolonged fasting. But now many more units than 10 R. A. U. will be required to raise it to the original class *f*, and the no. of units is larger as the no. of days of fasting is increased. Accordingly the hunger injury of an apparently healthy animal can be quant. detd. if it is expressed in the no. of units of Yakriton. **VII. Preparation of Yakriton with further experience of potency testing.** *Ibid* 272–6.—An aq. ext. of ox liver is evapd. to a sirup and is extd. with a large amt. of alc.; the alc. ext. is concd. and dazol is added. After shaking the dazol is collected on a filter and is washed with alc. The dazol is now extd. with water, the aq. ext. is evapd. to a small amt. which is extd. with Et_2O. The Et_2O ext. is evapd. to dryness and is dissolved in water, the soln. is repeatedly treated with toluene and then decolorized with charcoal. The soln. thus prepd. is again evapd. to dryness, the residue is dissolved in alc., this alc. soln. is evapd. to dryness and the residue dissolved in water. The soln. thus prepd. is colorless, neutral and does not give the biuret reaction. It can be boiled without loss of potency and it keeps indefinitely. It does not contain any trace of histamine-resembling substances. It is readily sol. in Et_2O, fairly sol. in alc. and rather insol. in water. Further potency tests were made and the following conditions for the standardization were established: (1) Rabbits used for potency testing (both control and Yakriton animals) should be of class *b* at least at 3 successive liver tests made within several days of the potency testing. The animals should not lose wt. during these days. (2) On occasion of potency testing, at least 2 of 3 control animals should become *b* by the intraperitoneal injection of NH_4Cl, while the third rabbit may become *b*, *c*, *d*, *a*, *e* or even *f*. As to Yakriton animals, it is not satisfactory that only 3 from among the group used become *f*. The testing must be continued until 3 *consecutive* rabbits will have turned out *f*. The amt. of ext. used in these last 3 animals contains full 10 R. A. U. of Yakriton per kg. of body wt. (3) A guinea pig should remain without any perceptible symptom, if Yakriton is injected intracardially at once in 100 R. A. U. per hectogram of body wt. **VIII. How to select individuals certain of anaphylactic shock.** Kazue Suzuki and Akira Sato. *Ibid* 277–81.—The liver test devised by Sato and Sakurada was utilized for distinguishing the animals apt to die from anaphylaxis from those more or less refractory. The

method consists in putting sensitized animals to the detoxicating liver test before the final intoxicating injection. A rabbit of class *f* will generally develop a fatal or grave anaphylactic shock while one of class *b* will be more or less refractory. Control animals should be selected from among animals of the same or nearly the same class. **IX. Effect of Yakriton on anaphylaxis.** KAZUÉ SUZUKI. *Ibid* 282–92.—Yakriton, subcutaneously injected repeatedly for several days previous to the intoxicating injection of foreign protein, will make a refractory rabbit so strongly reactive to anaphylaxis, as to cause a fatal shock. Yakriton, subcutaneously injected in a rather large amt. 5 min. before the intoxicating injection of foreign protein, will cause a rabbit which would otherwise be sure of an anaphylactic shock, to be refractory to anaphylaxis Thus by use of Yakriton it is possible to make a given rabbit, very sensitive to anaphylaxis, to be immune to anaphylactic shock, and to cause another rabbit, refractory to anaphylaxis, to be so sensitive to the reaction that the shock is fatal. L. W. R.

Simultaneous determination of the epinephrine liberation, the sugar content and the coagulation time of blood in non-fastened, non-anesthetized dogs after hemorrhage. SHIDZUKA SAITO, BUNKICHI KAMEI AND HIROSHI TACHI. *Tohoku J. Exptl. Med.* **11**, 205–17(1928).—The numerical results fill 10 pages. The max. of the blood-sugar content after bleeding appeared earlier than that of increased epinephrine discharge, or simultaneously. In half of the cases there was a remarkable shortening of the time of blood coagulation. **Relation of the augmented epinephrine secretion after hemorrhage in dogs to the simultaneous occurrence of hyperglucemia.** HIROSHI TACHI AND SHIDZUKA SAITO. *Ibid* 218–32.—Adrenaline was introduced into a vein of a normal dog at a rate, which was chosen to imitate approx. the rate of epinephrine output after hemorrhage of about 1/6 or 2/6 of the total blood vol. The results justify the conclusion that the augmented epinephrine output from the suprarenal bodies after hemorrhage plays at least a highly important role in causing hyperglucemia after hemorrhage.

L. W. RIGGS

Ovarian hormone. E. C. DODDS. Univ. of London. *Lancet* **1928**, I, 1107–10; cf. *C. A.* **21**, 3227.—A highly potent prepn. is described which will produce estrus, cause great enlargement of the genital tract, induce premature puberty and cause abortion and possibly premature labor. It is prepd. as follows. The placenta is hydrolyzed with $Ba(OH)_2$ and the supernatant fluid extd. with C_4H_9OH. The alc. is evapd. off and the residue dissolved in H_2O and this soln. extd. with ether. All protein is removed by shaking this ethereal soln. with HCl. The ethereal soln. is then heated with a small amt. of $Ba(OH)_2$ to render sapon. complete. The ppt. is filtered off and excess of Ba removed by addn. of dil. H_2SO_4. The final H_2O-clear soln. contains the active material. Clinical investigations of this material, which has been carefully standardized on animals, is just about to begin. F. B. SEIBERT

The specific gravity of the blood. Experimental evidence of difference in weight of the blood of the right and left ventricles of the heart. R. J. TERRY AND G. A. SEIB. *Anat. Record* **36**, 279–92(1927).—The blood of the common carotid artery, and perhaps that of the left ventricle, is more dense than is the blood of the right ventricle. Detns. made in fasting cats under urethan anesthesia under conditions providing for normal respiration, pulse and blood pressure gave an av. sp. gr. of 1.0488 for the blood of the right side, of 1.0504 for that of the left side of the heart. The difference between the two bloods was somewhat greater in male animals. G. H. S.

A new hormone of the circulation and its action. III. EMIL K. FREY AND HEINRICH KRAUT. Charité Surg. Clinic, Berlin, and Bayer's Acad., München. *Arch. exptl. Path. Pharm.* **133**, 1–56(1928).—From the urine a substance can be recovered and purified which functions as a hormone markedly influencing the circulation. With effective doses the increase in pulse rate is (av.) 6%, although under certain circumstances the acceleration may be much greater (double the normal rate). The amplitude of the beat is also increased, in some cases as much as 9-fold, the effect persisting for from 0.5 to 10 min. after a single injection. With repeated injections the period is protracted. Immediately after the injection rate of flow is always definitely diminished, but very quickly (20 secs.) the normal vol. is restored and often exceeded. Coincident with the reduction in vol. there occurs a fall in blood pressure (33%) which also is transitory. Apparently the active agent acts through an effect on the heart muscle rather than through the nervous mechanism. With hearts whose action is impaired the hormone appears to exert a regulating influence. Not only are these effects observed when the hormone is injected into the intact animal, but also when it is added to the perfusion fluid used with isolated hearts. This is true of mammalian, not frog, hearts, for while the latter may react to raw urine the purified prepn. is without effect. The hormone exerts a direct effect upon the walls of the capillaries, resulting first in a vasoconstriction fol-

lowed by an increased dilatation of the vessels of the lung, brain, skin and muscles. The vessels of the other organs show a reduction in vol. corresponding to the fall in blood pressure. Intravenous injections of the hormone reduce the blood pressure of the systemic circulation and increase the pressure within the pulmonary system. Upon the non-narcotized animal the hormone has little if any influence upon the respiration, but in the narcotized it causes some slight increase in the respiratory rate. Acting upon kidney function the injected hormone causes an initial fall in secretory activity followed by an increased flow, but the effects are considerably modified by the dosage. When placed in contact with smooth muscle (intestine, uterus) the hormone causes a histamine-like increase in tonus. The characteristic effects are intensified and prolonged by the addn. of small amts. of Ca salts. The hormone is inactivated both *in vivo* and *in vitro* by blood; serum is less effective and less const. in its action. The inactivating agent in blood is a definite substance, very unstable and sensitive to heat and acids. Apparently the active principle of the hormone cannot be identified with any of the known substances which exert similar effects. It can be demonstrated to be present in the blood.
G. H. S.

Psychic stimulation of the posterior lobe of the hypophysis. H. Hoff and P. Wermer. Univ. Wien. *Arch. exptl. Path. Pharm.* **133**, 97–102(1928).—In dogs which are excited by the sight of cats there occurs a considerable increase in the secretion of pituitrin. This explains the inhibition of diuresis. Small doses of luminal or trichloroisobutyl alc. prevent the increased output of pituitrin. G. H. S.

Function of renal tubules. Tahira Fujita. Tokyo Imp. Univ. *Proc. Imp. Acad.* (Japan) **4**, 415–7(1928).—Chloride, which is eliminated practically only from the glomeruli with H_2O, is partly reabsorbed in the tubules with H_2O; while SO_4 and other urinary constituents, such as K, Ca, Mg, PO_4, uric acid and urea, which are eliminated, both from the glomeruli and the tubules as far as any satisfactory demonstration is concerned, are not reabsorbed in the tubules. C. J. West

The occurrence of lead in the egg of the domestic hen. Wilfrid B. S. Bishop. *Med. J. Australia* **1**, 480–8(1928).—The Nessler method for the detn. of Pb in an alk. soln. using a new technic for the detn. of small quantities of Pb is described, and the accuracy of the method detd. Pb found: shell, 0.1 to 1.6 mg. per 100 g. wet material; yolk, 0.2 to 1.0 mg. per 100 g. wet material; white, 0.12 to 0.48 mg. per 100 g. wet material. R. C. Willson

The occurrence of molybdenum in the egg of the domestic fowl: A preliminary communication. Winifred R. Mankin. *Med. J. Australia* **2**, 87(1928).—The method used is a modification of that used by Hall (*C. A.* **16**, 2461) and by Koppel (*C. A.* **14**, 1501). The material is ashed at a fairly low temp. in porcelain and transferred to Pt. Previous expts. have shown that extn. with HCl or *aqua regia* was not satisfactory. The ash is treated with NH_4NO_3 and then with a mixt. of NH_4NO_3 and Na_2CO_3 (1:2). After cooling, an aliquot is dissolved in a min. quantity of H_2SO_4 and made just alk. with NaOH, the total vol. being less than 5 cc. From 0.3 to 0.5 g. of solid K xanthate is dissolved in the soln. and a few drops of 10% H_2SO_4 added, the tube being agitated after the addn. of each drop, till a purple color develops. The av. Mo content of the whites of 18 eggs is 0.01 mg. per 100 g. egg white, the color having the same intensity as that given by 0.01 mg. of Mo as $(NH_4)_2MoO_4$. No definite results for egg yolk have been obtained. No purple coloration was given when known mixts. were used contg. Fe, Sr, Mg, Pb, K, Cr, Co, I, B, U, Ni, As, Hg, V, Br, Cl and PO_4, SO_4 and NO_3.
R. C. Willson

The effect of iodine on milk secretion. E. Maurer and H. Ducrue. *Münch. med. Wochschr.* **75**, 249–51(1928).—Tests were made to det. possible changes in milk compn. due to a single large dose of I. A nurse was tested 3 days for the quantity of milk secreted daily. Then 0.6 g. KI was given daily for 7 days. The quantity of excreted milk was not changed, but the I content far exceeded the normal 2.6γ%. During the first 3 days 15% of the administered I was eliminated. The milk participated in the I output. During the last 5 days, the I content of the milk was above normal. The quantity of fat-free dry mass was slightly increased; this is attributed to an increase in protein content. The blood sugar content was increased. The increase in ash was most marked and indicates that the addn. of I to the food stimulates the elimination of mineral matter in the milk. Fat was decreased. There is reason to believe that fat decrease runs parallel with the increase in I dosage. R. C. Willson

G—PATHOLOGY

H. GIDEON WELLS

Survey on the metabolism experiments on carcinoma tissue. E. HAAGEN. *Arb. Reichsgesundh.* 59, 429–43(1928). G. SCHWOCH

Effect of kidney on blood regeneration in pernicious anemia. W. S. MCCANN. *Proc. Soc. Exptl. Biol. Med.* 25, 255–8(1928).—Two patients with pernicious anemia, who were fed diets contg. 250 g. of kidney daily, were improved after 17 and 27 days of the treatment. The blood counts showed marked regeneration. The relative values of kidney and liver feeding can be detd. only on comparison of a long series of cases. C. V. B.

The adaptation in vitro of diphtheria bacillus to specific antitoxin. CLAUS W. JUNGEBLUT. Stanford Univ. *Proc. Soc. Exptl. Biol. Med.* 25, 427–9(1928).—Two diphtheria strains cultivated in a specific antitoxin medium underwent complete loss of toxin production. The atoxic filtrate of one strain, if given in a single subcutaneous dose of 2 cc., failed to induce the formation of antitoxin in guinea pigs within the period of 3 weeks, as measured by intracutaneous tests. Flocculation reactions were carried out by combining the atoxic filtrates of the 2 adapted strains with diphtheria antitoxic serum. The atoxic filtrates flocculated much less than the corresponding control toxins. However, some definite flocculation did occur with these atoxic and non-antigenic filtrates. The evidence so far suggests that these atypical properties acquired during exposure to specific antitoxin are transitory. C. V. B.

Passive sensitization with Maignon's fraction of anaphylactic blood. W. H. MANWARING, J. L. AZEVEDO AND H. C. TORBERT. Stanford Univ. *Proc. Soc. Exptl. Biol. Med.* 25, 431–2(1928).—Maignon's pptn. and extraction technic was applied to 9 canine anaphylactic bloods and to emulsions of 6 hypersensitive livers. Eleven of the products obtained were wholly inert. Two of the blood products and 1 liver product gave slight passive hypersensitiveness and 1 blood product gave a very severe anaphylactic phenomenon, which, however, had not the symptomatology and autopsy findings of a typical anaphylaxis. It is probable that this was an atypical hypersensitive phenomenon of unknown nature. C. V. B.

A simplified serological test for tuberculosis. ADELAIDE B. BAYLIS. Columbia Univ. *Proc. Soc. Exptl. Biol. Med.* 25, 482–3(1928).—A test for tuberculosis is described, based on the Vernes principle of a periodic sinusoidal curve of ppt. It lacks the delicacy of the Vernes technic, but is capable of giving diagnostic information and requires only inexpensive equipment. C. V. B.

Difference in susceptibility of mice and rats to experimental production of amyloidosis. BALDWIN LUCKE AND L. A. MARKLEY. Univ. of Penn. *Proc. Soc. Exptl. Biol. Med.* 25, 642–6(1928).—Amyloidosis was produced in 75% of mice by injections of alkali caseinate solns., while entirely neg. results were obtained in rats. The mice suffered in health from the injections, while the rats thrived. Possibly the breaking down of tissue proteins in the rats was not sufficiently severe to lead to amyloid formation. C. V. B.

Studies on anaphylaxis with the products of peptic digestion of protein. II. KARL LANDSTEINER. Rockefeller Institute. *Proc. Soc. Exptl. Biol. Med.* 25, 666–7(1928).—Animals sensitized with peptic digestion products of egg globulin were more sensitive to these than to unchanged globulin and *vice versa*. After pptn. with trichloroacetic acid and alc. the resulting substance was much more toxic for the guinea pigs sensitized with the digested material than for those sensitized with globulin. Similar results were obtained by sensitizing with digested heat-coagulated egg globulin. C. V. B.

Experimental ulcer of the colon in rats. W. M. BALDWIN. Albany Medical College. *Proc. Soc. Exptl. Biol. Med.* 25, 679–81(1928).—After several subcutaneous injections of a soln. of mercurochrome 220 soluble into white rats, examn. at autopsy revealed staining of the tissues with the dye, marked histologic changes in the kidneys and colitis and enteritis. In addn. a const. ulcer was identified upon the median wall of the ascending colon, directly cephaled to the iliocecal valve. A theory as to the mechanism of this ulcer production is given. C. V. B.

Preparation of relatively stable emulsions with Kahn antigen base. B. S. KLINE. Mt. Siani Hosp., Cleveland. *Proc. Soc. Exptl. Biol. Med.* 25, 689–92(1928).—Kahn antigen base when concd., chilled and used according to a formula described yields thoroughly satisfactory emulsions that retain their antigenic properties undiminished in pptn. tests for syphilis for 3 days. These emulsions are superior to Kahn antigen dilns. in tests made at room temp. in giving no false clumping. Because more cholesterol

may be dispersed in a given total by the new formula, it is possible to make the emulsions more sensitive, yet no less specific, than Kahn antigen dilns. from the same ext. C. V. B.

Effect of liver extract on erythrocytes and reticulocytes in normal individuals. CHARLES H. WATKINS, RICHARD JOHNSON AND HILDING BERGLUND. University Hosp., Minneapolis. *Proc. Soc. Exptl. Biol. Med.* **25**, 720–3(1928).—Liver ext. in normal individuals, as in pernicious anemia, brings about an immediate release of red blood cells into the circulating blood. In the normal individual the maturation of the cells is complete and the release rapid; in pernicious anemia the maturation is retarded, discharge of incompletely matured cells occurs and precedes the discharge of fully matured ones; the process as a whole is prolonged. C. V. B.

Effect of intravenous bacterial filtrates on skin tests and local infections. FRANKLIN M. HANGER, JR. Presbyterian Hosp., N. Y. *Proc. Soc. Exptl. Biol. Med.* **25**, 775–7(1928).—When filtrates of strains of *B. lepis epticum* and other Gram-negative strains are injected intravenously, the reaction is quite different in the allergic and non-allergic rabbit. The symptoms are given in detail. C. V. B.

Variability in distribution of allergic skin response. H. L. ALEXANDER. Washington Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 800–3(1928).—When a given amt. of allergen is injected successively at various sites in the skin, there is a marked variation in the size of the resulting wheals. The responses on the back and abdomen tend to be larger than elsewhere. From similar results with injections of histamine into the skin of dogs, it is conceivable that the variations in allergic wheal formation in human skin are due to lack of uniform response on the part of the skin capillaries to the same stimulus, rather than to an uneven distribution of antibodies in the skin cells. C. V. B.

Rapid stimulation of hemoglobin synthesis in secondary anemias after feeding fetal calf liver. HILDING BERGLUND, CHARLES H. WATKINS AND RICHARD JOHNSON. University Hosp., Minneapolis. *Proc. Soc. Exptl. Biol. Med.* **25**, 814–7(1928).—A procedure to accelerate the hemoglobin synthesis in secondary anemia through the feeding of fetal calf liver has been carried out successfully. C. V. B.

Significant difference in response of pernicious anemia to fetal calf and beef liver feeding. HILDING BERGLUND, CHARLES H. WATKINS AND RICHARD JOHNSON. University Hosp., Minneapolis. *Proc. Soc. Exptl. Biol. Med.* **25**, 834–5(1928).—An instance is presented of complete maturation of erythrocytes during the whole of an induced rapid remission in a typical severe case of pernicious anemia. This was produced by feeding powdered fetal calf liver. Beef-liver ext. had produced a transitory slight increase in erythrocytes, reticulocytes and megaloblasts, and was unsuccessful in producing a complete remission. C. V. B.

Statistical significance of erythrocyte counts during responses to liver extract in normal individual. HILDING BERGLUND, CHARLES H. WATKINS AND RICHARD JOHNSON. Univ. of Minnesota. *Proc. Soc. Exptl. Biol. Med.* **25**, 835–8(1928).—Erythrocyte counts were made on a normal man at 3-hr. intervals during the day before liver ext. was fed and during 6 days' feeding of Cohn-Minot liver ext. The differences of the mean counts at different times of the pre-liver day were found to be statistically insignificant. On the liver-feeding days the differences showed a high statistical significance, and the liver ext. appeared to have a marked effect on the counts. A series of reactions occurred periodically in 24 hrs. A strong factor appeared to be present tending towards increasing the concn. of circulating erythrocytes; this factor evidently checked by a force aiming to preserve a lower level of erythrocytes. The latter force appears to gain on the former, leaving the person with a lower level at the end of the expt. than at the beginning. C. V. B.

Composition of antigen-precipitin precipitate. HSIEN WU, LAN-HUA CHENG AND CHEN-PIEN LI. Peking Union Med. College. *Proc. Soc. Exptl. Biol. Med.* **25**, 853–5 (1928).—The antigen-precipitin ppt. probably has a const. compn. and the reaction between the antigen (*a*) and the precipitin (*p*) is probably chem. and not merely phys. or colloidal. The assumption that the ppt. contains the *a* and *p* (protein) and no other protein seems justified; otherwise it would be hard to explain the constancy of the hemoglobin content of the ppt. C. V. B.

Comparative toxicity of sera of arterial and venous blood. A. LUMIÈRE AND R. H. GRANGE. *Compt. rend.* **186**, 1064–6(1928).—The toxicity of human and dog's blood sera when injected into guinea pigs is due not to the presence of a poison but to the flocculation of the plasma colloids by those of the heterogeneous serum. The toxicity is lost either by keeping the serum at the ordinary temp. for several days or by exposure to a vacuum. This is due to the loss of CO_2, since, in agreement with this view, the injection of serum prepd. from the venous blood of a dog causes violent

convulsions, quickly followed by death, whereas the injection of the same dose of serum prepd. from arterial blood has very little or no effect. B. C. A.

Occurrence and detection of arginine in cystinuria. F. A. Hoppe-Seyler. *Deut. Arch. klin. Med.* **154,** 97–106(1927).—Arginine was detected in the urine in cystinuria by pptn. with flavianic acid, decompn. of the ppt. with $Ba(OH)_2$, purification with phosphotungstic acid, and treatment of the filtrate with $CuCO_3$, forming *d*-arginine-Cu nitrate. B. C. A.

Iodine problem and exophthalmic goiter prophylaxis from the point of view of agricultural chemistry. K. Scharrer. *Münch. med. Wochschr.* **74,** 1788–90(1927).—Administration of NaI in the fodder of goats and cows considerably increases the I content of the milk and blood, and larger quantities increase the yield of milk. The milk obtained after moderate administration of I is readily tolerated by infants. Application of fertilizers contg. I considerably increases the I in plants. B. C. A.

Azotemia and Becker's xanthoproteic reaction in nephritics. Flamminio Ricci. Univ. Rome. *Arch. farmacol. sper.* **45,** 153–72(1928).—The retention of phenols and aromatic hydroxy acids in the blood as shown by Becker's xanthoproteic reaction is probably a better measure of renal insufficiency than is the urea content of the blood. No strict quant. relationship exists between the phenol concn. of the blood and the seriousness of the kidney lesions, but in general a high phenol content accompanies acute renal insufficiency. On the other hand, azotemia and phenol concn. bear no definite relationship to each other, since low urea concn. with high phenol may be observed, and *vice versa*. In testing kidney function 1 g. of urea administered orally is a useful diagnostic agent. With acute renal insufficiency azotemia is then observed often accompanied by increased intensity of the xanthoproteic reaction, while with mild cases the resulting diuresis diminishes the urea content of the blood. A. W. Dox

The nitrite reaction for diagnosis of infections of the urinary tract in obstetrics and gynecology. F. d'Aprile. Univ. Rome. *Arch. farmacol. sper.* **45,** 177–86 (1928).—The nitrite reaction (red color with *p*-$H_2NC_6H_4SO_3H$ and α-$C_{10}H_7NH_2$) in urine may be of value for detecting bacterial infections of the urinary tract. In case the reaction is neg. a control test should be made after adding a few drops of $NaNO_2$ soln. and incubating 1–2 hrs. at 37°. If the reaction is pos. a bacterial infection is practically certain. A. W. Dox

Physiochemical studies of the pathology of blood serum. II. I. M. Goldberg. Univ. Baku. *Z. ges. exptl. Med.* **55,** 413–24(1927).—The zones of pptn. for serum were studied with lactic acid buffers (cf. *C. A.* **22,** 4163). The addn. of agar, talc, peptone and gum arabic to the serum increased the zone of pptn. Gum arabic injected into rabbits increased the zone of pptn. of the serum. Bubbling CO_2 through the serum increased the zone of pptn., while bubbling air diminished the zone. G. suggests that the broadening of the zone of pptn. of globulins seen so often in pathologic conditions is due to acidosis. F. L. Dunn

Biochemistry of hemolysis with a description of the acetone method of separating analytically the components of the serum and the localization of antibodies in immune area. M. Piettre and A. Chrétien. *Collection of Works on Comparative Pathology* **1927,** 76; *Rev. hyg. med. prev.* **50,** 712(1928); cf. *C. A.* **22,** 3453.—A review of the literature stressing the importance of the proteins in this study was made. Exptl. data indicate only progress in the soln. of the complex problem here outlined. C. R. Fellers

Agglutination and colloidal reactions. F. W. Mulsow. *Proc. Iowa Acad. Sci.* **34,** 85 (1927).—A preliminary report of results which suggest that the agglutination reaction is dependent upon changes in surface tension and other colloidal properties. Alkalies have a stronger inhibiting action than acids. NH_4OH has very little effect as compared to NaOH or KOH. The weak acids, however, have as strong an inhibiting action as the stronger acids. Lactic and butyric acids inhibit in high dilns. Certain colloidal solns. have distinct inhibiting action such as soap soln., 5% acacia soln. and dil. solns. of agar. Egg albumin makes the reaction slower but does not prevent agglutination. Other substances which inhibit the agglutination reaction by their presence are saponin, bile and bile salts as Na taurocholate and Na glycocholate. W. G. Gaessler

Plasma chlorides in acute intestinal intoxication of children. G. L. Boyd. *Am. J. Diseases Children* **31,** 514–9(1926); *Physiol. Abstracts* **11,** 421.—Hypochloremia has been shown to be assocd. with severe fluid loss and with circulation of toxins of split protein nature. In 66 cases of acute intestinal intoxication with both factors

present hypochloremia was found in less than half. No relation was found between the degree of toxemia and the chloride concn. H. G.

The metabolism of salts in nephritis. G. L. Boyd, A. M. Courtney and I. F. Maclachlan. *Am. J. Diseases Children* **32**, 29–39(1926); *Physiol. Abstracts* **11**, 484.—The children were kept on a whole-milk diet, and the blood and excreta analyzed. Blood phosphates were usually increased and blood Ca was decreased in nephritis: the Ca balance was independent of blood Ca content, and was usually pos. High-blood phosphate usually accompanied acidosis, but the phosphate balance depended on the presence or absence of edema. The relation between Ca and phosphate is discussed. H. G.

Metabolism of salts in nephritis. II. Potassium, magnesium and sulfates. G. L. Boyd and A. M. Courtney. *Am. J. Diseases Children* **32**, 192–9(1926); *Physiol. Abstracts* **11**, 484.—Plasma K remains normal whatever the type of nephritis, and the kidney excretes the salts normally. Plasma Mg is always low, but the neg. balance due to excessive loss of the salts from the body is modified by the presence of edema. Usually there is evidence of sulfate retention, but this is not due to defective urinary excretion. H. G.

Metabolism of salts in nephritis. III. Chlorides and sodium. G. L. Boyd, A. M. Courtney and I. F. Maclachlan. *Am. J. Diseases Children* **34**, 218–33(1927); *Physiol. Abstracts* **13**, 98; cf. preceding abstr.—Chlorides and Na were detd. in the food, feces, urine and plasma in various types of nephritis. It was found that no consistent relationship exists between the ability of the kidney to conc. urinary chlorides and its response to other functional tests. Except in chronic azotemic nephritis, the plasma chlorides and the plasma Na are usually high. Edema and vomiting affect the values. H. G.

Action of hydrolyzed and autolyzed organs and tumors of mammals and fowls. A. H. Roffo and L. Garcia Velloso. *Bol. inst. med. exptl.* **3**, 553–61(1927); *Physiol. Abstracts* **13**, 122.—Although fresh exts. of tissues and tumors cause a fall in blood pressure with death, hydrolyzates and autolyzates are said to have no effect. H. G.

The diagnostic value of the sugar content in the cerebrospinal fluid. A. S. Giordano. *J. Lab. Clin. Med.* **12**, 858–64(1927); *Physiol. Abstracts* **12**, 566.—Estns. made by the Folin-Wu method show that the sugar normally ranges between 60 and 90 mg. per 100 cc. of fluid. The sugar content offers no differentiation between poliomyelitis, encephalitis, brain tumor and other non-bacterial affections of the central-nervous system, but in meningitis it is always lowered. The differential diagnosis of tuberculous and purulent meningitis is discussed. H. G.

Muscular exercise and insulin requirement in diabetes. A. Gerl and A. Hofmann. *Klin. Wochschr.* **7**, 59–63(1928); *Physiol. Abstracts* **13**, 100.—The blood sugar was detd. periodically throughout the day in 5 cases of diabetes receiving insulin. On days when muscular exercise was carried out the blood-sugar level was not higher in general, than when no exercise was taken. In some instances it was definitely lower. Conclusion: Muscular exercise tends to lower the insulin requirement and is therefore useful. The reasons for the favorable influence of exercise are discussed. H. G.

The relationship between the severe blood poisons and the catabolites of protein. The mechanism that causes pernicious anemia. F. Rosenthal, L. Wislicki and L. Kollek. Med. Univ. Klinic, Breslau. *Klin. Wochschr* **7**, 972–7(1928).—The blood picture that is obtained after chronic poisoning with NH_2OH and $BzNHNH_2$ is almost identical with that observed in pernicious anemia. The hydroxylamine group appears to be the agent that is responsible for the production of abnormal blood cells. Certain amines have long been considered to be blood poisons; but the real toxic agent is the hydroxylamine deriv. that is formed from the amine in the liver. Pernicious anemia may be caused by such oximes produced, in the liver, from protein cleavage products. All hydroxylamines are not blood poisons. Thus MeNHOH-COOH, iso-AmNHOHCOOH and MeNHOH are not blood poisons. $PhCH_2CH$-(NHOH)COOH does not, regularly, produce blood changes; but PhCH(NHOH)-CH_2COOH is a powerful blood poison. Of considerable physiol. significance is the fact that $PhCH_2NHOH$ and especially $NH_2CONHOH$ are severe blood poisons. The latter could, under abnormal metabolic conditions, quite possibly be produced from urea. Milton Hanke

Toxic action of diastase and cell injury. Kurt Boshamer. *Klin. Wochschr.* **7**, 978–80(1928).—Necrosis of the pancreas leads to the appearance of trypsin and amylase in the blood. Amylase is not toxic to normal tissue; but leads to an increased destruction of injured tissue. Milton Hanke

The bactericidines of the intestinal juice. Kurt Meyer and Walter Löwen-

BERG. Rudolf Virchow Hospital. *Klin. Wochschr.* **7,** 984–7(1928).—Duodenal juice is bactericidal. The bactericidal substance is thermostable to an unusual degree. Some samples of intestinal juice retain their bactericidal properties to a large extent even after boiling for 30 min. The ash is inactive. The juice retains its activity when it is passed through a Berkefeld filter or when it is dried *in vacuo.* The bactericidal substance is not inorganic, it is not a protein, it may be a colloid, but, if so, the degree of dispersion is high, and it is not a lipoid. The bactericidal action of intestinal juice varies considerably; but this property cannot be correlated with the enzyme content of the juice. MILTON HANKE

Tissue respiration in cases with metabolic disturbances or with diseases of the organs of internal secretion. ERNST LUCAS. Urban Hosp., Berlin. *Klin. Wochschr.* **7,** 991(1928).—The spectroscopic method of Meyer and Rheinhold was employed (cf. *C. A.* **21,** 123). Observations were made on the web tissue between the thumb and index finger. Hemoglobin is normally reduced in 2 to 3 minutes in the clamped web. In Basedow's disease the time of reduction is decreased to from 50 to 90 secs. In myxedema the time may be increased to 5 min. Obesity is associated with a long reduction time (about 3 to 3.5 min.). This method is simple, is not time-consuming, and is just as reliable an index of the basal metabolic rate as the respiration methods. MILTON HANKE

Allergy, anaphylaxis and idiosyncrasy in dermatology. BRUNO BLOCH. *Klin. Wochschr.* **7,** 1065–70(1928).—A review. MILTON HANKE

New carcinoma reactions and their clinical usefulness. KURT ATZERODT. *Klin. Wochschr.* **7,** 1076–8(1928).—A careful study of the albumin reaction of Surányi and of the dye reactions of A. Gross. None of these reactions gives reliable clinical information as to the presence of carcinoma. MILTON HANKE

The nature of allergens. II. Pollen of Dactylis glomerata. L. FARMER LOEB. Med. Clinic, Charité, Berlin. *Klin. Wochschr.* **7,** 1078–9(1928); cf. *C. A.* **22,** 3692.—An aq. ext. of *Dactylis glomerata* gives a pos. skin reaction with certain hay fever patients. Addn. of alc. to this aq. ext. produces a ppt. which is active. The alc. filtrate in inactive. Tryptic digestion of the alc. ppt. destroys the active substance. The allergene of *Dactylis glomerata* is a protein. MILTON HANKE

Experimental sensitization and allergic reactions of the skin toward myoarsphenamine. E. NATHAN AND ANTON MUNK. *Klin. Wochschr.* **7,** 1125–8(1928).—Myoarsphenamine in 1% soln., can be injected intradermally without irritation. A local reaction is obtained in patients that are sensitive to arsphenamine. A generalized sensitization of the skin occurs in some patients so that the site of primary injection flares up upon reinjection of a new area 8–10 days later. In 2 cases the skin sensitization was so severe that a generalized urticarial exanthema was produced. MILTON HANKE

Glycogen, glucose and lactic acid content of benign and malignant tumors. FR. BERNHARD. *Klin. Wochschr.* **7,** 1184–5(1928).—The glucose concn. in benign and in malignant tumors is identical. Malignant tumors contain 10 times as much glycogen as do the benign tumors. The lactic acid content of malignant tumors is higher than that of benign tumors. Lactic acid determinations in the blood are of no value for the diagnosis of carcinoma. MILTON HANKE

The pathophysiology of fat metabolism after splenectomy. SAMUEL LEITES. Med. Inst. of Charkow. *Klin. Wochschr.* **7,** 1186(1928).—The ingestion of 100 g. oleic acid (dog) after splenectomy leads to an elevation in the β-hydroxybutyric acid and acetoacetic acid content of the blood from the right heart and the femoral vein and artery. The ingestion of olive oil or of olive oil plus cholesterol, after splenectomy, does not usually lead to an elevation of the ketone body concn. in the blood from the right heart; but does lead to an increase in the "acetone bodies" in the blood from the femoral vein and artery. MILTON HANKE

The relationship between the parotid, pancreas, blood sugar and diabetes mellitus. S. SEELIG. Charite, Berlin. *Klin. Wochschr.* **7,** 1228–30(1928).—Ligation of the ducts of the parotid gland leads to a reduction in the blood-sugar concn. The hyperglucemia produced in dogs by pancreatectomy cannot, however, be greatly modified by ligating the parotid ducts unless the ligation is carried out some time before pancreatectomy. Of 10 cases of human diabetes in which the parotid glands were ligated, 7 showed signs of improvement and three did not. MILTON HANKE

The serological diagnosis of syphilis by flocculation of cholesterolized extracts. (Citochol reaction and lentochol reaction). H. SACHS AND E. WITEBSKY. *Klin. Wochschr.* **7,** 1233–4(1928).—The modification consists in using a more concd. (3 times) alc. ext. of beef heart that is then properly cholesterolized. The reaction is rapid; hence it is

referred to as the citochol reaction as against the slower process, using non-concd. beef heart exts., which is called the lentochol reaction. M. H.

Action of liver diet on the erythrocyte and the cholesterol content of blood. WILH. BECK. *Klin. Wochschr.* **7,** 1235–6(1928).—Severe, secondary, post-hemorrhagic anemias, the anemia associated with malignant tumors, anemia of aleukia hemorrhagica, constitutional anemia of twins, anemia of hypothyreosis are not beneficially influenced by a liver diet or by liver exts. Mild secondary anemias (tuberculosis, endocarditis), alimentary anemia of children, anemia of scurvy or rickets and pernicious anemia are benefitted by the liver diet. The erythrocyte count of normal individuals can be raised from 4.5 to 6.7 million. The cholesterol content of the blood is elevated to above normal in all cases that are benefitted by the liver diet. The resistance of the erythrocytes is increased as the cholesterol content increases. MILTON HANKE

Measurement of the oxygen tension of the urine and its significance for the pathology of the circulation and the kidney. FRITZ MAINZER. Hospital, Altona a. Elbe. *Klin. Wochschr.* **7,** 1277(1928).—The concn. of O in the urine must bear a direct relationship to the O tension of some place in the body, probably the kidney. It should, therefore, undergo a change in certain diseased conditions. In 4 cases of severe decompensated vascular disease the O tension of the urine was found to be markedly subnormal. MILTON HANKE

Variations in the potassium and calcium content of serum in dermatitis. E. NATHAN AND FR. STERN. *Klin. Wochschr.* **7,** 1375–6(1928).—A brief report. The detailed report is to appear in the *Arch. Dermatol. u. Syphilis* **1928.** M. H.

Metabolism in pernicious anemia particularly after treatment with liver. K GRASSHEIM. Charité, Berlin. *Klin. Wochschr.* **7,** 1424–5(1928).—Pernicious anemia is associated with an increased basal metabolic rate. The O consumption usually becomes normal as the blood becomes normal on a liver diet. There are cases, however, in which the liver treatment leads to a normal blood picture; but the O consumption remains high. MILTON HANKE

Changes in the concentration of potassium, calcium and choline in the blood during an attack of angina pectoris. D. DANIELOPOLU AND MARIA MAXIM. *Klin. Wochschr.* **7,** 1466–7(1928).—Blood K and choline are markedly increased (Ca normal) during an attack of angina pectoris. The K and choline concns. regain their normal values 0.5 hr. after the attack has subsided; Ca is increased above normal. These results are identical with those obtained by stimulation of the sinus caroticus in animals. MILTON HANKE

Cholesterol metabolism. H. BEUMER AND F. HEPNER. *Klin. Wochschr.* **7,** 1470(1928).—Cholesterol that is injected intravenously is not excreted by the liver into the gall bladder. It appears to be excreted into the intestinal tract. Bacteria can synthesize cholesterol. A portion of the cholesterol that is found in feces must, therefore, be of bacterial origin. MILTON HANKE

The treatment of diabetes with a low fat diet. III. High carbohydrate diets in the treatment of emaciated diabetics. D. ADLERSBERG AND OTTO PORGES. *Klin. Wochschr.* **7,** 1503–7(1928).—A high carbohydrate, low fat diet, given in conjunction with insulin leads to a rapid tissue reconstruction in emaciated diets. The blood sugar may be increased; but a compensatory rise in the kidney threshold occurs which prevents excessive glucosuria. MILTON HANKE

Fever, thyroid and adrenals. Experiments on cats. W. BORCHARDT. *Klin. Wochschr.* **7,** 1507–9(1928).—The chem. fever induced by tetrahydronaphthylamine and the infection fever produced by pneumococci are not reduced materially by removal of the thyroid and parathyroid glands. The same is true when the adrenals are removed. Fever cannot be produced in normal cats (but can be produced in pregnant animals) that have had the thyroid, parathyroid and adrenals removed. Animals that have been treated with thyroxine or with ephetonin become somewhat feverish when the 3 above-mentioned glands are removed. Decapitated or decerebrated animals do not become feverish. MILTON HANKE

The stomach as a regulator of the acid-base balance. MICHAEL BAKALTSCHUK. *Klin. Wochschr.* **7,** 1551–3(1928).—Inhalation of air to which 3 to 5% of CO_2 has been added leads to a condition of general acidosis and a compensatory secretion of HCl by the gastric mucosa. The stomach is called upon, in this manner, to assist in controlling the acid-base balance in the body when other mechanisms have failed. M. H.

Significance of the non-fermentable reducing substances of the blood in diabetes. ISRAEL M. RABINOWITCH. Montreal General Hospital. *Biochem. J.* **22,** 753–7(1928).—The metabolism of non-fermentable substances is not disturbed in diabetes (cf. Folin, *C. A.* **21,** 122). BENJAMIN HARROW

Amino acids of flesh. II. Comparison of the diamino-acid content of some normal and pathological tissues. JOHN LEWIS ROSEDALE. St. Thomas' Hospital Med. School, London. *Biochem. J.* **22,** 826–9(1928).—No essential differences are obtained in using either Kossel or Van Slyke's method for detg. the diamino-acid method of animal tissues. Low content of lysine has been found in carcinoma, and in chickens which have derived the whole of their food-protein from maize. B. H.

Further studies of the relation of Bacillus acidophilus to dental caries. III. RUSSELL W. BUNTING, MARY CROWLEY, DOROTHY G. HARD AND MARGARET KELLER. Univ. Michigan. *Dental Cosmos* **70,** 1002–9(1928).—The growth of *Bacillus acidophilus* and the occurrence of dental caries are markedly reduced by a well-balanced diet practically free from sugar and candy, use of hexylresorcinol as a mouth wash, and topical application of metaphen after oral prophylaxis. JOSEPH S. HEPBURN

Calcium oxalate as a foreign constituent of salivary calculus. BERNARD B. BADANES. *Dental Cosmos* **70,** 1018–9(1928).—Ca oxalate may occur in salivary calculus. It is formed by a reaction between sol. oxalates in the food and Ca salts of the saliva. JOSEPH S. HEPBURN

Mottled enamel: report of an examination of an afflicted district in Italy. FREDERICK S. MCKAY. *J. Dental Research* **8,** 353–65(1928); cf. *C. A.* **21,** 2707.—Conclusive evidence was obtained that the water used during the years of growth of the enamel of the teeth is the one etiological factor in the occurrence of mottled enamel. JOSEPH S. HEPBURN

Anaerobic-delayed heat production after a tetanus. W. HARTREE AND A. V. HILL. Univs. Cambridge and London. *Proc. Roy. Soc.* (London) **B103,** 207–17(1928).—The anaerobic-delayed heat production after a tetanus may be due to phosphate changes or, more probably, to overstimulation of some of the muscle fibers and the resulting delayed formation of lactic acid. A muscle may give an excellent response to stimulation after hours in an atm. of N_2 contg. HCN. JOSEPH S. HEPBURN

The attraction of lymphocytes by homeotoxins. R. J. CROSSEN. *Arch. Path.* **6,** 396–403(1928).—If one carries out in the same animal an autotransplantation of cartilage and one of lymph gland, and places both transplanted tissues in close proximity to each other, the lymphocytes of the lymph node remain inactive, because the individuality differentials are identical in both tissues and the autosubstances do not exert a stimulating action on the lymphocytes. If by the same method one combines an autotransplanted lymph node and a piece of homeotransplanted cartilage, one may, under favorable conditions of experimentation, observe a definite migration of the lymphocytes from the lymph gland toward and into the transplant; in this case the individuality differential of the cartilage differs from that of the lymph node, and, as a result of this difference, homeotoxins develop which attract the cells from the lymph node in the direction of the cartilage. In the accumulation of lymphocytes around a homeotransplant, one has, in all probability, to deal with a chemotropic reaction. HARRIET F. HOLMES

The microscopic changes of heterophile skin reactions. The pathology of heterophile skin reactions. W. W. REDFERN. *Arch. Path.* **6,** 585–94(1928).—A microscopic study was made of the reaction produced by the injection of heterophile antiserum into the skin of the normal guinea pig. The early changes observed were capillary hemorrhage and extensive thrombosis of the minute vessels. Beginning necrotic degeneration of connective tissue elements was also evident. When coagulation of the blood was prevented by the use of heparin, the reactions developed as usual and ecchymosis was still pronounced. This indicated acute early injury to capillary endothelial cells. It is evident that injury and death of the cell take place rapidly after the antigenic and antibody factors have combined. That neither factor is, of itself, toxic has been shown that a new substance which is toxic results from the reaction between antigen and its specific antibody seems possible, but this has not been clearly proved. Thus far R. has been unable to produce a toxic substance by the combination of heterophile antigen and antibody *in vitro.* While the injection of normal serum led to a strong leucocytic response, immune serum showed an apparent lack of chemotactic power. HARRIET F. HOLMES

Heterophile antigen in human blood. I. DAVIDSOHN. *Arch. Path.* **6,** 632–7 (1928).—The results confirm the opinion of previous writers that the heterophile antigen present in human blood, type A, has common receptors with the Forssman antigen in sheep blood, but is not identical with it. HARRIET F. HOLMES

The influence of dietetic factors on the intensity of symptoms produced during acute experimental nephritis. S. J. COWELL. *Brit. J. Exptl. Path.* **9,** 164–70(1928).—A diet composed entirely of cabbage affords considerable protection from the severe toxic

effects that may be produced by small doses of U nitrate in rabbits fed on an ordinary lab. diet of oats, bran and a small allowance of green food. It is suggested that this protective effect of the cabbage diet is not due to its low protein content, nor to its capacity for producing an alk. urine. Attempts have been made to sep. from whole cabbage some fraction which contains a protective factor, and though the evidence is not completely conclusive, such a factor appears to be present in a watery ext., and may possibly exist in a dialyzed watery ext. HARRIET F. HOLMES

The action of vibrion septique and B. welchii toxin on isolated organs. G. A. H. BUTTLE AND J. W. TREVAN. *Brit. J. Exptl. Path.* **9**, 182–98(1928).—Small doses of septique and Welch toxin cause a spasmodic contraction of rabbits' uterus *in vitro* and a diminution of the size of spontaneous contractions, and the normal contraction to adrenaline is diminished. The toxin of v. septique is destroyed by bubbling air, O or H through the Ringer soln. The action of the *B. septique* toxin is reversible as the normal condition is restored by washing with Ringer's soln. and by adding a large amt. of serum. The concn. of toxin producing effects on smooth muscle in aerated Ringer's soln. is of the same order as that in the blood of a rabbit receiving an av. lethal dose. A small dose of v. septique toxin added to a bath of oxygenated Ringer's soln. contg. a piece of uterus renders the tissue insensitive to the action of larger doses of either v. septique or *B. welchii* toxin. The important part of the action of the 2 toxins is specific in that they are neutralized by the appropriate antisera and not by other antisera. There is a trace of non-specific toxic material in both toxins. By using this effect titrations of antitoxin potency of sera have been carried out. Uteri from rabbits immunized against v. septique toxin reacted to the toxin in the same way as normal uteri. HARRIET F. HOLMES

The preparation of antigenic specific substance from Staphylococcus pyogenes aureus. H. B. DAY. *Brit. J. Exptl. Path.* **9**, 198–206(1928).—The specific substance from staphylococci is liberated in an active antigenic state. Complete loss of activity follows unless the free specific antigen is protected from the action of living cocci and their enzymes. This destructive effect is not immediate, so that it is possible to obtain active specific substance from staphylococci undergoing rapid autolysis by methods which ensure prompt sterilization and cessation of further enzyme cleavage. The best results are obtained by extg. staphylococci at a temp. which destroys enzymes. HARRIET F. HOLMES

Diabetes. A statistical study of 2000 cases. HENRY J. JOHN. Cleveland Clinic. *Arch. Internal Med.* **42**, 217–47(1928); cf. *C. A.* **21**, 1845.—"In this series 46.75% cases were in males and 53.25% in females. The relative age incidence from the highest to the lowest according to age decades was: 6, 7, 5, 4, 3, 2, 1. There was a hereditary history of diabetes in 5.3% and a familial history in 4.5%. The highest blood sugar level on admission was 0.908%. Glucosuria was found in many diabetic persons with normal blood sugar, but it was missing in many patients with high blood sugar (highest blood sugar without glucosuria 0.390%). The general belief among the laity that *insulin* once used must always be used is shown to be fallacious. The blood sugar response to insulin varies tremendously. It also varies from day to day in the same case. Insulin reactions are not wholly due to hypoglucemia, but are found fairly frequently in the presence of hyperglucemia (a case with 0.467% glucose). Many normal persons have a blood sugar content as low as 0.03–0.04%. The total no. of patients with diabetic coma in this series was 4.25%. Of the 59 patients treated 11 died. In these cases the blood sugar on admission was 0.2–1.664%, the plasma CO_2 9.9–44.3, the highest figures appearing in patients who had received insulin before they were admitted. The total mortality was 6.55%. The incidence of syphilis was 2.7%." MARY JACOBSEN

The bacteriology of rheumatic fever and the allergic hypothesis. HANS ZINSSER AND H. YU. Harvard University Medical School. *Arch. Internal Med.* **42**, 301–9 (1928).—A report of 4 cases which present evidence in favor of the allergic hypothesis. MARY JACOBSEN

Blood destruction in chronic malaria and other splenomegalies. P. B. VAN STEENIS. *Geneeskund. Tijdschr. Nederland. Indië* **68**, 401–25(1928).—In normal natives (Java?) the feces urobilin (I) is 80 mg., the urine urobilin (II) > 0.4 mg./24 hrs.; serum bilirubin > 0.4 (Hymans v. d. Bergh). Erythrocyte resistance: beginning hemolysis at 0.44–0.50% NaCl, complete hemolysis at 0.32–0.38% NaCl. Vital staining of erythrocytes (Widal-Chauffard) is 1–19%. During the acute malaria attack I increases 20 times, II even more. They fall rapidly with the disappearance of fever and parasites from the blood. In chronic malaria with splenomegaly I is increased about 2.5 times, as a result of splenomegaly even in the absence of fever. II

may often be normal. During a relapse I and II are slightly higher than the av. values in chronic malaria. The blood destruction as a result of a relapse is as a rule insignificant when compared with the const. marked destruction assocd. with splenomegaly. The anemia in chronic malaria is therefore essentially a splenic anemia. In hyperplastic splenomegalies of other origin (syphilis, chronic septicemia with or without malaria) the anemia is of the same nature and goes over into hemolytic icterus. I and II are not increased in non-hyperplastic splenomegalies (idiopathic eosinophilia-polyglobulia). I and II are the most exact measure of blood destruction and regeneration, better than the usual morphological blood detns. The vital stain detns. agree well with I and II and may replace it provided the hemoglobin content remains const.
MARY JACOBSEN

Glucemia in tuberculosis of childhood. A. BARATTA. *Pediatria Rivista* **36**, 807–11 (1928).—In a group of 42 children 2–16 years old the blood sugar was about normal (0.99%) in the initial stages provided the state of nutrition was good. It was 0.74% in pulmonary tuberculosis and 0.77% in scrofula. MARY JACOBSEN

Alkaline reserve in bone and joint tuberculosis especially in relation to ultraviolet treatment. GIUSEPPE JEMMA. *Pediatria Rivista* **36**, 878–82(1928).—In 20 patients 3–14 years old the alk. reserve was lowered (av. 48.2), especially in pronounced toxic conditions. Irradiation with ultra-violet light improved the general conditions and restored the normal alk. reserve. MARY JACOBSEN

Albuminuria of childhood. A. MAZZEO. *Pediatria Rivista* **36**, 894–8(1928).—Review. MARY JACOBSEN

Some recent tests of liver function. J. ROUILLARD. *Rev. méd.* **45**, 5–31(1928).—Review. MARY JACOBSEN

The importance of the adrenal cortex for the pathogenesis of experimental scurvy. ELISA MORELLI AND V. M. GRONCHI. *Rev. sud-americana endocrinol. inmunol. quimioterap.* **11**, 437–55(1928)(In Italian).—In exptl. scurvy of guinea pigs and rabbits the adrenal secretion is markedly impaired. The lipoid material disappears almost entirely while the fuchsinophilic granules and siderophilic cells show a considerable increase in no. The acetone exts. which normally contain only traces of a *hemorrhage-producing substance* show a great increase in this poison, which in its action resembles lysocythin. A tendency to capillary hemorrhages in the adrenals has been observed in all diseases in which the latter are directly or indirectly affected: infectious diseases or poisoning with war gas, vesicants, some As compds. and a no. of other poisons. M. believes that with the onset of adrenal dysfunction the normally inhibited production of the capillary poison is unleashed. MARY JACOBSEN

Dietetic and allergic factors in infantile eczema. LEON H. DEMBO. *Am. Med.* **34**, 357–60(1928). FRANCES KRASNOW

Practical experiences with malaria prophylaxis in Monrovia (Liberia). W. O. WEHRLE. *Arch. Schiff-Tropen Hyg.* 32, 194–7(1928).—Discussion. F. K.

Neutral red test for gastric function. ST. KARTAL. *Arch. Verdauungs-Krankh.* **42**, 189–97(1928).—After an Ehrmann test meal, the HCl secretion is detd. at $^1/_4$-hr. and $^1/_2$-hr. intervals for $3^1/_2$ hrs. Then 5 cc. of a 1% soln. of neutral red is injected intramuscularly and the gastric secretion tested in the same way. In about 70% of the cases neutral red secretion parallels the HCl secretion. F. K.

Neutral red test for gastric function. K. GLASSNER AND H. WITTGENSTEIN. *Arch. Verdauungs-Krankh.* **42**, 698–9(1928).—Discussion of Kartal's paper. *Cf.* preceding abstract. FRANCES KRASNOW

Serological reactions of lipoids in the organism. H. SACHS. Inst. für exptl. Krebsforschung in Heidelberg. *Arch. Verdauungs-Krankh.* **42**, 353–61(1928). F. K.

Leanness and insulin. Hyperinsulinism. FERNANDO DA FONSECA. *Arch. Verdauungs-Krankh.* 42, 363–77(1928).—Insulin seems to det. the appearance of the fat-depot either by facilitating transformation of carbohydrate or by influencing the sugar oxidation. FRANCES KRASNOW

Insulin and gastric function. J. H. CASCAO DE ANCIÃES. *Arch. Verdauungs-Krankh.* **42**, 377–82(1928); cf. *C. A.* **22**, 270.—Insulin may be used for the differential diagnosis of function, org. achlorhydria and hypochlorhydria as well as for the treatment of gastric neurosis. FRANCES KRASNOW

The clinical significance of titration and hydrogen-ion determination in fractions of gastric contents. O. WINTERSTEIN. Chirurg. Univ.-Klinik Zurich. *Arch. Verdauungs-Krankh.* 42, 579–604(1928). FRANCES KRASNOW

Gastric diseases during the last 30 years (1897–1927). A critical study. L. KUTTNER. Rudolph Virchow-Krankenhauses zu Berlin. *Arch. Verdauungs-Krankh.* **43**, 1–37(1928). FRANCES KRASNOW

Correlation between the constitution of the organism and the chemical content of gall stones. M. T. Liefschitz. Ukrainer Röntgenologischen und Radiologischen Staats-Instituts zu Charkow. *Arch. Verdauungs-Krankh.* 43, 299–314(1928).—No conclusive results as to correlation are given because there are too few cases. In cholesterol-Ca bilirubinate gall stones, 98% is cholesterol. This occurred 3 times as often in the female as in the male cases studied. Frances Krasnow

Ptyalin observation on the healthy and sick. Eugen Solms. *Arch. Verdauungs-Krankh.* 43, 429–32(1928).—Diastase values vary greatly. Only 1 case of acute pernicious anemia showed a very low diastase content. Frances Krasnow

Some observations on Herxheimer's reaction. C. H. Hasselmann. *J. Philippine Islands Med. Assoc.* 8, 53–5(1928).—No reaction was obtained in 19 cases of untreated secondary syphilis when distd. water, aolan or triphal was administered. However, 10 of these 19 cases developed well marked reactions following arsphenamine treatment. Herxheimer's reaction is interpreted as an intermediate local reaction between the parasite and its metabolic products on the one hand, and the humeral and cellular allergy of the surrounding tissue on the other. Frances Krasnow

The carbon dioxide combining capacity of the plasma in lepra reaction, and the effects of the administration of sodium bicarbonate and other drugs. Elisa Roxas-Pineda, Catalino Nicolas and C. B. Lara. *J. Philippine Islands Med. Assoc.* 8, 207–16(1928).—In 18 cases of uncomplicated leprosy the readings varied from 61 to 69 vol. %. In 44 reaction cases the reading varied from 48 to 69 vol. %. Treatment with either $CaCl_2$ or $NaHCO_3$ or both gave good results. NH_4Cl aggravated the lepra reaction. Frances Krasnow

"Filterable viruses." A review. J. Jackson Clarke. *J. Trop. Med.* 31, 220–1 236–9(1928). Frances Krasnow

Studies in bacterial metabolism. LXXXV. The physiologic action of histamine applied directly to the mucosa of the isolated surviving intestine of the guinea pig. Arthur I. Kendall and Philip L. Varney. Washington Univ., St. Louis. *J. Infectious Diseases* 41, 143–55(1927).—By a specially devised app. the difference in the response of intestinal strips to histamine applied directly to the mucosa and the serosa is shown. In the former the response is slow but progressive, but when applied to the serosa contractions appear abruptly and are rapid. The response to applications to the mucosa can be obtained only with neutral or slightly alk. solns. of histamine, acid solns. being completely or nearly inactive. The intestines from young guinea pigs are in general more responsive than intestines from older animals. The response to applications to the mucosa indicates a slow but definite absorption of histamine from the lumen. Dil. CH_3OH prevents or relaxes contractions induced in isolated surviving intestinal strips, depending on whether it was applied before or after the introduction of histamine. **LXXXVI. Anaphylactic contraction induced through the mucosa of the isolated, surviving intestine of the guinea pig.** *Ibid* 156–63.—By using the technic of the preceding expts. anaphylactic contractions of surviving isolated intestinal strips from sensitized guinea pigs could be demonstrated after applying antigen directly to the mucosa. These contractions were similar to those produced by histamine. They were relaxed or prevented by dil. solns. of CH_3OH and were enhanced by dil. alkalies. Julian H. Lewis

Agglutinin response to certain Brucella abortus bacterins. S. J. Schilling and Wm. L. Bleecker. Agr. Expt. Sta., Fayetteville, Ark. *J. Infectious Diseases* 41, 222–32(1927). Julian H. Lewis

Preparation of Salmonella pullorum antigens for complement-fixation tests. L. D. Bushnell and C. B. Hudson. Kansas Agr. Expt. Sta., Manhattan. *J. Infectious Diseases* 41, 383–7(1927).—A satisfactory antigen for use in complement-fixation tests is made by extg. the centrifuged organisms twice with ether and suspending in salt soln. The turbidity of this prepn. makes it unadapted to some tests. An equally satisfactory antigen is obtained by centrifuging the organisms twice after thorough agitation, the last supernatant fluid being the antigen. Julian H. Lewis

Complement fixation and agglutination tests for Salmonella pullorum infection. L. D. Bushnell and C. B. Hudson. Kansas Agr. Expt. Sta., Manhattan. *J. Infectious Diseases* 41, 388–94(1927).—The antigenic substance obtained by washing *Salmonella pullorum* with salt soln. is thermostable and does not act freely in the presence of the cells. All organisms are not equally rich in it. The complement fixation and agglutination tests have about the same value in testing for carriers of *S. pullorum*. A combination of the 2 tests is more decisive, leaving a small no. of questionable cases. Julian H. Lewis

The reaction of the dog to the continuous intravenous injection of B. coli. Bac-

teriological and chemical studies of the lymph. WM. F. PETERSON, ERNST F. MÜLLER AND WM. BOIKAN. Univ. of Ill., Coll. of Med., Chicago. *J. Infectious Diseases* **41**, 405-6(1927).—With the continuous intravenous injection over a considerable length of time (6-24 hrs.) of a dil. suspension of *B. coli* into the dog it was possible to reproduce the clinical picture of the onset and course of an acute, severe, infectious process. By a chem. analysis of the thoracic lymph during such a procedure the changes within the animal could be interpreted, which consisted for the most part of a splanchnic stimulation. There are, however, to be recognized a latent period; the period of fluctuations, with cellular efforts of restoration of the equil.; the period of max. injury, and the premortal period. Only during the period of max. injury do bacteria pass from the blood stream to the lymph channels. JULIAN H. LEWIS

Action of hemotoxins on oxygenated and reduced blood. I. B. welchii toxin. GUILFORD B. REED, J. H. ORR AND W. A. CAMPBELL. Queen's Univ., Kingston. *J. Infectious Diseases* **41**, 434-8(1927).—The oxidation of *B. welchii* toxin by exposure of toxic filtrates to the air for 24 hrs. resulted in considerable loss of hemotoxic action. The hemolysis of oxygenated red cell suspensions requires a much higher concn. of *B. welchii* toxin than reduced red cell emulsions. This may result from an oxidation-reduction relationship between the toxin and hemoglobin or it may depend upon a difference in the absorption of toxin by oxygenated and reduced blood. J. H. L.

Is the antigenic action of hemoglobin due to globin? LUDVIG HEKTOEN AND KAMIL SCHULHOF. John McCormick Inst. for Infectious Diseases, Chicago. *J. Infectious Diseases* **41**, 476-8(1927).—An antihemoglobin serum had a titer high enough that it gave reactions with a purified globin soln. when dild. high enough to eliminate the reaction of the hemoglobin contained in the globin as an impurity. It is thought probable from this expt. that the antigenic properties of hemoglobin are due to the globin radical rather than to hemoglobin, although the possibility of a 3rd group is not yet excluded. JULIAN H. LEWIS

Tissue hydration and its relation to susceptibility and immunity. J. B. WHERRY. *J. Infectious Diseases* **41**, 177-89(1927).—The local edema produced in infection is deemed to be an adaptive reaction in which the substances required by the bacteria are brought in soln. At the same time opsonins are dild. It is suggested that this hydration of tissues is brought about by amines produced by an interaction between parasite and host. Such interaction occurs when heat-killed bacteria are injected intradermally into human beings. The response varies with the species of bacteria and with the individual. The production of local urticaria, or this followed by immediate congestion, is taken to indicate susceptibility; when the whole process is greatly aggravated the next day the reaction is taken to indicate sensitivity. Antigens so selected and given by the desensitization method yield excellent therapeutic results due to the production of opsonins and of a lessened tendency to tissue hydration. JULIAN H. LEWIS

The Kahn test in experimental syphilis. JOHN E. WALKER. Army Medical School, Washington, D. C. *J. Infectious Diseases* **41**, 233-7(1927).—Only 36% of normal rabbits gave negative reactions as compared with 99.8% in normal human beings. The reaction in rabbits became stronger after inoculation with syphilis usually in direct proportion to the severity of clinical symptoms. The increase in strength was more after intratesticular injection than after scrotal inoculation. With a decrease in size of the lesions the strength of the reaction decreases. The reaction can be made sp. for syphilis in rabbits by subtracting 40 quant. units from the results. JULIAN H. LEWIS

Action of B. welchii toxin and other hemotoxins on erythrocytes in vivo. GUILFORD B. REED, J. H. ORR AND C. MARION SPENCE. Queen's Univ., Kingston, Canada. *J. Infectious Diseases* **41**, 283-8(1927). **Action of B. welchii toxin and other hemotoxins on erythrocytes in vitro.** GUILFORD B. REED AND J. H. ORR. *Ibid* 289-93. JULIAN H. LEWIS

Nonspecific Wassermann and agglutinin reactions with serum from patients with febrile diseases. MARION CORRIGAN. Michael Reese Hospital and Nelson Morris Inst., Chicago. *J. Infectious Diseases* **41**, 457-60(1927).—Wassermann reactions, typhoid agglutination and *B. proteus* X agglutination were observed to occur with serums of patients with high temps., but on so few occasions that a casual relationship of the temp. may be doubted. The temp. on the other hand may be instigative of a latent luetic condition or of the fluctuation of nonsp. agglutinating antibodies. J. H. L.

The proteases and antiproteases of pleural exudates. CHARLES WEISS. College of Physicians and Surgeons, Columbia Univ., New York, and the School of Tropical Medicine, Univ. of Porto Rico, San Juan. *J. Infectious Diseases* **41**, 467-75(1927).—

Proteases and antiproteases are demonstrated and measured in the constituents of pleural exudates, with particular reference to their activity over a range of p_H concn.
JULIAN H. LEWIS

The proteins in egg white and their relationship to the blood proteins of the domestic fowl as determined by the precipitin reaction. LUDVIG HEKTOEN AND ARTHUR G. COLE. John McCormick Inst. for Infectious Diseases and Univ.. of Illinois. *J. Infectious Diseases* **42,** 1-24(1928).—Egg white contains 5 distinct antigens: ovoglobulin, ovomucin, crystallizable ovalbumin, non-crystallizable conalbumin and ovomucoid. Ovalbumin, ovomucin and ovomucoid may be completely freed from the other proteins present in egg white. The prepns. of ovoglobulin used were contaminated with ovomucin and probably with a slight amt. of ovalbumin. Antiserums against ovalbumin, ovoglobulin, ovomucin and ovomucoid give no reactions when tested with solns. of fibrinogen, euglobulin or albumin prepd. from the blood plasma of the fowl. An antiserum against the whole egg white reacts with the blood albumin and gives no reaction with the other blood proteins. It was shown, by fractionating the albumin in egg white, that this reaction is due to the presence in egg white of the non-crystallizable conalbumin. The conalbumin and the blood albumin are therefore immunologically, and probably chemically, identical. It was not possible completely to sep. conalbumin from ovalbumin and ovomucoid. Since, however, an immune serum against blood albumin contains a sp. precipitin for conalbumin, such a serum may be used to test for conalbumin in the various protein fractions of egg white.
JULIAN H. LEWIS

The specific precipitin reaction of the muscle hemoglobin of the dog. LUDVIG HEKTOEN, F. S ROBSCHEIT-ROBBINS AND G. H. WHIPPLE. John McCormick Inst. for Infectious Diseases, Chicago and the University of Rochester School of Medicine and Dentistry, N. Y. *J. Infectious Diseases* **42,** 31-4(1928); cf. *C. A.* **21,** 3674.—Muscle hemoglobin practically free from blood hemoglobin obtained from dogs gives a sp precipitin which differentiates it sharply from the hemoglobin of dog blood. Muscle hemoglobin introduced intravenously into dogs has about $^1/_5$ of the threshold of renal excretion which blood hemoglobin has and can be utilized only in small quantities to form red blood cells.
JULIAN H. LEWIS

Skin reactions with bacterial filtrates of anhemolytic streptococcus, hemolytic streptococcus and B. typhosus. KATHERINE M. HOWELL AND MARION CORRIGAN. Michael Reese Hospital and Nelson Morris Inst. for Medical Research, Chicago. *J. Infectious Diseases* **42,** 149-60(1928).
JULIAN H. LEWIS

Serum therapy of botulism in monkeys. GAIL M. DACK AND WILLARD L. WOOD. Univ. of Chicago. *J. Infectious Diseases* 42, 209-12(1928).—*Macacus rhesus* monkeys were found susceptible to the oral administration of small amts. of type A botulinus toxin. About 2000 m. l. d. (intraperitoneal) for mice was found lethal when fed to monkeys weighing approx. 2.5-4.0 kg. The administration of antitoxin after the appearance of symptoms of botulism failed to prevent death. Likewise no beneficial effects were shown when barbital was given simultaneously. The time of appearance of symptoms and death varied according to the amt. of toxin fed. Where small doses were given the time of appearance of symptoms was very much delayed and the symptoms persisted over a long time. Toxin was demonstrated in the blood of 6 out of 9 monkeys after the appearance of symptoms of botulism. No toxin was found in the blood of those monkeys which developed symptoms later than 24 hrs. after they were fed toxin. The results obtained by feeding botulism toxin to monkeys are similar to the results that have been reported for botulism in human beings.
J. H. L.

Serum reactions produced by feeding antigens. L. P. DOYLE. Univ. of Chicago and Agricultural Experiment Station, Purdue Univ., LaFayette, Ind. *J. Infectious Diseases* **42,** 218-25(1928).—Small quantities of antibody in the serum of rabbits fed with certain antigens can be detected better by the agglutinin than by precipitin or complement-fixation tests. In rabbits fed with living cultures of *B. aertrycke* and *B. enteritidis*, sp. agglutinins appeared promptly in the blood. When the cultures were killed in various ways and then fed to rabbits, agglutinins usually did not appear in the blood, although the killed cultures were shown to have agglutinogenic properties when injected subcutaneously. CHOH-killed cultures of *B. suipestifer* fed to young pigs produced well-defined symptoms of gastric irritation and gave rise to well-marked formation of agglutinin.
JULIAN H. LEWIS

Rapid macroscopic agglutination for the serum diagnosis of Bang's abortion disease. I. FOREST HUDDLESON AND ELIZABETH ABELL. Mich. State College, East Lansing. *J. Infectious Diseases* **42,** 242-7(1928).
JULIAN H. LEWIS

The protective substance in antipneumococcus serum. I. A separation of phos-

phorus and some inert protein from the water-insoluble precipitate of antipneumococcus serum. LLOYD D. FELTON. Harvard Medical School, Boston. *J. Infectious Diseases* **42,** 248–55(1928).—The antiserum is first pptd. with distd. H_2O. A soln. of this ppt. is re-pptd. with acid and a neutral salt to get rid of P-contg. inert protein, leaving behind a H_2O-insol. protein which contains the protective substance. While this is the principle of the method the details of its application for the best results remain undetd. JULIAN H. LEWIS

The protective substance in antipneumococcus serum. V. Febrile reaction from intravenous injection. LLOYD D. FELTON. Harvard Medical School, Boston. *J. Infectious Diseases* **42,** 256–62(1928).—The H_2O-insol. ppt. obtained by dilg. antipneumococcus serum with acidulated H_2O is pyrogenic, but when this fraction is freed from a protein contg. most of the P and lipins it no longer has this action on intravenous injection. JULIAN H. LEWIS

The spermatocyte reaction (testicular tuberculin reaction) in the albino rat. JOHN E. BLAIR. Hospital for Joint Diseases, New York. *J. Infectious Diseases* **42,** 435–9(1928).—The sp. allergic response of the testis to tuberculin described by Long (*Am. Review Tuberculosis* **9,** 215(1924)) was confirmed for guinea pigs but could not be obtained in the albino rat infected by intraperitoneal or intratesticular inoculation of human tubercle bacilli. JULIAN H. LEWIS

Search for protective, bacteriophagic and enzymic agents in pneumonic sputums. BERNICE E. EDDY. Univ. of Cincinnati. *J. Infectious Diseases* **42,** 449–60(1928).—There is protection, or a latent period in the time of death, of mice given injections with fatal doses of pneumococci mixed with filtrates of sputum from patients with lobar pneumonia after crisis, as compared with control mice receiving only broth with the dose of pneumococci. Protection or a latent period in the time of death of mice does not occur with filtrates of sputum obtained before crisis, with sputum filtrates from fatal cases, with sputum filtrates after crisis injected with pneumococci of different type from that infecting the patient, nor with the sputum filtrate boiled and injected with homologous pneumococci. A bacteriophage which might account for crisis was not recovered from the sputum. Proteolytic enzymes which would erode Loeffler's blood serum (Lord, *C. A* **13,** 3239; Lord and Nye, *C. A.* **15,** 3325) were demonstrated in the sputum of 2 pneumonia patients. JULIAN H. LEWIS

The nature of diphtheria toxin. ARTHUR LOCKE AND E. R. MAIN. St. Lukes' Hosp., Chicago. *J. Infectious Diseases* **43,** 41–59(1928).—A study of the conditions favoring growth and toxin production in differently prepd. cultures of a toxigenic strain of diphtheria bacillus indicated that toxin is not accumulated unless there is a definite growth momentum, a concomitant growth inhibition, and unless there are present enzyme-buffers like proteoses to protect the toxin from extracellular proteolysis. The toxin principle has been concd. and sepd. from the greater part of the accompanying precipitinogen and nonsp. principles, with acid as the precipitant. Prepns. were obtained with a N equiv. of 0.0006 ± 2 mg. per corrected Lf unit, which give intradermal skin reactions in dilus. approaching 1 part in a billion. These purified prepns. were unmistakably lipoprotein in character and contain no carbohydrate. They have an isoelectric range within that manifested by prepns. of the bacillary substance in which they have their origin and they are, like protoplasm, extremely sensitive to denaturation. The theory of the nature and origin of diphtheria toxin is discussed and the suggestion made that the antigenicity, antitoxin-binding power, and toxicity of bacterial toxins may be manifestations of an identical, more fundamental property—their combining avidity. JULIAN H LEWIS

Changes in blood dextrose in rabbits after intravenous injections of histamine. MAUD L. MENTEN AND HELEN M. KRUGH. Univ. of Pittsburgh. *J. Infectious Diseases* **43,** 117–20(1928).—The convulsions and shock produced by lethal doses of histamine in normal rabbits and rabbits immunized with *B. paratyphosus* and *B. enteritidis* may be accompanied by no appreciable change in the blood dextrose or by a maximal hyperglucemia The authors believe that these expts. indicate that allergy is not a factor in the production of agonal hyperglucemia. JULIAN H. LEWIS

Insulin content of the pancreas following intoxication of rabbits with paratyphoid B filtrate and dysentery bacilli. MAUD L. MENTEN AND HELEN M. KRUGH. Univ. of Pittsburgh. *J. Infectious Diseases* **43,** 121–5(1928).—Single intravenous sublethal injections of paratyphoid B filtrates do not appreciably alter the insulin content of the pancreas as demonstrated by comparative biological assays in test rabbits. The hypoglucemic potency of the insulin ext. of the pancreas from rabbits in which injections of *B. dysenteriae* (Shiga) had caused a prolonged fatal toxemia and hyperglucemia was slightly diminished. JULIAN H. LEWIS

The production of potent antipneumococcus serum in rabbits. B. L. FREEDLANDER. Univ. of California Medical School, San Francisco. *J. Infectious Diseases* **43,** 137–44(1928).—Rabbits were immunized with injections of exts. of infected rabbit tissue rendered sterile by centrifugation and addns. of rivanol. A type 1 antipneumococcus serum affords highest protection, type 2 serum to a lesser degree and type 3 serum gives no protection. By *in vitro* tests these sera show few agglutinins, no precipitins, no remarkable opsonic powers and no direct bactericidal action. Antipneumococcic serum from the rabbit is as effective as antipneumococcic serum from the horse in protecting mice against type 1 infection. JULIAN H. LEWIS

Incidence of cloudy reaction in agglutination tests for Salmonella pullorum infection. G. S. SCHILLING AND S. J. SCHILLING. Univ. of Arkansas, Fayetteville. *J. Infectious Diseases* **43,** 172–80(1928). JULIAN H. LEWIS

Certain constituents of acid-fast bacteria and their antigenic characteristics. I. Communication. A. KNORFF-PETERSON AND W. LIESE. Univ. Kiel. *Z. Immunitäts.* **51,** 87–114(1927).—By a study of the staining reactions of acid-fast bacteria after acid hydrolysis in aq. and alc. media and extn. with hot alc. it is shown that although tubercle bacilli have the same chem. structure as other acid-fast bacteria they are more stable. The Gram stain and acid fastness depend on different constituents, those responsible for the Gram stain probably being lipoproteins. Ext. of acid-fast bacteria with simple fat solvents, leaving the bacteria Gram-positive and acid fast, gives exts. which react as antigens in complement-fixation tests. They do not, however, react specifically with sera of tuberculosis patients. Exts. obtained with hot alc. after treating tubercle bacilli with acid, leaving the bacteria Gram negative and non-acid fast, do react specifically in tuberculosis. Such exts. from saphrophytic bacteria do not react in this way. JULIAN H. LEWIS

The biochemistry of antigens. F. PRZESMYCKI. Staatlichen Hyg. Inst., Warschau. *Z. Immunitats.* **51,** 408–20(1927).—From *Proteus* X_{19} *H* and typhoid bacteria a protein-free substance was isolated by the technic of Zinsser (*C. A.* **17,** 1072) which reacted strongly sp. with antibodies obtained by immunizing with whole bacteria Immunization with this substance together with hog serum produces no antibodies against itself. Bacterial lipoids with hog serum produce strong complement fixing antisera which react with lipoids from most bacteria and are therefore not species sp. Lipoids alone produce antibodies but in much lower titer. Immune sera produced by injecting whole bacteria react specifically with bacterial lipoids. It seems that bacteria in their entirety produce more sp. antibodies than their isolated constituents. JULIAN H. LEWIS

Skin injection and skin immunity in anthrax. TH. BAUTZ AND CH. AMIRASLANOV. Bacteriologischen Staatsinstitut, Baku. *Z. Immunitats.* **56,** 1–6(1928).—The findings of Besredka that cutaneous vaccination against anthrax is superior to subcutaneous vaccination are confirmed. However, contradictory to Besredka, there is no selective sensitivity of the skin to anthrax. On the other hand, the better results obtained with cutaneous vaccination are thought to be due to the ability to administer large enough amts. of organisms to produce antibodies yet without killing, which cannot be done by subcutaneous injections. JULIAN H. LEWIS

The speed of flocculation of antidiphtheria serum. K. CHALAPINA. Bakteriologischen Staatsinstitut, Baku. *Z. Immunitäts.* **56,** 7–10(1928).—Antidiphtheria sera, which differed from each other only in the speed with which flocculation occurred, when mixed with toxin, differed in their therapeutic action. The quicker flocculation occurred, the better the therapeutic results. These findings are different from those of Madsen and Schmidt (*Ann. inst. Pasteur* **40,** 300–2(1926)). JULIAN H. LEWIS

Formation of anatoxin. D. KISSIN AND L. BRONSTEIN. Staatlichen Centralen Bakteriol. Inst., Moskau. *Z. Immunitäts.* **56,** 11–23(1928).—On addn. of acid to toxin to a certain p_H a ppt. is formed which contains the toxic and flocculation properties of the original toxin. When the acid is added stepwise, 3 characteristic points are observed: (1) when the p_H reaches 6.2–6.3; (2) point of max. pptn.; (3) the appearance of free HCl. The relation of the 1st point to the 2nd is a const. 1:2 for fresh diphtheria toxin and 1:1 for its anatoxin, 1:1 for fresh tetanus toxin and 1:0.05 for its anatoxin. The change in the quotient when anatoxin is produced can be used as an indicator of the complete ripening of the anatoxin. A theory based on a hypothetical chem. formula for toxin is given to explain these effects of acid.

JULIAN H. LEWIS

Studies in anthrax infection. H. HRUŠKA. Staatlichen diagnost. und Serotherapeutischen vet. Inst., Ivanovice n. H. Tschechoslowakei. *Z. Immunitäts.* **56,** 49–59 (1928).—A formolized pulp of anthrax bacilli loses its ability to immunize guinea pigs

when given intracutaneously. Anthrax vaccine kept 2 yrs. in sealed ampoules lost its virulence and its ability to immunize guinea pigs even in very large doses. Formolized anthrax cultures and vaccines kept in sealed ampoules do not produce an active immunizing endotoxin. Formolized aggressins from the blood and spleen of a cow dead with anthrax vaccinated guinea pigs. This property of the aggressins decreased on diln. with NaCl. The aggressins are formol-stable and in the formolized state can be used a long time as a vaccine. Aggressins are reaction products of animals dead with anthrax. When injected subcutaneously into hyperimmune horses they produce a marked local edema. JULIAN H. LEWIS

Specific and subspecific antibodies. WL. MARKOFF. Inst. fur Baketeriologie und Serologie, Univ. Sofia. *Z. Immunitäts.* **56**, 95–106(1928).—Bacteriophage acting on bacteria progressively change their antigenic properties. Whole bacteria produce true antibodies while partially digested ones give rise to antibodies variously referred to as "subantibodies," "nebenantikörper," and "partial agglutinins." J. H. L.

Group specific antigens and antibodies. GREGOR GREENFIELD. Krankenhaus, Friedrichshain. *Z. Immunitäts.* **56**, 107–29(1928).—Several human sera were found which gave positive complement-fixation reactions sp. for group A. The reaction occurred not only with fresh red cells but also with alc. exts. The reactions with the alc. exts. were usually stronger. Specificity was proved not only with direct tests but also with absorption expts. Saliva gave strong group sp. tests. Group sp. flocculation tests were not obtained with the complement fixing sera and alc. exts. of red cells. Immunization of rabbits with group *A* red cells produced group and specie sp. antibodies. Beef serum absorbed with red cells of group *AB* was still active against group *O* red cells. The anti-O agglutinin in beef serum was usually stable for a long time although many sera lost their activity in a few days. The agglutinin was equally active at room temp. and at 0°. Anti-O agglutinin bound to red cells of group *O*, *A* or *B* can be readily recovered. Heart muscle cells of group *O* absorbed anti-O agglutinin stronger than did those of group *AB*. In 2 cases tried the heart muscle of group *A* absorbed anti-O agglutinins stronger than that from group *AB* and weaker than that from group *O*. JULIAN H. LEWIS

The heterologous antigens in human red cells and those of different animals. I. L. KRICHEVSKII AND R. E. MESSIK. Mikrobiol. Forschungsinstitut Volksbildungskommissariats R. S. F. S. R., Moskau. *Z. Immunitats.* **56**, 130–46(1928).—Forssman's antigen is found in red cells of all men independent of the 4 groups to which they may belong. In all 4 groups are also found, beside the Forssman antigen (sheep), the antigen of the hen, turtle, cat and hog. In the red blood cells of the sheep, hen, turtle and cat are found the heterologous antigen of man and the hog. J. H. L.

Specificity of the tuberculin reaction. M. MASTBAUM Bakteriologischen Institut der Universität, Kasan. *Z. Immunitats.* **56**, 147–54(1928).—Healthy guinea pigs sensitized with *B. coli* protein and with hog serum + old tuberculin reacted to tuberculin, but the histological nature and clinical course of these reactions were much different from those of the true tuberculin reaction. JULIAN H. LEWIS

Microbiotic specific precipitin and complement-fixation reactions. R. TORIKATA AND K. FUJIMORI. Univ. Kyoto. *Z. Immunitats.* **56**, 155–74(1928).—Removal of lipoid from antigen (cholera filtrates, native and heated) and anti-cholera serum did not affect the precipitin reaction but completely abolished the complement fixation reaction. Removal of lipoid from antiserum alone affected neither precipitin nor complement fixation reactions. Removal of lipin from antigen alone did not affect the precipitin reaction either quantitatively or qualitatively but did destroy the complement fixation reaction. An anti-cholera serum gave a good Wassermann reaction but did not after the lipoid was removed. In both precipitin and complement fixation reactions boiled antigen showed more avidity for antiserum than did the native form. JULIAN H. LEWIS

Impediment phenomena in complement-fixation reactions with cholera vibrios. K. FUJIMORI. Univ. Kyoto. *Z. Immunitäts.* **56**, 175–90(1928).—Boiled cholera antigens have a much greater avidity for complement-fixation antibodies than have native antigens. This difference can be measured accurately and expressed mathematically, and is thought to be due to the removal of certain thermolabile inhibitory substances. JULIAN H. LEWIS

The role of lipoids in immunization. Binding and detoxifying properties of lipoids. Lipoid vaccines. VITAL BRAZIL AND J. VELLARD. Staatlichen Serotherapeut. Inst. Butatan, Sao Paulo, Brazil. *Z. Immunitäts.* **56**, 191–209(1928).—Lipoids from normal serum and the liver have the common property of binding and detoxifying bacterial and snake venoms and of decreasing the virulence of bacteria. The similarity of these

lipoids indicates the importance of the liver as a protection against infection and intoxication in the production of lipoids. There are 2 stages in the action of lipoids on toxins, the first where there is a simple combination and fixation and second in which the toxin part is changed into a completely atoxic substance with its immunizing properties intact. Lipoids greatly reduce the virulence of anthrax bacilli. This property of lipoids introduces the possibility of the production of a new type of vaccine.

JULIAN H. LEWIS

The genesis and characteristics of bacterial toxins. M. EISLER. Staatlichen Serotherapeutischen Inst., Wien. *Z. Immunitäts.* **56,** 209-33(1928).—From the evidence obtained it is believed that bacterial toxins are not so much the products of bacterial metabolism as they are actual cell constituents coming from the bacteria as a result of an increased permeability of the cell membrane occurring at death or injury of the bacteria. JULIAN H. LEWIS

The antigenic action of milk. ERICH VON BAEYER. Inst. für exptl. Krebsforschung, Heidelberg. *Z. Immunitats.* **56,** 241-52(1928).—Antisera from rabbits immunized with boiled goat milk reacted stronger with boiled milk than with raw milk. This may be explained by the phenomenon of concurrence of antigens because in raw milk there are several antigens which mutually inhibit each other while in boiled milk the whey proteins are coagulated, leaving casein for the most part intact. On the other hand the difference between the 2 antisera may be only apparent. In titrating boiled milk and raw milk, equal vols. of the latter contain more protein than the former and a point in the series is reached where there is an excess of antigen which may inhibit complement fixation reactions whereas with boiled milk this same diln. may contain optimal concns. of antigen. Antisera against raw goat milk react with raw cow milk only and those against boiled goat's react with boiled cow milk. Anti-milk sera react with alc. exts. of milk. Antisera for boiled goat milk reacted stronger against alc. exts. of human liver, and guinea-pig kidney and liver than did antisera against raw goat milk. No reactions were obtained with either against alc. exts. of rabbit organs. These reactions and the presence of a strong hemolytic amboceptor for sheep red cells indicate the presence of Forssman's antigen in goat milk. JULIAN H. LEWIS

The action of auto-serum on blood vessel preparations. H. HASHIMOTO. Forschungsinstitut fur Hygiene und Immunitätslehre, Berlin-Dahlem. *Z. Immunitäts.* **56,** 253-8(1928).—The blood-vessel-contracting substance (auto-contractin) of normal serum from the same species as the prepn. of blood vessels is not destroyed by heating to 100° for 20 min. Auto-contractin, in contrast to hetero-contractin, has no relation to coagulation time of the blood. Auto-plasma, like hetero-plasma, is not toxic for blood vessels. JULIAN H. LEWIS

The action of homologous organ extracts on isolated blood vessels. H. HASHIMOTO. Forschungsinstitut für Hygiene und Immunitätslehre, Berlin-Dahlem. *Z. Immunitäts.* **56,** 258-65(1928).—Aq. exts. of guinea-pig organs, which are usually fatally toxic for guinea pigs, produce a marked vasoconstriction of guinea-pig blood vessels. In instances where this toxic action was weak a vasodilation was observed.

JULIAN H. LEWIS

The action of bacteria and red cells on the isolated blood vessels of animals sensitized with these substances. H. HASHIMOTO. Forschungsinst. für Hyg. und Immunitätslehre, Berlin-Dahlem. *Z. Immunitats.* **56,** 265-70(1928).—Blood vessel prepns. of rabbits and guinea pigs sensitized with bacteria and foreign red cells showed only a low-grade reaction to these substances. JULIAN H. LEWIS

The action of bacterial anaphylatoxins on the isolated blood vessels of guinea pigs and rats. H. HASHIMOTO. Forschungsinstitut für Hygiene und Immunitätslehre. *Z. Immunitäts.* **56,** 271-5(1928).—Anaphylatoxin prepd. by digesting bacteria with fresh guinea-pig serum produced a vasoconstriction in the isolated blood vessels of normal guinea pigs and, to a less extent, rats. JULIAN H. LEWIS

Lens anaphylaxis with isolated blood vessel preparations. H. HASHIMOTO. Forschungsinstitut für Hygiene und Immunitätslehre, Berlin-Dahlem. *Z. Immunitäts.* **56,** 276-8(1928).—The well-known organ specificity of the lens of the eye was demonstrated in guinea-pigs and rats, isolated blood vessel prepns. being used. J. H. L.

The inhibition of bacterial growth in human serum. L. K. WOLFF. Univ. Amsterdam. *Z. Immunitäts.* **56,** 279-87(1928). See *C. A.* **22,** 625. JULIAN H. LEWIS

The influence of cholesterol on experimental anaphylaxis. L. SURÁNYI AND L. JARNO. Pázmány-Péter Univ., Budapest. *Z. Immunitäts.* **56,** 303-7(1928). See *C. A.* **22,** 1190. JULIAN H. LEWIS

Chemical and serological experiments with various fractions of blood serum. R. KIMURA. Univ. Kyoto. *Z. Immunitäts.* **56,** 330-46(1928).—From the ether ext. of

beef erythrocytes 2 phosphatides were obtained and 1 from the alc. ext. The relation of P to N in the former was 1:2 and in the latter 1:2.5. Injected into rabbits these phosphatides produced no hemolysis for beef-red cells. By fractional pptn. with $(NH_4)_2SO_4$ 4 globulins and 1 albumin were obtained from beef serum. The S content of albumin was much higher than that of the globulins, and the easily salted out globulins contained more S than those salted out less easily. Lysin N is also higher in albumin than in the globulins. Monoamino acid N is higher in the less sol. globulins than in those more sol. There was no noticeable difference in the C, H_2O and total amide and humin N of the various protein fractions of serum. Between globulin and albumin there are marked serological differences and between 2 globulins most widely sepd. chemically. JULIAN H. LEWIS

Studies on the so-called antivirus of Bersedka. H. DOLD AND H. R. MÜLLER. Reichsgesundheitamts, Berlin. *Z. Immunitäts.* **56**, 347–74(1928).—Sterile filtrates from bouillon inoculated several times with bacteria, the so-called antivirus of Besredka, showed on renewed inoculation an inhibition of growth. Any effect of antivirus on infection, local or general, favorable or unfavorable, can be duplicated with plain bouillon or salt soln. If any reaction results it is due to a nonsp. local inflammatory reaction. JULIAN H. LEWIS

The bactericidal action of serum against B. typhosus as influenced by unspecific substances. W. PFANNENSTIEL. Westfälische Wilhelms-Universität, Münster. *Z. Immunitäts.* **56**, 389–448(1928).—A study was made of the bactericidal action of serum subjected to many phys. and chem. agents or from animals injected with various types of substances. JULIAN H. LEWIS

The relation of lipoids to proteins and immunity. S BEFANTI. Serotherapeutischen Inst., Milan. *Z. Immunitats.* **56**, 449–63(1928).—A lecture in which it is shown that lecithins from various sources can be split into a toxic substance called lysozithin through the action of a lecithinase found in different animal tissues and fluids. Lysozithin differs chemically from lecithin in the loss of an unsatd. fatty acid mol. It combines with proteins to form a nontoxic compd. These facts are of significance in understanding the role of lipoids in immunity. JULIAN H. LEWIS

The serology of lipoids from carcinoma. HERMANN LEHMANN-FACIUS. Städtischen Krankenanstalt, Mannheim. *Z. Immunitats.* **56**, 464–515(1928).—Alc. exts from human carcinoma contain the heterophilic sheep red-cell antigen. Immunization with these lipoids produces not only the heterophilic amboceptor but also tissue sp. antibodies. JULIAN H. LEWIS

The influence of microörganisms on hemagglutination. MARIO PRATI. Univ. Modena. *Z. Immunitats* **57**, 1–18(1928).—Red blood cells kept exposed to the air for several days show a tendency to clump, an appearance which at times cannot be distinguished from true isoagglutination The exclusion of evaporation as a cause led to the study of bacterial infection as a factor. A large number of bacteria inoculated into a suspension of unagglutinable cells led to this pseudoagglutination. The effect is obtained only after a period in which there is growth of the organisms, and is due to changes in the serum as it takes place only when the red cells are suspended in serum. The low titer of the active substance, the inhibiting effect of lecithin and the impossibility to absorb it from the serum with red cells distinguished it from true agglutinin. This phenomenon is closely associated with the increased sedimenting rate observed in acute infections. Although serum infection lowers the titer of true isoagglutinins the specificity remains unchanged. JULIAN H. LEWIS

The fraction and specificity of serum protein fractions obtained by electroösmosis. R. OTTO AND K. IVANOV. Inst. "Robert Koch," Berlin. *Z. Immunitats.* **57**, 19–41 (1928).—In general there is, with active anaphylaxis expts., a specificity of the globulin and albumin fractions. Between euglobulin and pseudoglobulin a differentiation was not always possible, and less so between sol. and insol. albumin. Active sensitization with the albumin fraction was uncertain even at various incubation periods. With passive anaphylaxis antisera to all fractions showed a species specificity. Serum against euglobulin showed a globulin specificity which permitted a certain separation between pseudoglobulin and euglobulin as the former did not show this specificity. Anti-albumin serum was not specific for albumin. In precipitation expts. anti-euglobulin serum was species and globulin specific. The anti-pseudoglobulin serum reacted to a certain degree with both albumin and euglobulin. One of 2 such sera also reacted with beef serum. The anti-albumin serum reacted more or less species specific but unspecific as to fraction. JULIAN H. LEWIS

Lipoids as complete antigens. KURT MEYER. Rudolf Virchow-Krankenhaus, Berlin. *Z. Immunitäts.* **57**, 42–9(1928).—Lipoid isolated from tapeworms and free

of protein and bacterial infection could act as a complete antigen. In this relation there seemed to be no fundamental difference between the lipoid and protein. The degree of specificity appeared less with lipoid than with protein. J. H. L.

Influence of physico-chemical processes on antibody formation. LEO TAMARI. Inst. "August von Wassermann," Berlin-Charlottenberg. *Z. Immunitäts.* **57**, 85–92 (1928).—An alc. soln. of lecithin and cholesterol suspended in H_2O becomes an active antigen if bivalent cations are added nearly to the isoelectric point. The action of serum in completing the antigenic action of lipoids apparently depends on the ability of the serum to envelop the lipoid particles and thus mask their high electronegative charge. The activity of such protein-lipoid mixts. is made to disappear if the serum-lipoid particles are made electronegative by adding OH ions, and is increased by adding H ions and probably other positive ions. JULIAN H. LEWIS

The relation between the serological reactions of Bordet-Wassermann and Bruck for syphilis. I. L. KRICHEVSKII AND A. J. NEWLER. Mikrobiol. Staatsinst., Rostow a. D. *Z. Immunitäts.* **57**, 93–102(1928).—In order to det. if the antibodies responsible for these 2 types of reactions are the same a large series of sera was tested with the Wassermann reaction using the antigen of Bruck and with the Bruck reaction using the Wassermann antigen. The close agreement in the results of the 2 tests pointed to the identity of the antibodies concerned. JULIAN H. LEWIS

The dependence of chemotherapy and chemoprophylaxis on the reticulo-endothelial system. P. L. RUBINSTEIN. Mikrobiol. Forschungsinst. des Volksbildungskommissariats R. S. F. S. R., Moskau. *Z. Immunitäts.* **57**, 107–29(1928).—The reticulo-endothelial system determines the grade of therapeutic and prophylactic activity of all chemotherapeutic substances. Blockade of the reticulo-endothelial system has very little effect on the therapeutic activity of chemical compds. and does not add materially to the results obtained after splenectomy. JULIAN H. LEWIS

The technic of testing for blood groups. R. FÖRSTER. Universitäts-Hautklinik, Münster i. W. *Z. Immunitats.* **57**, 130–9(1928).—In order to avoid errors in grouping bloods it is advised that each specimen be tested with sera of both types and with red cells of both types. JULIAN H. LEWIS

The diagnosis of smallpox vaccine by complement fixation tests with cocto-antigen. M. LURIE AND M. VOLKOVICH. Bacteriologischen Staatsinstitut, Baku. *Z. Immunitäts.* **57**, 140–5(1928).—Rabbits infected with smallpox vaccine gave a positive complement fixation reaction with the boiled vaccine. JULIAN H. LEWIS

Antigenic properties of lysozyme. T. KIGASAWA. Deut. Univ., Prag. *Z. Immunitats.* **57**, 146–52(1928).—Lysozyme has no regular place of occurrence in plants and animals. There are certain places, as in human tears and egg white, where it is unusually concd. for which fact there is no explanation. No antilysozyme is formed after immunization of rabbits. JULIAN H. LEWIS

Chemospecific antigens. III. The tendency of lipoids to manifest chemospecific antigenic function. A. KLOPSTOCK AND G. E. SELTER. *Z. Immunitäts.* **57**, 174–84 (1928); cf. *C. A.* **22**, 3450.—Lecithin treated with diazotized atoxyl, alkali and acid does not lose its specificity toward antilecithin serum. It reacts stronger with the antiserum, this change being due to the treatment with alkali and acid and not to the diazotized atoxyl. The atoxyl-treated lecithin shows chemo-specificity in that an antiserum obtained by injecting rabbits with it reacts to atoxyl-lecithin but not to metanilic acid-lecithin. The atoxyl-lecithin combination is formed if the 2 substances are mixed at neutral reaction or at an alkaline reaction and afterward made acid. JULIAN H. LEWIS

Antibody formation in lipoid-fed animals. L. SURÁNYI. Bacteriol. Inst. der Kgl. ungar. Pázmány-Péter Univ., Budapest. *Z. Immunitäts.* **57**, **185(1928)**. See *C. A.* **22**, 3221. JULIAN H. LEWIS

The influence of lipoids on toxin action. L. SURÁNYI AND L. JARNO. Bacteriol. Inst. der Kgl. ungar. Pázmány-Péter Univ., Budapest. *Z. Immunitats.* **57**, 199–204(1928).—Cholesterol protects animals against diphtheria, tetanus and botulinus toxins. Lecithin delays the fatal action of diphtheria toxin but hastens that of tetanus. JULIAN H. LEWIS

The augmentive action of lecithin on complement-fixation reactions. KEHNOSUKE YASUI. Inst. für experimentelle Krebsforschung, Heidelberg. *Z. Immunitäts.* **57**, 205–18(1928).—Lecithin increases the antigenic action of bacterial lipoids as antigens in complement fixation tests (Dienes and Scheff, *J. Immunol.* **13**, 161(1927)). This action depends on the effect on the bacterial lipoids and is not due to any antigenic action of lecithin. The action of lecithin is dependent on the manner of mixing of the components, the best results being obtained by mixing the alc. solns. of bacterial lipoid

and lecithin and dilg. with salt soln. The antigenic action of organ alc. exts., serum and bacterial suspension are not influenced by lecithin. Tubercle bacilli, however, are affected because of their high content in lipoid. The pseudo-antigenic action of morphine is increased with lecithin. This reaction is distinguished from a true antigenic action in that the former does not take place at 0°, while the latter does.
JULIAN H. LEWIS

Thrombocytobarin. I. KRICHEVSKII AND R. CHERIKOVER. Mikrobiol. Forschungsinst. des Volksunterrichtskomissariats R. S. F. S. R., Moskau. *Z. Immunitäts.* **57,** 234–60(1928); cf. *C. A.* **20,** 1460.—Killed spirochetes do not produce thrombocytobarin since they have no antigenic function. Immunization with living organisms regularly produce the antibody. Spirochetes heated to 45–56° can absorb thrombocytobarin but do not exhibit the phenomenon of attracting platelets. This is thought to be due to physico-chem. changes and not to the loss of motion or reproduction. Thrombocytobarin is found in the globulin, particularly the pseudoglobulin fraction of rat blood. The failure of spirochetes to attract platelets in serum obtained by clotting as contrasted with serum obtained by defibrination is due to the smaller amt. of complement and thrombocytobarin in the former. Thrombocytes cannot be substituted with bacteria or positively or negatively charged particles in the so-called "Beladungs" phenomenon, although functionally similar cells of other species can be substituted with help of thrombocytobarin. JULIAN H. LEWIS

Studies on tetanus toxin, ricin and several alkaloids and their detoxification. JOHANN SCHUBERT. Inst. fur exptl. Therapie des allgem. Krankenhauses, Hamburg-Eppemdorf. *Z. Immunitats.* **57,** 261–84(1928).—The effect of numerous substances, including amino acids, alkali, lipoids and bacteria, on these toxic substances are studied No general grouping of results can be given. JULIAN H. LEWIS

Comparative action of digestive enzymes on the intracutaneous reactivity and flocculation action of old tuberculin. S. FICHERA Sanatorium Ferrarotto, Catania *Z. Immunitats.* **57,** 285–6(1928).—After pepsin and trypsin digestion the intracutaneous reactivity of old tuberculin is influenced quicker than is the flocculation action. With gastric juice the difference is less and the intracutaneous reactivity remains unaffected longer than the flocculation reaction. JULIAN H. LEWIS

The relation between the Thomsen phenomenon and cold agglutination. LEONE LATTES AND CARLO CREMA. Konigl. Universitat, Modena *Z Immunitats.* **57,** 287–91(1928). JULIAN H. LEWIS

The relation of chemotherapy and chemoprophylaxis to the reticulo-endothelial system of the rat. A. V. LISGUNOVA. Mikrobiol. Forschungsinst. des Volksbildungskommissariats R. S. F. S. R., Moskau. *Z. Immunitats.* **57,** 292–300(1928).—From a comparison of the therapeutic and prophylactic action of germanin, neoarsphenamine, tryparosan and trypan red in normal and splenectomized rats after infection with trypanosomes it is concluded that the reticulo-endothelial system has no protective action itself but that it activates the chemotherapeutic agents to greater efficiency.
JULIAN H. LEWIS

Irregularities in the Landsteiner blood groups. OLUF THOMSEN. Inst fur allgemeine Pathol. der Universitat, Copenhagen. *Z. Immunitats* **57,** 301–19(1928).—The departures made by various authors from the grouping of red cells as given by Landsteiner is due to the occurrence of defective groups, in which there is an agglutinin missing, and to the failure to recognize the so-called "cold agglutinins." J. H. L.

The specificity of fibrin. HANS J. FUCHS. Inst "August von Wassermann, Berlin. *Z. Immunitäts.* **57,** 320–5(1928).—Fibrin from the plasma of a rabbit immunized with sheep red cells and produced by the action of prothrombin from this immunized animal contains amboceptor and thrombin. If coagulation is induced with prothrombin from a normal rabbit, the fibrin contains no amboceptor but does contain thrombin. Since amboceptor and thrombin are obtained by extn. with 8% salt soln. and not with distd. H_2O it is indicated that the 2 substances are chemically bound and not merely adsorbed. The ppt. obtained from oxalate plasma with K_3PO_4 contains prothrombin and amboceptor, both of which can be freed with CO_2. Thrombin solns. obtained from fibrin contain no complement. JULIAN H. LEWIS

The role of conditional reflexes in immunity. S. METALNIKOV AND V. CHORINE. Inst. Pasteur, Paris. *Z. Immunitäts.* **57,** 326–36(1928).—A bacterial emulsion was injected intraperitoneally into guinea pigs daily for 15–25 days. Each injection was accompanied by some external stimulus such as scratching or applying heat to the skin. After a period of recovery from the injections it was found that an application of the external stimulus without an accompanying injection produced cellular changes in the peritoneal fluid similar to those produced by the bacterial emulsions. The phe-

nomenon of conditional reflex studied by Pavlov in connection with physiological reactions is thus found to be applicable to immune phenomena. J. H. L.

The titration of the antigenic property of diphtheria toxoid with the Ramon flocculation method. E. Hoen and L. Chertkov. Staatlichen Bakteriol. Inst., Odessa. *Z. Immunitäts.* **57**, 337–46(1928).—The point of disappearance of flocculation cannot be taken as the titer of the antigenic action of diphtheria toxin and toxoid as advocated by Ramon, nor is the titer obtained by taking the time of the deposit of flocculi confirmed by *in vivo* tests. The time of the appearance of flocculation depends not only on the characteristics of each toxin and toxoid but also on those of the antiserum used for testing. Although toxins and toxoids with high antigenic strength flocculate in general rapidly there are also those with a low antigenic power which flocculate very rapidly. In contrast to the flocculation method the ring pptn. method gives results of more regularity which agree with the proved antigenic strength. J. H. L.

Observations on the Rickenberg-Brussin reaction in relapsing fever of man. V. M. Aristovskii and E. P. Schaechter. Staatlichen Univ., Kasan. *Z. Immunitäts.* **57**, 347–56(1928).—The artificial infection of patients with a culture of *sp. obermeieri* stimulates the formation of the substances responsible for the Rickenberg-Brussin reaction The plasma or the serum from spontaneous coagulation of blood taken the next day after the fall of temp. can be used for the test. As a source of platelets, which in positive reactions clump around the spirochetes, plasma from another species must be used as those of human plasma are not adapted to the reaction. A series of observations lead to the conclusion that the antibody responsible for this reaction and lysin for spirochetes are identical substances Julian H Lewis

Experimental-morphologic studies on the role of the lungs, liver and spleen in fat and lipoid metabolism. C. L. Derman and Samuel Leites *Virchow's Arch. path. Anat.* **268**, 440–55(1928).—After enteral and parenteral introduction of oleic acid in dogs• fatty acids can be found in the lungs, liver and spleen, mixed with neutral fat and lipoids On feeding olive oil, neutral fat becomes visible, particularly in the alveolar epithelium of the lung, the hepatic and Kupffer cells and the reticulo-endothelium of the spleen. In the liver and spleen fatty acids are also found. They may be found in the lungs likewise if previously the spleen has been removed or the reticulo-endothelial system blockaded. After feeding cholesterol in olive oil, cholesterol and its esters are found in the lungs, liver and spleen. After parenteral introduction of this mixt., cholesterol is not found in the lungs and liver, which show the presence only of a mixt. of neutral fat and fatty acids. After feeding lecithin and injecting it, it cannot be found as such in the lungs, liver or spleen; histochemically only its split products, neutral fat and fatty acids, can be discovered. The capacity of the lungs, liver and spleen to split fats and lipoids, thus shown, indicates their importance in lipoid metabolism. E. R. Long

Factors in the calcification of animal tissues. Hans Kleinmann. Univ. Berlin. *Virchow's Arch. path. Anat.* **268**, 686–750(1928) —Tissue calcification may be classified in 3 groups: (1) that dependent on disturbance in Ca metabolism, such as variation in the Ca and PO_4 ions in the tissue fluids; (2) that dependent on depression of cellular activity or complete tissue death; and (3) that resulting from a hypothetical special cell activity, seen only in bone growth. In the first group particular substances occasion the deposition of Ca salts; or, conversely, the disappearance of substances normally preventing the deposition may permit its occurrence. The existence of the second group depends on the fact that a reduction of the normal CO_2 production may lead to a deposition of Ca in tissues through reduction in acidity. It is still problematical why Ca tends to be deposited in greater part as phosphate and lesser as carbonate. K.'s expts. indicate that the important factor is a local increase of Ca and PO_4 in the calcifying tissues to a point where the limit of solubility of the product is exceeded. Decrease in the acidity of the tissue in acid-excreting organs may add to the effect of this factor. To a certain extent the pptd. phosphate is replaced by the carbonate of the tissue juices. It is immaterial for calcification whether the local increase in Ca and PO_4 is due to increased local intake or decreased outgo. •

E. R. Long

General hemochromatosis. Kurt Bork. *Virchow's Arch. path. Anat.* **269**, 178–208(1928).—The hemosiderosis of general hemochromatosis is not due to increased blood destruction, but is rather the result of an impaired prepn. and storage as well as a decreased excretion of Fe. The disturbance in Fe metabolism and associated disturbance of protein metabolism are the expression of a toxic cell injury. The deposited Fe pigment is of itself injurious, but the lesions of hemochromatosis are in part due to the associated toxic substances. There are border-line cases closely allied

to hemochromatosis and occasionally pernicious anemia and leucemia are associated with the abnormality. E. R. LONG

Parenteral denaturization of foreign proteins. I. Effect on sensitizing power. W. H. MANWARING, H. D. MARINO AND J. L. AZEVEDO. Stanford Univ. *J. Immunol.* 15, 109-13(1928); cf. *C. A.* 22, 1389.—Titrations by means of rabbit precipitin indicate that horse proteins injected intravenously into normal dogs are retained in the circulation at least 10 days, but transfusions from these dogs into normal recipients show that these proteins are so altered by the seventh day as almost completely to lose their sensitizing power. Parenteral sensitization may be an initial stage in antibody formation. **II. Denaturization rate in immune dogs.** W. H. MANWARING, H. D. MARINO, J. L. AZEVEDO AND H. C. TORBERT. *Ibid* 351-4.—The rate of parenteral denaturization of horse proteins in horse serum-immune dogs is distinctly slower than in normal dogs. There is not the rapid denaturization previously observed in hypersensitive dogs. This finding supports the view that the sp. antibodies in hypersensitive and immune dogs are not identical. E. R. LONG

Carbon dioxide studies. II. The preservation of alexin in various gaseous environments with special reference to carbon dioxide. GEORGE VALLEY AND JAMES G. MCALPINE. *J. Immunol.* 15, 313-24(1928).—Of several gases employed, including N_2, CO_2, H_2 and air, CO_2 alone exerted a pronounced preservative action on serum alexin. When enclosed in a CO_2 atm. in an air-tight container, alexin may be preserved for 3-5 weeks without loss of potency, and possibly for months. A simple downward displacement of atm. air by a stream of CO_2 is all that is required in making the preservation. **III. Preservation of alexin in carbon dioxide: the nature of the alexin preservation.** GEORGE VALLEY. Yale Univ. *Ibid* 325-34.—The preservative action of CO_2 gas on alexin is in all probability due to the establishment and maintenance of conditions which favor reduction and prevent oxidation. $Na_2S_2O_4$ reactivates alexin which has undergone spontaneous deterioration. "Deoxygenation" effected by several hours' contact with CO_2 gas accomplishes the same result.
E. R. LONG

Effect of exposure to low temperature on diphtheria toxin-antitoxin mixtures. ELLIOTT S. ROBINSON AND BENJAMIN WHITE. *J. Immunol.* 15, 381-94(1928).—There is no satisfactory explanation at present for the increase in toxicity of samples of toxin-antitoxin mixts. after freezing. There is enough evidence to indicate that the phenomenon does occur. Among the contributing factors are (*a*) the persistence of low temps., (*b*) during more than a min. period, (*c*) acting upon toxin-antitoxin mixts. of certain concns., (*d*) contg. phenol or tricresol and certain factors still undetd. The phenomenon appears to be due to a dissocn. of toxin and antitoxin, rather than a destruction of the antitoxin. E. R. LONG

A study of antibodies in their relation to globulins in the cerebrospinal fluid. ALFRED FLAUM. Inst. Path. Lund. *Acta Path. et Microbiol. Scand.* 5, 16-24(1928).—Pandy's reaction was frequently negative in rabbit spinal fluids contg. antibodies produced by exptl. local immunization. This proves that antibodies can exist independently of globulins, at least in spinal fluid. E. R. LONG

The identity of the precipitinogenic and antitoxin-binding substance in diphtheria toxin. E. HOEN, L. CHERTKOV AND V. ZIPP. *Z. Hyg. Infektionskrankh.* 108, 61-5(1927).—Physical and chem. methods failed to detect a difference between the toxic and precipitinogenic substances in diphtheria toxin. A range of H ion concn. borne by the one was equally well tolerated by the other. E. R. LONG

Composition of bone. II. Pathological calcification. M. J. SHEAR AND BENJAMIN KRAMER. Jewish Hosp., Brooklyn, N. Y. *J. Biol. Chem.* 79, 121-3(1928).—Seven specimens of pathol. calcified tissues (thyroid, tuberculous lymph nodes, cusp of aortic valve, capsule of spleen, lung lymph node, mesenteric lymph node and a chalk deposit in a fibroid) all gave normal values (1.88 to 2.01) for the ratio residual Ca:P when analyzed by the new micro-technic. Abnormal values of 2.23 and 2.18 were obtained in analyses of calcified fibroids of the human uterus. A. P. L.

The effect of parathyroid extract on mineral metabolism in infantile tetany. ALFRED T. SHOHL, A. M. WAKEMAN AND E. Y. SHORR. Yale Univ. *Am. J. Diseases Children* 35, 392-7(1928).—Infantile tetany appears to be characterized by an abnormal K metabolism. Na and K are excreted in normal amts. during the administration of parathyroid ext. in tetany, but when the treatment is discontinued, an excess of Na is excreted and K is retained. This is not in accordance with Greenwald's Na theory (*C. A.* 17, 137).
E. R. MAIN

The volume of the blood. II. The volume of the blood and concentration of electrolytes in dehydration and edema. DAN C. DARROW AND THOMAS E. BUCKMAN.

Am. J. Diseases Children **36**, 248–67(1928).—The diminution in the vol. of blood plasma of infants, which occurs both in dehydration and in edema, is not due simply to a transfer of water from the blood. The concn. of blood crystalloids and electrolytes is only slightly affected by changes in the plasma vol. Variations in the concn. of serum proteins and in the vol. of red corpuscles are not necessarily paralleled by changes in the plasma vol. E. R. MAIN

Blood fat in diabetic children. GLADYS L. BOYD. Univ. of Toronto. *Am. J. Diseases Children* **36**, 298–309(1928).—The fat content of the blood plasma is usually above the normal in diabetic children and reaches values of 1000 mg. or more per 100 cc. of blood during acidosis and ketosis, and of 2000 mg. per 100 cc. during coma. A rapid increase in the fat content of the blood may indicate the existence of an incomplete fat combustion and of incipient acidosis. There is no const relationship between the concn. of blood fat and that of blood sugar, but an increase in tolerance to sugar is usually assocd. with a tendency toward a maintenance of the concn. of blood fat at a normal level or with a reduction of an abnormally high fat concn. The concn. of blood fat may be increased by a diet sufficiently high in caloric value to produce overweight. There appears to be no correlation between the fat content of blood and its turbidity. E. R. MAIN

The physiology of the surviving mammalian heart. IV. The consumption of sugar by the heart of diabetic (depancreatized) cats, and the influence of insulin on the sugar consumption of such hearts. ZOLTÁN ASZÓDI. *Biochem. Z.* **192**, 14–25 (1928).—Hearts from depancreatized cats use measurable amts. of sugar though much less than those from normal animals. A single insulin dose increases the heart's sugar consumption to the normal level. This is also true of hearts from normal cats receiving a single insulin dose, and their sugar consumption is raised. S. MORGULIS

The causes of rapid death of diabetic (depancreatized) cats. ZOLTÁN ASZÓDI. *Biochem. Z.* **192**, 26–35(1928).—High blood urea values are found alongside with high sugar values. The administration of insulin which greatly reduces the hyperglucemia has practically no effect on the blood urea level. This explains why diabetic coma without acidosis ends fatally in spite of the beneficial effect of the insulin. S. M.

Chemical composition of the blood in lipemia following hermorrhage. ELLA H. FISHBERG AND ARTHUR M. FISHBERG. *Biochem. Z.* **195**, 20–7(1928).—Removal of 35 cc. blood daily produces lipemia in rabbits. The increase in fat and cholesterol in the blood results from the loss of serum protein, especially albumin. The diminution in serum protein calls forth a compensatory mobilization of body fat in the effort to maintain the normal level of colloidal osmotic pressure. S. MORGULIS

The role of fat in the human organism (in starvation and in tuberculosis). V. H. STEFKO. Inst. für Tuberkuloseforschung, Moskau. *Biochem. Z.* **195**, 396–402(1928).—A diminution in I no. of the subcutaneous and deeper fat tissue has been noted in starved and tuberculous individuals. S. MORGULIS

Chemistry of fattening of liver. A. GUBSER. Inst. für Hochgebirgsphysiologie und Tuberkuloseforschung, Davos. *Biochem. Z.* **198**, 65–80(1928).—Fattening of the liver due to either reduced pressure or to P poisoning is marked by a high phosphatide content, whereas in fattening due to overheating or to $CHCl_3$ poisoning the phosphatide content is not above normal. Fatty degeneration, therefore, does not represent chemically a simple process. In the phosphatide-rich liver the total P does not exceed normal values, the phosphatide P being in greater proportion. The phosphatide must therefore be formed from substances present in the liver itself, probably through a transformation of nuclein P into phosphatide P. S. MORGULIS

The pathogenesis and treatment of dyspnea in the light of recent experiments. C. S. DANZER. Columbia Univ. *Ann. Internal Med.* **2**, 239–47(1928).—If an animal is placed in an atm. contg. 10% of CO_2, it will develop an increased blood velocity followed by cardiac hypertrophy. The animal will live indefinitely because the buffering mechanism neutralizes the excess CO_2 taken up by the blood. If the animal is given a staphylococcus or a streptococcus infection, it will be killed by such exposure to CO_2 in 30 min. with signs of acidosis. Apparently infection impairs the buffer mechanism. This may explain dyspnea on exertion without apparent heart disease, by postulating that the buffer mechanism is impaired. In many instances, therefore, alkalies may relieve the heart. JOHN T. MYERS

The influence of the tropics on rickets. ROGER BROOKE. U. S. A. Fort Sam Houston. *Ann. Internal Med.* **2**, 281–8(1928).—About 25% of children in the tropics have mild rickets. A diet poor in sterols is a minor factor. Long wet seasons with high humidity is important. JOHN T. MYERS

Studies in intestinal obstruction. IV. Strangulation obstruction: a comparison

of the toxicity of the intestine and other tissues autolyzed in vitro and in vivo. OWEN H. WANGENSTEEN AND GEORGE W. WALDRON. Univ. of Minn. *Arch. Surg.* **17**, 430–9(1928); cf. *C. A.* **22**, 3217.—The products of disintegration of intestine were markedly toxic when segments of small intestine were allowed to autolyze in the peritoneal cavity or when rats were given intraperitoneal injections of the products of autolysis of intestine from sterile containers kept in the incubator. When various tissues were allowed to autolyze in the peritoneal cavity, there was a marked increase in the urinary excretion of N, but only a slight increase of the non-protein N of the blood. The low values for blood chlorides seen in dogs with obstruction of the upper part of the intestine were not obtained in strangulation of the intestine alone (closed loop obstruction with gangrene), when the continuity of the remainder of the intestinal tract was restored. The subcutaneous administration of saline to animals with disintegrating segments of intestine appeared to be valueless. JOHN T. MYERS

Antigen structure and immunizing power. SACHS. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104**, 128–40(1927).—The chem. structure of an antigen is the decisive factor in its sp. immunizing power. JOHN T. MYERS

Discussions of active immunity. The action of complex antigens. A. KLOPSTOCK AND G. E. SELTER. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104**, 140–3(1927).—Mixts. of atoxyl and lecithin could bind complement in the presence of serum immune either to lecithin or to ox serum which had been treated with atoxyl. Serum components treated separately with atoxyl produced chemo-sp. antibodies, not only for complement fixation but for anaphylaxis. This is important in the study of the biochemistry of antigens and of idiosyncrasies. JOHN T. MYERS

Cholera toxin and antitoxin. HAHN AND HIRSH. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104**, 211–2(1927).—The cholera vibrio produces a sol toxin in 8-hour cultures which increases in concn. up to 3 days. By the immunization of horses a practical therapeutic antitoxin can be produced. JOHN T. MYERS

Experimental studies in bacterial hemolysins. W. KOLLATH AND GERT TAUBMANN. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104**, 252–6(1927).—There is a parallelism between the formation of a turbid zone around colonies on ascites agar and hemolysis on blood agar plates. This zone on ascites agar no longer stained with Sudan III, as did the remainder of the plate; hence the organism must produce a lipase. This same lipase may destroy the lipoids in the membrane of the erythrocyte, thus causing hemolysis. JOHN T. MYERS

Sensitizing properties of toxoid (anatoxin). BACHER. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104**, 150–2(1927).—Anatoxin will immunize children with very little anaphylactic sensitization; hence large immunizing doses can be given to Schick positive cases. JOHN T. MYERS

Prophylactic immunization against diphtheria with toxoids. KUNDRATITZ. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104**, 152–5(1927).—The toxoids of Ramon are of practical value in diphtheria prophylaxis because they are harmless, and because of the certainty of their immunizing effect. JOHN T. MYERS

The detoxication of endotoxins. LUBINSKI. *Centr. Bakt. Parasitenk. I Abt. Orig.* **104**, 155–7(1927).—The addn. of 0.4% of formalin can decrease the toxic effect of endotoxin without interfering with its immunizing power. This may be due to the hardening effect of HCHO on the bacterial cell which would make absorption slower. This may permit the substitution of a single large dose for the series of injections used for typhoid or cholera inoculations. JOHN T. MYERS

The biological properties of Besredka filtrates. II. The immunizing power of staphylococcus filtrates. G. S. BARG. Bact. Inst., Kiew. *Centr. Bakt. Parasitenk. I Abt. Orig.* **108**, 341–52(1928); cf. *C. A.* **22**, 4144.—Intracutaneous injection of staphylococcus filtrates raises the resistance of guinea pigs to injections of live cultures of staphylococci when given subcutaneously in the same location within about 48 hours. However, the opposite occurs if a large no. of intracutaneous injections of filtrate are given. Intracutaneous injection of sterile bouillon also increases local resistance. Local irritation of the skin, as close shaving, raises local resistance to subcutaneous injections of live staphylococci. JOHN T. MYERS

Hemoglobin resistance. FRIEDA ROSOWSKY. Stadt Krankenhause Berlin-Neukölln. *Folia Haematol.* **36**, 342–51(1928).—By hemoglobin resistance (HR) is meant the no. of sec. required for the disappearance of the oxyhemoglobin line in the spectrum, after the addn. of alkali in the following procedure: Mix 0.1 cc. of a 10 or 20% aq. soln. of blood with 0.1 cc. of 0.1 *N* HCl. Heat on a water bath at 50° to 60° for 10 min., cool and mix with distd. water till it matches a standard color tube. To each 5 cc. add 1 cc. of 0.25 *N* NaOH. In 12 cases of infectious icterus there was no

change in HR. In only 1 of 8 cases of pernicious anemia was there an increase. In one of 5 cases of secondary anemia there was a slight decrease. The differences were never of sufficient degree to give the method any diagnostic value. There is a bibliography. JOHN T. MYERS

Blood groups in horses from the point of view of blood transfusion. KARL SANDNER. *Folia Haematol.* **36,** 366–76(1928).—Incompatibility occurred only 17 times in 2000 trials with 115 horses. Five combinations of agglutinin and agglutinogen were found: AO, B anti A, O anti A, O anti B and AB. No sp. combination for any breed was found. No isohemolysins were observed. JOHN T. MYERS

Toxic granules of neutrophilic leucocytes and their practical significance. ELIAS MATIS. Der I. med. Klinik, Charité (Berlin). *Folia Haematol.* **36,** 398–423(1928).—Toxic or abnormal granules can be demonstrated by the carbol-methylene blue method of Freifeldt as follows. The blood film is fixed for 3 min. in MeOH, placed in a mixt. of distd. water 20 cc., soln. I 7 drops and soln. II 5 drops, and allowed to stand for 1 to 1.5 hrs. at room temp. Soln. I is basic fuchsin 1 g., hot abs. alc. 15 cc., and distd. water 100 cc. Soln. II is 1% aq. methylene blue. In 12 normal bloods there were no toxic granules. They were absent in 29 cases of non-infectious diseases. They were present in all of 24 cases of severe infectious diseases. They were present in 34 out of 39 cases of active pulmonary tuberculosis. They were present in 10 out of 18 cases of mild infectious diseases. In general the size of the granules parallels the severity of the infection; hence their demonstration is useful in diagnosis and prognosis. The disadvantages of the method are: the difficulty of making uniform stains, the time required in making the stain, and the failure of the technic in about 20% of the attempts. JOHN T. MYERS

The occurrence of multiple zones in the serum precipitation reaction. NIEL E. GOLDSWORTHY. Univ. of Cambridge. *J. Path. Bact.* **31,** 525–39(1928).—Twenty-five sera obtained at different stages during the immunization of 9 rabbits against horse serum were tested. Of these, 6 showed but one zone of particulation, and of the 6, 3 showed faint or doubtful indications of a secondary zone. Twelve samples showed 2 definite zones and 3 of these gave uncertain indications of a tertiary zone. Seven samples showed 3 zones of particulation and one of these had a suggestion of a 4th zone. Hence multiple zones occur rather commonly. Mixts. in which the amt. of antigen is more than optimal are more apt to show supernumerary zones. JOHN T. MYERS

Observations on the part played by alcohol in the Wassermann reaction. C. H. BROWNING AND E. M. DUNLOP. Univ. and Western Infirmary, Glasgow. *J. Path. Bact.* **31,** 541–7(1928).—In the Wassermann test when heated sera are used, differences in the complement fixing power of ext emulsions which vary in alc. content are usually directly related to the alc. concn. Increase in the concn. of alc. is not, however, associated with any regular and definite increase in sensitiveness when tested with many sera, but is manifested with only a few. JOHN T. MYERS

The gastro-intestinal flora in pernicious anemia. L. S. P. DAVIDSON. Univ. of Edinburgh. *J. Path. Bact.* **31,** 557–82(1928).—There is no evidence that bacterial toxins are of etiological significance in pernicious anemia. The quant. increase of bacteria at different levels of the small intestine is significant, but there is no evidence of any sp. single species. There is a good bibliography. JOHN T. MYERS

The effect of certain liver extracts upon the survival of parathyroidectomized cats. M. M. GORBUNOVA. State Inst. Exptl. Med., Leningrad. *Arkh. Biol. Nauk* **28,** 37–9(1928).—Parathyroidectomized cats receiving liver exts. and perfusion liquids of isolated livers failed to survive longer than the control animals, all of them dying after about the same time with symptoms of tetany. W. A. PERLZWEIG

Prolonged experiments with intravital staining in rabbits. M. I. GESSE. State Inst. Exptl. Med., Leningrad. *Arkh. Biol. Nauk* **28,** 235–59(1928).—Daily injections during 4–12 months were carried out on 14 rabbits with carmine, trypan blue and India ink, and the tissues were examd. histologically. No qual. differences were observed in the end results with carmine as between shorter and longer expts. After 10 months of trypan blue treatment large deposits of the dye were found generally distributed in the cells of the reticulo-endothelial system, particularly in the liver, spleen, spinal cord, lymph nodes and connective tissue. Smaller deposits were found also in the epithelium of the biliary vessels, cartilage, renal tubules, endothelium of the eye, cornea and the smooth muscles. Injection of India ink during 1 year led to the formation of great deposits in the reticular endothelium of the liver, spleen and spinal cord, much less in the lymph nodes. In all of these organs, and especially in the lungs and in the renal glomeruli, many macrophages were found causing capillary emboli. Granules of all

of the dyes were also found in the epithelial cells of the liver. Not a grain of these substances was found in the reticulo-endothelial cells which were newly formed.

W. A. PERLZWEIG

The influence of the thyroid gland upon the development and the course of diabetes. V. G. BARANOV. State Inst. Exptl. Med., Leningrad. *Arkh. Biol. Nauk* **28,** 275–83 (1928).—The administration of thyroid ext. to partially pancreatectomized dogs either brought on or intensified glucosuria and polyuria. In other partially pancreatectomized dogs the ablation of one thyroid caused a temporary disappearance of glucosuria, while the ablation of the remaining thyroid caused a complete cessation of glucosuria, which returned upon the administration of thyroid ext. In other animals thyroidectomy did not bring about the same results. The thyroid is believed to exercise a modifying effect upon the function of the pancreas but no direct effect upon carbohydrate metabolism.

W. A. PERLZWEIG

Studies concerning the influence of a disturbance of the acid-base equilibrium of the blood on renal function and pathology. Study IV. The protection of the kidney against the injury from uranium nitrate by the use of sodium bicarbonate. Part 1. The protection of the acutely nephropathic kidney. Part 2. The protection of the kidney in which an acute nephropathy has been superimposed upon a chronic naturally acquired glomerulonephropathy. W. DEB. MACNIDER. Univ. of N. C. *J. Metabolic Research* **7–8,** 1–28(1925–26); cf. *C. A.* **18,** 2556–7.—The expts. were carried out on dogs. Conclusions: The nephrotoxic action of U nitrate is largely due to its ability to induce and maintain a disturbance in the acid-base equil. of the blood which is furnished the kidney and in which altered blood chem. environment this organ must attempt to functionate in a normal manner. In certain animals acutely nephropathic from U nitrate the use of $NaHCO_3$ maintains this equil. of the blood. In such animals there is less evidence of renal injury and a more perfect maintenance of renal function. In other acutely nephropathic animals and in all the animals with a natural acquired glomerulonephropathy in which an acute injury has been superimposed on the chronic process, the use of $NaHCO_3$ has been unable to maintain this equil. In such animals there was a marked disturbance in both the functional response of the kidney and in the histologic preservation of the kidney.

W. A. PERLZWEIG

Treatment of diabetic acidosis. S. H. KAHN AND W. H. OLMSTEAD. *J. Metabolic Research* **7–8,** 29–35(1925–26).—A clinical discussion of the various types of diabetic acidosis and of its treatment.

W. A. PERLZWEIG

Lactic acid content of pathological discharges. R. SCHELLER. *Munch. med. Wochschr.* **73,** 1879–81(1927); *Chem. Zentr.* **1927,** I, 3100.—Pleural transudates have the same lactic acid and sugar contents as the blood. In sterile lymph and leucocytic effusions the lactic acid content varies from 17 to 32 mg. %. In purulent pleural infections and in a tumor exudate the complete disappearance of glucose and high lactic acid values were found. In ascitic fluids of tumor cases high lactic acid and normal sugar values were observed. Transudates and exudates of the pleura as well as ascitic fluids show no evidence of glucolysis as long as purulent processes are absent.

W. A. PERLZWEIG

Hemolysis of chicken blood. G. E. SHATTUCK. New York Univ. *J. Gen. Physiol.* **12,** 17–28(1928).—Saponin and Na taurocholate cause hemolysis of nucleated chicken erythrocytes but leave the nuclei and "ghosts" in suspension, thereby making the end point of hemolysis difficult to read. The time-diln. curves of hemolysis with these compds. are of the same nature as those for hemolysis of non-nucleated cells. Na oleate causes hemolysis and in stronger solns. karyolysis of the erythrocytes. Viscosity changes are found in the lysin-cell system with strong concns. of Na taurocholate and Na oleate. The action of these lysins on the nucleated erythrocytes is apparently similar to that on non-nucleated erythrocytes.

C. H. RICHARDSON

Complement interference—a new explanation for the Neisser-Wechsberg phenomenon. ROSCOE R. HYDE. Johns Hopkins Univ. *Am. J. Hyg.* **8,** 730–9(1928).—The expts. support the following propositions: (*a*) Hemolysis is dependent upon the order of addn. of the complement components to the reacting system under certain temp. conditions. (*b*) The sensitized corpuscle absorbs a complementing property from the deficient guinea-pig serum at a warm temp. (*c*) The sensitized cell does not absorb the heat-resistant complement component from human serum. (*d*) The sensitized corpuscle that has been exposed to the complement components in the deficient serum will remove the third complement from the heat-inactivated serum at a warm temp. The evidence indicates that the prezone which results with excessive quantities of immune serum is due to the amboceptor, in the sense that this reagent supersensitizes the antigen, so that the complement components are attracted to the cell out of the order

necessary to effect their destruction. Excessive quantities of amboceptor deflect the complement indirectly through its union with the antigen; so that under proper temp. conditions its affinity for the complement components is changed and they are taken on the cell out of the order necessary to effect the destruction of the sensitized cell. Alexin consists of at least 3 components, and it appears that this reagent may be destructive to the sensitized cell in one order of addn., while in a changed order a protective action is effected. L. W. RIGGS

Insulin does not increase the fixation of blood sugars by the corpuscles. Refutation of the notion of glycemine. G. FONTES AND L. THIVOLLE. *Compt. rend. soc. biol.* **98,** 847–9(1928); cf. Haüsler and Loewi, *C. A.* **19,** 2674; **20,** 1470; **21,** 1149.—The conclusions in this study are contrary to those of Haüsler and Loewi, and are in agreement with those of Hedon, cf. *C. A.* **22,** 2204. L. W. RIGGS

Apropos the paper by L. Kepinov and S. Petit-Dutaillis on the influence of diabetic blood on the glucemia of the dog and the rabbit. F. RATHERY AND R. KOURILSKY. *Compt. rend. soc. biol.* **99,** 528(1928); cf. Kepinov, *C. A.* **22,** 3927.—Tests with 12 normal dogs and 2 rabbits by injection of human or animal diabetic blood led to no const. results. L. W. RIGGS

Influence of injections of "Wasserblau" on the development of antitoxic immunity in the guinea pig. DONALD FRASER. *Compt. rend. soc. biol.* **99,** 561–2(1928).—Under the exptl. conditions the injection of strong doses of "Wasserblau" before or during immunization by anatoxin neither prevents nor establishes sp. immunity, nor the production of diphtheria antitoxin. L. W. RIGGS

Mechanism of the action of the liver in the treatment of pernicious anemia by the method of Whipple. M. WEINBERG AND J. ALEXA. *Compt. rend. soc. biol.* **99,** 567–9 (1928). L. W. RIGGS

Bactericidal properties of pleural and peritoneal exudates of tuberculous subjects. YEVREM NEDELKOVITCH. *Compt. rend. soc. biol.* **99,** 579–81(1928).—Pleural and peritoneal exudates of tuberculous subjects act on bacilli of tuberculosis *in vitro* in a manner to prevent their development on culture media. Heating even to boiling did not destroy this property. L. W. RIGGS

Composition of the blood with reference to the menstrual cycle. I. Cholesterol. CH. O. GUILLAUMIN AND HENRI VIGNES. *Compt. rend. soc. biol.* **99,** 618–20(1928).— **II. Lecithin.** *Ibid* 620–2.—An attempt was made to relate the variations of the cholesterol and lecithin contents of the blood as functions of the duration of the menses, the duration of their interval and the date of the menstrual month in patients with benign gynecologic affections. L. W. RIGGS

Effect of cod-liver oil on the delayed coagulation time following experimental jaundice. JOHN C. BROUGHER. Univ. Oregon. *Science* **68,** 256–7(1928).—In expts. with 9 dogs cod-liver oil in doses of 30 cc. in 300 to 400 cc. of water by stomach tube consistently changed a delayed coagulation time in obstructive jaundice to normal. The efficacy of cod-liver oil in causing this change is probably based on its ability to increase the ionizable Ca. L. W. RIGGS

The iodine content of the soil, water and of some foods in regions afflicted with goiter. F. MEINCK. *Kl. Mitt. Ver. Wasserversorg Abwässerbeseitig.* **3,** 10–1; *Chem. Zentr.* **1927,** II, 1884.—Data are given for 4 communities in the Taunus (Germany). G. SCHWOCH

Changes in acid-base equilibrium in inflamed tissue. F. BRICKER AND F. SUPONITZKA. *Arch. exptl. Path. Pharm.* **133,** 103–6(1928).—No acidosis is to be found provided the circulation to the inflamed area remains unimpaired. G. H. S.

Effect of the central nervous system upon the processes of immunity. III. Relation of the sympathetic to the occurrence of agglutination. L. BOGENDÖRFER. Univ. Würzburg. *Arch. exptl. Path. Pharm.* **133,** 107–10(1928); cf. *C. A.* **22,** 985.—Ergotamine administered prior to the injection of killed paratyphoid B bacilli inhibits or prevents the appearance of specific agglutinins in the circulation. G. H. S.

Chemical findings in the blood of the dog after temporary obstruction of the pylorus. RUSSELL L. HADEN AND THOMAS G. ORR. Univ. of Kansas. *J. Exptl. Med.* **48,** 591–601(1928); cf. *C. A.* **21,** 3391, 3392; **22,** 116.—The toxemia characteristic of upper gastrointestinal tract obstruction may be produced by temporary obstruction of the pylorus. This procedure affords an opportunity for studying the toxemia in the absence of mech. factors, operative risk and infection. Animals which spontaneously recover from the toxemia may show a return of the blood chloride to normal when only distd. H_2O is given In such instances there must be a redistribution of the body store of chlorides. The administration of NaCl by mouth to animals which show a toxemia without evidence of spontaneous recovery causes a rapid return of the blood to normal.

There is a marked diuresis with high N excretion during the toxemia. This is evidently due to the increased protein destruction, which, however, ceases on the return of the blood chlorides to normal. C. J. WEST

Cause of the delay in the van den Bergh reaction in icteric serum. NORIBUMI SOFUE. Imperial Inst. Tokyo. *Proc. Imp. Acad. (Japan)* **4**, 27-9(1928).—Stromata of hemolyzed blood corpuscles cause a delay in the van den Bergh reaction, whether these stromata are previously injected into the animal from which serum is obtained or whether they are added *in vitro* to the serum. The stromata react with bilirubin *in vitro*, oxidizing the latter and producing colors analogous to those obtained in Gmelin's test. The biphasic and delayed reactions appear to depend on this phenomenon. C. J. WEST

Pancreatic activity in diabetes mellitus. SEIZABURO OKADA, TSUNAMOTO IMAZU, KWANICHI KURAMOCHI, KATSUO HORIUCHI AND TOSHIO TSUKAHARA. Tokyo Imp. Univ. *Proc. Imp. Acad. (Japan)* **4**, 134-5(1928).—The disturbance of pancreatic function manifests itself in the decrease of enzymic activity, or of the amt. of juice, or of both, the greatest alteration in enzymic efficiency and activity being in the proteolytic and lipolytic enzymes. There may be disturbances either in the internal or of the external secretion of the pancreas, or of both, the severity of the diabetes not necessarily running parallel to the degree of disturbance in the external secretion. C. J. WEST

Influence of fat-deficient diet on the growth of transplanted tumors. WARO NAKAHARA AND EIICHI SOMEKAWA. Inst. Phys. Chem. Research, Tokyo. *Proc. Imp. Acad. (Japan)* **4**, 236-9(1928).—The almost total absence of fats and lipoids in the diet does not perceptibly affect the growth in albino rats of transplanted tumors, both sarcoma and carcinoma. C. J. WEST

Increase in blood sugar in experimental sun-stroke of the rabbit. TSUNAMOTO IMAZU. Tokyo Imp. Univ. *Proc. Imp. Acad. (Japan)* **4**, 252-3(1928).—The blood of rabbits killed by exposure to the sun had a definitely higher sugar content than before exposure. Those rabbits which survived showed no hyperglycemia. C. J. WEST

Pancreatic secretion in disturbed secretion. SEIZABURO OKADA, TSUNAMOTO IMAZU, KWANICHI KURAMOCHI, MASAKA MATSUBARA AND TOSHIO TSUKAHARA. Tokyo Imp. Univ. *Proc. Imp. Acad (Japan)* **4**, 423-4(1928).—The pancreatic secretion is not necessarily disturbed by disturbed gastric secretion; it may be increased in some cases. Thus it is evident that the presence of HCl is not necessary in order to stimulate normal pancreatic secretory activity. C. J. WEST

Cytochrome in tumor tissues. HIDETAKE YAOI, HIROSHI TAMIYA AND WARO NAKAHARA. Tokyo Imp. Univ. *Proc. Imp. Acad. (Japan)* **4**, 433-5(1928).—Fujinawa rat sarcoma contains a large amt of cytochrome, an intracellar respiratory pigment. Flexner-Jobling rat carcinoma and Bashford mouse carcinoma contain a medium amt. and Rous chicken sarcoma either small or no demonstrable quantity. It is probable that these facts can be correlated with the difference in the ability of different types of tumors to withstand the deprivation of O. C. J. WEST

I content of milk powder (MATHIESON) **12.**

LABBÉ, MARCEL, AND NEPVEUX, FLORIDE: **Acidose et Alcalose. Physiologie. Pathologie. Thérapeutique.** Paris: Masson & Cie. 296 pp. F. 30.

H—PHARMACOLOGY

A. N. RICHARDS

Lipoid nephrosis in adrenalectomized rats and guinea pigs. F. D. GUNN, C. F. CORI AND F. A. HARTMAN. Univ. of Buffalo. *Proc. Soc. Exptl. Biol. Med.* **25**, 410-1 (1928).—There was a definite increase in the kidney lipoid of guinea pigs and rats after the removal of both adrenals. This increase was not so marked as that present in adrenalectomized cats. C. V. B.

Effect of thyroxine on growth rate and carbon dioxide production of chick embryo. ERNEST B. HANAN. Univ. of Buffalo. *Proc. Soc. Exptl. Biol. Med.* **25**, 422-5(1928).—When $^1/_{40,000}$ mg. of thyroxine is introduced into the air sac of the hen's egg at the 8th day of incubation there is a distinct increase in CO_2 production extending over a period of about 3 days. This is followed by a period of marked depression below normal, lasting 8 days. Doses as small as $^1/_{200,000}$ mg. produce no demonstrable effect on viability or metabolism. Larger doses ($^1/_{30,000}$ mg. or more) of thyroxine are generally fatal when injected into the air sac at the 6th or 8th day of incubation. A considerably larger amt. ($^1/_{600}$ mg.) is tolerated when dild. (possibly modified) by injection or absorp-

tion into the albumin at an earlier stage of development, but the period of incubation is not appreciably modified and the wt. accretion curve is not altered. C. V. B.

Some experiments on the etiology of diabetes mellitus. E. W. Schultz, S. J. Johnson and G. T. Akamatsu. Stanford Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 432–4(1928).—The authors were unable to confirm the observations by Bergey, who claimed that he had been able to produce diabetes mellitus in rabbits by a single intravenous injection of a Berkefeld filtrate of the urine of diabetic patients. C. V. B.

Studies on quinine and quinidine. V. Do they have a specific action on autonomic nerve ends? Erwin E. Nelson. Univ. of Michigan. *Proc. Soc. Exptl. Biol. Med.* **25**, 499–501(1928); cf. *C. A.* **22**, 2207–8.—Quinine and quinidine, though apparently having a selective action on the motor sympathetics to the blood vessels in cats and dogs, do not have such an action for all the motor fibers of the sympathetic division. C. V. B.

Significance of reticulocyte as index of regeneration in different types of experimental anemia. Richard Johnson and Hilding Berglund. Univ. Hospital, Minneapolis. *Proc. Soc. Exptl. Biol. Med.* **25**, 517–21(1928).—In phenylhydrazine anemia there was an exceedingly rapid regeneration of erythrocytes with as high as 41.3% of reticulocytes; the curve of reticulocytes ran parallel with the normoblast curve. In anemia in a dog injected intravenously with distd. H_2O, the response of the reticulocytes, erythrocytes and leucocytes was less intense than in the phenylhydrazine anemia. In anemia produced by repeated bleeding of a dog, the leucocytes were little affected; the response of the reticulocytes and normoblasts was less lively than in the other 2 anemias. Three factors appear of importance in estg. the regenerative value of a given reticulocyte count. Neither the percentage of reticulocytes, nor their total no. per unit vol. is sufficient for interpretation. The level of the erythrocyte count and its direction, *i. e.*, whether decreasing or increasing must be studied also. C. V. B.

Positive effect of tyrosine feeding upon excretion of the reducing urinary compound in myasthenia gravis. Hilding Berglund and Anne Lohmann. University Hospital, Minneapolis. *Proc. Soc. Exptl. Biol. Med.* **25**, 521–3(1928).—The feeding of a cyclic amino acid like tyrosine increases the amt. excreted of the reducing urinary compd. described in a case of myasthenia gravis. C. V. B.

Effects of in vivo prepared toxic products of B. coli upon the guinea pig. W. H. Harris and O. M. Larimore. Tulane Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 528–9 (1928).—Cultures of *B. coli communior* were injected into the peritoneal cavity of guinea pigs. The exudate from the resultant peritonitis, dild. and filtered through a Berkfeld filter, was injected subcutaneously into a series of guinea pigs. The resulting symptoms were not like those previously noted when the typhoid bacillus had been employed in a similar manner. C. V. B.

Antipyretic action of magnesium chloride alone and combined with amidopyrine. H. G. Barbour and J. E. Winter. Univ. of Louisville. *Proc. Soc. Exptl. Biol. Med.* **25**, 582–7(1928).—$MgCl_2$ was effectively antipyretic in hay-infusion fever of rabbits in doses of 200 mg. per kg. and upward. By combining $MgCl_2$ and amidopyrine in doses which separately are ineffective, marked antipyresis was produced in such rabbits. Antipyretic synergism was demonstrated by combining effective doses of these drugs. The combined doses proved slightly less toxic to normal white mice than would be predicted by the known toxicity of the 2 component drugs. C. V. B.

Influence of magnesium salts upon the toxicity and antipyretic action of the salicylates. J. E. Winter and H. G. Barbour. Univ. of Louisville. *Proc. Soc. Exptl. Biol. Med.* **25**, 587–90(1928).—Mg salts in mice appear to reduce the toxicity of salicylates. Mg augments the antipyretic action of Na salicylate and of aspirin. When Mg salts are given subcutaneously with salicylate to fevered rabbits, the earlier stages of antipyresis are characterized by marked synergism. C. V. B.

Antagonism of nicotine action by cocaine. C. H. Thienes. University of Oregon. *Proc. Soc. Exptl. Biol. Med.* **25**, 591(1928).—Cocaine prevented nicotine from producing its usual effect of depression on smooth muscle. Cocaine failed to prevent depression of intestinal segments by atropine. Thus it appears that cocaine affects the ganglia, or at least some portion of the enteric nervous system, as well as the smooth muscle. C. V. B.

Some aspects of the pharmacology of apomorphine hydrochloride. J. E. Gorrell and P. L. Gray. Univ. of Chicago. *Proc. Soc. Exptl. Biol. Med.* **25**, 619–22(1928).—The development of a green color in old (1 week to 1 yr.) apomorphine-HCl solns. appears to be accompanied by no qual. or quant. changes in the pharmacol. actions of the drug. Dogs receiving an emetic dose of apomorphine daily for 4 months exhibit

no tolerance or hypersusceptibility, and no nauseant conditioned salivary reflex similar to that of morphine appears. C. V. B.

The development of isoagglutinins following transfusions. K. LANDSTEINER, PH. LEVINE AND M. L. JANES. Rockefeller Institute. *Proc. Soc. Exptl. Biol. Med.* **25**, 672–4(1928).—In 5 individuals transfused several times with the blood of the same donor of their own group, no abnormal agglutinins were observed. In a 6th individual of group 0, 2 transfusions were made with blood from the same donor. An abnormal isoagglutinin was found in the serum of the transfused individual that reacted on numerous bloods, and stronger on several others than on that of the donor. From tests it appeared that an agglutinin of very slight activity was present originally in the serum of the recipient and that the amt. of this agglutinin was increased as a result of the transfusion. In the serum of another transfused individual were found agglutinins which acted weakly. C. V. B.

Bronchial perfusion of isolated lung as a method for studying pharmacologic reactions of bronchiolar muscle. TORALD SOLLMANN AND W. F. VON OETTINGEN. Western Reserve Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 692–5(1928).—Description is given of a method permitting the study of the responses of the bronchial muscle to autonomic and muscular poisons, and giving a clearcut picture of their action, without the interference of changes of the circulation or of the vol of the heart. This method is based on measuring the rate of flow of a Locke soln. through the bronchial tree; the fluid is allowed to drain off by filtration. C. V. B.

Glycogen formation under amytal anesthesia. H. M HINES, C. E. LEESE AND A. P. BARER. State Univ. of Iowa. *Proc Soc. Exptl. Biol. Med.* **25**, 736–7(1928).—About the same increase in muscle glycogen occurred following glucose injection in animals with, as without, amytal anesthesia. The increase in liver glycogen was over twice as great in unanesthetized animals as in those under amytal anesthesia. Animals under this anesthetic are therefore thought to be unsuitable for study of problems on carbohydrate storage. C. V. B.

Effect of ash of liver on blood regeneration in pernicious anemia. C. A. ELDEN AND WM. S. MCCANN. Univ. of Rochester. *Proc. Soc. Exptl. Biol Med.* **25**, 746–8 (1928).—The administration of liver ash to 2 patients with typical pernicious anemia resulted in the appearance of some of the preliminary phenomena of a remission (increase in percentage of reticulocytes). In neither case did a true remission occur until Minot's liver ext. was given. The active substance in liver ash was lost or inactivated by dissolving the ash in HCl, neutralizing with NaOH, and evapg. the salts to dryness. C V. B.

Sensitivity of isolated intestine of athyroid, normal and thyroxinized rabbits to physostigmine and adrenaline. CHAPMAN REYNOLDS Tulane Univ. *Proc. Soc. Exptl. Biol. Med.* **25**, 771–3(1928).—Duodenal segments from normal, athyroid and thyroxinized rabbits showed no significant or const. difference in their response to adrenaline (20 expts.), perhaps because, owing to the instability of adrenaline in the alk. Tyrode soln , it was impossible to obtain simultaneous contact of the same concn. of adrenaline with the segments In 16 expts., 12 showed a greater sensitivity to physostigmine in thyroxinized than in athyroid segments, 2 showed less and 2 were apparently equal in response. In 5 expts. the response of the thyroxinized intestine was greater than that of the normal rabbit intestine in one it was apparently equal. C. V. B.

Liver extract (perneman) for treating pernicious anemia and the experience therewith in Holland. ERNST LAQUER AND A. P. W. MIJENCH. Pharmaco Therap.-Inst. Univ. Amsterdam. *Nederland Tijdschr. Geneeskunde* **72**, I, 1664 70(1928); cf. *C. A.* **22**, 3929.—Favorable reports are made in 14 cases of anemia. The writers have analyzed various liver exts., detg the total N content (7 to 8%), the urea content (2 to 3%), the amino N (2 to 3%), the lipoid content (0.3 to 0.5%), the S content (0.7 to 0.8%), the P content (0.6 to 1.0%), and the reducing power according to Hagedorn and Jensen. Vitamin A was found to be absent. R. BEUTNER

Chlorine gas poisoning and the process of becoming accustomed to chlorine. G. LUTZ. *Zentr. Gewerbehyg. Unfallverhüt.* **14**, 175–6; *Chem. Zentr.* **1927**, II, 716–7.—At first breathing Cl gas has the ordinary well-known irritant effects, which are rendered essentially less pronounced by the use of coffee. Following this stage, there is apparent a tendency to become accustomed to the gas with cessation of coughing, but without diminution of other injurious effects, such as vasomoter (albuminuria) effects. Caffeine is to be used in combating these effects. C. C. DAVIS

The mechanism of hydrogen sulfide poisoning (cineomatographic representation). G. RODENACKER. *Zentr. Gewerbehyg. Unfallverhüt.* **14**, 176–8; *Chem. Zentr.* **1927**, II, 717.—The catalytic active Fe in the blood is converted into FeS by H_2S, as a result of

which there is cessation of oxidation processes, internal suffocation and increased O content of the venous blood. With 0.5% H_2S, "Elektroferrol" with 0.1% $FeCl_3$ had an intracardial healing effect in guinea pigs and rabbits. These 2 substances also had a beneficial effect in human subjects with H_2S-conjunctivitis. Given orally their influence is still appreciable but less pronounced. Animals exposed to 0.1% H_2S could not be saved by this treatment. C. C. DAVIS

The present status of experimental and clinical research on the cause of lead poisoning. PAUL SCHMIDT. Univ. of Halle. *Zentr. Gewerbehyg. Unfallverhüt.* **14**, 180–2; *Chem. Zentr.* **1927**, II, 717.—A *micromethod for the detection of Pb in exts. and organs of the body* is suggested. The Pb compd. is converted into PbO_2 and this is identified by the blue color imparted by the Arnold-Menzel-Trillat reagent. Tests of the value of the method were carried out on so-called "healthy lead carriers," who were free from symptoms of colic and paresis and with normal conditions of eyes and nerves. With these subjects, considerable quantities of Pb were found in the urine and in the blood stream. C. C. DAVIS

The condition of the blood from the qualitative point of view in carbon monoxide, lysol and aniline oil poisoning. ARNETH AND ALBACHT. *Zentr. Gewerbehyg. Unfallverhut* **14**, 225–8; *Chem. Zentr.* **1927**, II, 1732.—A discussion (cf. Arneth, *Qualitative Blutlehre* **IV**, Munster; cf. *C. A.* **15**, 2119). C. C. DAVIS

The influence of insulin on the action of ephedrine on the blood pressure of human beings. K. CSÉPAI AND S. V. PINTER-KOVÁTS. Univ. of Pest. *Munch. med. Wochschr.* **74**, 1011; *Chem. Zentr.* **1927**, II, 709.—The cardiovascular antagonism which has been observed between adrenaline and insulin does not occur between ephedrine and insulin. The effect of ephedrine on the blood pressure is not influenced by insulin. C. C. DAVIS

Action of light and cobra venom. MUCH, PEEMÖLLER AND HAIM. Univ. Hamburg. *Munch. med. Wochschr.* **74**, 1365–6; *Chem. Zentr.* **1927**, II, 1733.—Expts. showed that the action of cobra venom on red blood corpuscles is completely destroyed by irradiation with ultra-violet light. Cobra venom dild. 1:2000 was irradiated in quartz glass flasks with 72-fold erythematic doses from a Hg lamp 0.5 m. distant. While at a diln. of 1:5000 the non-irradiated venom in quantities of 1.0–0.25 dissolved completely 0.5 cc. of a 10% emulsion of human erythrocytes after 2 hrs. in an incubator; a corresponding sample with irradiated cobra venom showed no hemolysis even after 20 hrs. in the incubator. The toxicity of the venom toward white mice was destroyed or greatly reduced by irradiation. It may therefore be possible, instead of relying upon uncertain serum therapy, to carry out *prophylaxis with venom which has been attenuated by irradiation*, or to combine such an attenuated poison with irradiated or non-irradiated lipoid. C. C. DAVIS

Experimental investigations on tetramethylammonium oxalate ("Albiogen"). ADRIANO VALENTI. Univ. Milan. *Arch. farmacol. sper.* **45**, 49–66(1928).—The toxic doses of $(CO_2NMe_4)_2$ for frog, guinea pig, rabbit and dog are 0.0026, 0.008, 0.006 and 0.008 g., resp., per kg. Combination with $(CO_2H)_2$ does not alter the characteristic pharmacological properties of the quaternary NH_4 base. The toxic dose causes paralysis of the motor centers, while moderate doses (0.005 g per kg.) result in a marked increase in blood pressure and retardation of heart beat—phenomena due to a peripheral action similar to muscarine on the myocardium and the vascular walls. Renal secretion is activated, but this is again restored to normal by administration of atropine. The effects are quite prolonged but no secondary paralytic phase develops, the functions returning to normal as the drug is eliminated. On account of the oxalic acid present the therapeutic use of the drug by intravenous injection is inadvisable. A. W. D.

Action of selenium, tellurium and cobalt on carbohydrate metabolism. F. PELLEGRINO AND G. GAIZZONE. *Arch farmacol. sper.* **45**, 75–80(1928).—Intramuscular injection of H_2SeO_4 and H_2TeO_4 into rabbits resulted in all cases in an increase in blood sugar. This increase is attributable in only small measure to the acid reaction of the injected soln., since HCl of the same p_H gives only a slight and transient hyperglucemia. If the H_2SeO_4 or H_2TeO_4 is injected one hr. after an intramuscular injection of glucose (1 g. per kg.) there is also a slight but const. increase in blood sugar. However, these acids do not have the power of neutralizing the hypoglucemic effect of a $^2/_3$ rabbit unit of insulin. Intramuscular injection of $Co(NO_3)_2$ (1 cc. of 0.05 *N* soln. per kg.) produces a marked hyperglucemia in the fasting rabbit. When injected simultaneously with $^2/_3$ unit of insulin the hypoglucemic action of the latter is only partially neutralized. A. W. DOX

Influence of caffeine on the survival of the red corpuscles outside the organism. G. B. ZANDA. Univ. Cagliari. *Arch. farmacol. sper.* **45**, 81–91(1928); cf. *C. A.* **22**,

2985.—Addn. of caffeine to defibrinated blood retards the disintegration of the red cells. This effect is proportional to the amt. of caffeine used. With 1% caffeine the cells retain their structure about 4 times as long as in the controls. The comparisons were made by noting the vol. of sediment obtained on centrifuging the sample. A. W. Dox

Chemotherapy of malignant tumors. Cassio Starnotti. *Arch. farmacol. sper.* **45**, 113–52(1928).—Twenty-one cancer patients were given daily injections of colloidal prepns. for a period of 1 month; 6 received colloidal S, 5 colloidal Pb, 5 colloidal Cu and 5 colloidal Se. Blood counts and urine tests were made at the beginning and end of the treatment. The greatest improvement was noted with the S treatment. The erythrocyte count showed an increase and the general nutrition improved. All of the prepns. increased the leucocyte count, and diminished the pain and secretion. The action of these prepns. is not considered specific. A. W. Dox

Synergized morphine. Paramorphine. Vittorio Susanna. Univ. Naples. *Arch. farmacol. sper.* **45**, 193–9(1928).—"Paramorphine," a synergized morphine prepn. used in treatment of morphinism and claimed to have all the therapeutic applications of morphine itself, was subjected to animal tests in comparison with morphine. The synergizing constituents do not alter the morphine action on the isolated mammalian heart, the frog heart or the blood pressure Expts. on narcosis and respiration, however, show a potentiation of the morphine effect. The same dose gives a longer and more profound narcosis as compared to morphine, and the respiratory center becomes more depressed. With dogs and rabbits receiving daily doses, habituation does not develop and an increased dosage is not required to give the initial effects. When the administration of "paramorphine" is discontinued the general effects disappear and the animals return to normal. Synergism is shown also by the increased toxicity of "paramorphine" as compared to morphine. A. W. Dox

Clinical observations on the use of synergized morphine and heroine. Pericle Pozzilli. Univ. Rome. *Arch. farmacol. sper.* **45**, 200–8(1928).—Cases of arteriosclerosis, pulmonitis and morphinism are reported where treatment with "paramorphine" (morphine synergized with *l*-hyoscyamine) was used to advantage. A. W. Dox

The use of acoin in clinical practice. Guanidine therapy of diabetes mellitus. L. Cannavò. Univ. Messina. *Arch. farmacol. sper.* **45**, 218–40(1928); cf. *C. A.* **22**, 1397.—Acoin, $EtOC_6H_4N{:}C(NHC_6H_4OMe)_2.HCl$, is recommended in the treatment of human diabetes because of its insulin-like action and its low toxicity as compared to other guanidine derivs. In mild cases it may replace insulin wholly or in part. Daily administration of a few cg of acoin increases the patient's tolerance of carbohydrates and permits return to a practically normal diet. It diminishes blood sugar, supresses glucosuria and acidosis and leads to increase in body wt. A. W. Dox

Blood regeneration. J. Pal. Allgem Krankenhauses in Wien. *Wiener klin. Wochschr.* **41**, 1216–7(1928).—Daily oral administration of 10 mg. of histamine resulted in blood regeneration in primary and in secondary anemia. A prepn. of suprarenal cortex administered orally in 15 cases of secondary anemia gave 13 positive results. In 2 cases of pernicious anemia there was 1 positive result. D. B. Dill

Pharmacology of chlorophyll. T Gordonoff. Univ. Bern. *Z. ges. exptl. Med.* **54**, 294–312(1927).—Chlorophyll increases the contractility of the isolated frog heart in concns. of 1:20,000, the action being on the heart muscle. There is a similar action on intestine and muscle. The blood pressure increases somewhat and there is a slight diuresis. The minute vol. and the rate of respiration are somewhat decreased. Chlorophyll is retained in the spleen and liver and the hemopoesis is increased. Hemin has a similar but less marked action. Bibliography. F. L. Dunn

Changes in permeability following insulin injection. Wm. F. Peterson and Ernst. F. Müller. Univ. of Ill. *Z. ges. exptl. Med.* **54**, 415–38(1927).—The sugar, protein, cell and Ca content of lymph and blood were compared in dogs following insulin injections. An increased permeability similar to that observed with peptone and protein was observed. Bibliography. F. L. Dunn

Biochemistry of Bayer 205. W. A. Collier. Inst. argentinischen Landwirtschaftsministeriums. *Z. ges. exptl. Med.* **54**, 606–12(1927); cf. *C. A.* **21**, 964.—Sb derivs. have no effect *in vitro* on the Bayer 205-globulin combination, but appear to increase the rate of breakdown of this combination, *in vivo* suggesting the explanation for the value of alternating Bayer 205 and Sb compds. in therapeutics. F. L. Dunn

The action of pancreas extracts and insulin upon the blood sugar. J. Th. Kuznetzov. Wissenschaftlichen Inst. Leshaft in Leningrad. *Z. ges. exptl. Med.* **55**, 248–65(1927).—The alc. ext. was made from the pancreas of cats following essentially the method of Cohnheim and Hall (*Hoppe-Seylers Z. physiol. Chem.* **42**(1904); **47**

(1906); *Am. J. Physiol.* **18** (1907)). The ext. showed glucolysis in diabetic blood *in vitro;* the dialyzate and ash did not. Insulin did not show glucolysis *in vitro.* Heating the ext. in NaOH for a half hr. or heating to 120° for 20 min. did not destroy its glucolytic action. The ext. was effective when given by mouth. Conclusion: The discrepancy in properties between the ext. and insulin suggests that the pancreas contains another hormone which is of importance in carbohydrate metabolism. Bibliography. F. L. DUNN

Remarks on the work of L. Asher, "Studies of coramine and cardiazole." F. HILDEBRANDT. Med. Akad. Düsseldorf. *Z. ges. exptl. Med.* **55,** 284–6(1927); cf. *C. A.* **27,** 3960.—H. finds the convulsive dose for cardiazole to be 10–15 mg. per kg. in rabbits in contrast to Asher, who found it to be 5–10 mg. per kg. The dose of cardiazole is one-fifth of that of coramine. F. L. DUNN

The role of the reticulo-endothelial system in streptococcus infections. IV. Therapeutic studies with proteins, carbohydrate, vitamin and mineral salts. N. LOUROS AND H. E. SCHEYER. Staatl. Frauenklinik Dresden. *Z. ges. exptl. Med.* **55,** 702–23 (1927); cf. *C. A.* **22,** 2781.—Aolan, caseosan, novoprotin and lipatren were effective in protecting white mice against lethal streptococcus infections in daily doses of 0.1–0.2 cc. The value of atropine, adrenaline, pilocarpine, phystostigmine, lobeline, pituigan and klavipurin, in protecting mice suggested to L. and S. that the vasomotor neural system is of parallel importance to the reticulo-endothelial system in protecting the mice. Protein-free dialyzates of spleen, liver and carcinoma tissue were also protective. Carbohydrate solns. showed no effect, and mineral salt complexes only a slight effect. V. Therapeutic studies with carbon. *Ibid* 724–9.—Colloidal C protects by increasing phagocytosis, the bacteria being adsorbed by the C. The acid formation of the bacteria increased the activity of the C. Bibliography. F. L. DUNN

The effect of synthetic cycloethylamines upon the action of adrenaline and histamine on the autonomic end organs. VI. Results with cyclic side chain ethylamines. S. LOEWE. Univ. Tartu-Dorpat. *Z. ges. exptl. Med.* **56,** 271–333(1927).—The actions of 66 members of this group were studied pharmacologically in cats, dogs, rabbits and rats; 33 substances had not been studied pharmacologically before. F. L. DUNN

The action of veratrine. H. RHODE. *Z. ges. exptl. Med.* **56,** 398–401(1927).—R. studied the relationship between p_H and concn. of veratrine, cocaine, stovaine, novocaine and quinine, lethal for paramecia. Veratrine in combination with a local anesthetic increased the toxicity of the former. Calcium reduced the toxicity of veratrine. R. suggests that these changes are due to swelling and shrinking of the cell wall which affects the penetration of the veratrine. F. L. DUNN

The theory of action of poisons. Relationship between concentration and toxicity. WILHELM R. GLASER. Univ. Würzburg. *Z. ges. exptl. Med.* **56,** 410–32(1927).—An exptl. and math. study of the action of HCN and AsH_3 showing that the data satisfy the relation, $(C - b)[1 - e^{-a(t - g)}]$, in which C is the concn., b is a quant. poisoning factor, a is a proportionality factor related to diffusion, t is time and g a poisoning factor related to the time. F. L. DUNN

The pharmacologic action of an antipyrine derivative, antipyriliminopyrine. WERNER LIPSCHITZ AND JOSEF OSTERROTH. Univ. Frankfort. *Z. ges. exptl. Med.* **56,** 433–53(1927).—The chloride was used. In warm-blooded animals the effect on the medulla oblongata was most prominent. There was some depression of the respiratory center and the antipyretic effect was less than that with antipyrine and pyramidone. There was no effect on the heart. The drug was rapidly excreted. In frogs there was a curare action. In mammals the soporific effect was greater than for pyramidone. The lethal dose was: rabbits, 0.15–18; white mice, 0.3–0 4; dogs, 0.3; and frogs, 0.7 g. per kg. F. L. DUNN

The pharmacology of iron and aluminum in relation to therapeutic uses. H. A. MCGUIGAN. *J. Lab. and Clin. Med.* **12,** 790–4(1927); *Physiol. Abstracts* **12,** 584.—The absorption of Al is so slight that toxic effects are unusual when taken by the mouth; given hypodermically it becomes of toxic importance. The hypodermic administration of Fe is inadvisable as toxic actions almost invariably follow. H. G.

Permeability relationships in secretion of intraocular fluid. A. GAEDERTZ AND A. WITTGENSTEIN. *Klin. Wochschr.* **7,** 63–5(1928); *Physiol. Abstracts* **13,** 76.—Various substances were injected intravenously in dogs and their appearance in the intraocular fluid was followed. Diffusible anions are secreted into the eye; in this group were acid dyes, salicylic acid, thiocyanic acid, ferrocyanic acid, chloride, bromide and iodide. Cations were indiffusible, the substances tested being 8 basic dyes, 3 alkaloids, Ca, K and Na. Colloidal acid dyes also did not appear in the intraocular fluid. H G.

Poisoning by hydrogen sulfide. V. RODMAKER. *Zentr. Gewerbehyg. Unfallverhüt.* **14,**

205-7(1927); *Bull. Hyg.* **3**, 587(1928).—In a concn. of 1.5 vol. per 1000 the organism loses power to utilize O_2. The ganglion cell being very sensitive determines the clinical picture of H_2S poisoning. The destruction of these cells in the olfactory region prevents the perception of larger amounts. Doses of 0.15 vol. per 1000 show erythema, conjunctivitis or swelling of the eyelids and lacrimation. R. explains why the H_2S produced in the body has no ill effects. GEORGE F. GREENBANK

The occurrence of caffeine in human milk after the ingestion of coffee. E. SCHILF AND R. WOHINZ. Univ. Berlin. *Klin. Wochschr.* **7**, 1186(1928).—See *C. A.* **22**, 3698. MILTON HANKE

The pharmacology and physiology of iron. E. STARKENSTEIN AND H. WEDEN. *Klin. Wochschr.* **7**, 1220-5(1928); cf. *C. A.* **21**, 1494.—Ferric iron prepns. that are introduced into the body by any route are always inactive. This form of Fe is removed from the circulation by, and stored in, the spleen, and *only* in the spleen. The liver reduces this inactive ferric Fe to inactive ferrous Fe; the latter is then used for the synthesis of hemoglobin. Active ferrous Fe, as found in $FeCl_3$, is oxidized to the ferric condition by the body tissues. The ferric compd. so produced is quite different from any ferric compd. that is ordinarily introduced into the body; for it remains in the circulation for a long time and remains in the filtrate from deproteinated blood. The spleen does not remove this form of Fe from the blood and the liver can attack it only after it has been reduced to inactive Fe by the tissues. The therapeutic value of an Fe prepn. cannot be judged by the Fe depots in the spleen and liver. On the contrary, Fe that appears in these 2 organs is inactive and useless. MILTON HANKE

The influence of small quantities of water on vascular tonus. E. FLATOW AND M. MORIMOTO. *Klin. Wochschr.* **7**, 1265-6(1928); cf. following abstract.—The injection of 1 cc. of water into the femoral artery of dogs leads to a dilatation of the blood vessels of the leg. A hypertonic salt soln. leads to a constriction which is then followed by a dilation of the blood vessels. The cat is much less reactive. Water produces a slight dilatation in most cats; but it may, occasionally, produce a constriction. A constriction of the blood vessels is usually obtained, in rabbits, after injecting water. MILTON HANKE

Effect of small doses of adrenaline, of water, of hypotonic salt solution and of blood in causing vasodilatation in dogs. E. FLATOW AND M. MORIMOTO. Univ. Berlin. *Arch. exptl. Path. Pharmakol.* **131**, 152-8(1928); cf. preceding abstract.—Perfusion of the extremity with solns. contg. small amts. of adrenaline, with distd. water or with hypotonic NaCl solns. causes vasodilatation. Hypertonic solns. of NaCl cause a slight vasoconstriction with a subsequent dilatation. Freshly withdrawn hirudinized blood is inert but after a short exposure to the air it causes vasodilatation. G. H. S.

The mechanism of the action of synthalin. H. STAUB AND O. KÜNG. *Klin. Wochschr.* **7**, 1365-6(1928).—Synthalin is a protoplasmic poison. Its administration leads to a decreased respiration of the body tissue and an increased production of lactic acid at the expense of glycogen and glucose. Synthalin in 0.05% concn. inhibits the growth of bacteria. MILTON HANKE

Colloidal silver. **Its use for diagnostic and therapeutic purposes.** J. VOIGT. *Klin. Wochschr.* **7**, 1417-9(1928).—Solns. of any of the patented colloidal Ag prepns. contain appreciable concns. of Ag ion. As these solns. are dild., the no. of Ag ions increases. This phenomenon appears to be a property of the colloidal Ag and is independent of the protective colloid that is used to stabilize the Ag prepn. The Ag ions disappear when an unprotected colloidal Ag prepn. is mixed with serum. An examn. of serum with the ultra-microscope fails to reveal any individual particles. The colloidal Ag prepns. contain well defined particles that appear blue to blue-green in color. An enormous increase in the no. of particles is observed when the colloidal Ag prepn. is mixed with serum. The new particles are yellow in color which indicates that they consist of serum aggregates to which a large no. of very fine Ag particles have been adsorbed. The no. of the yellow particles is roughly proportional to the concn. of the serum. This may develop into a method for *estg. the number of colloidal mols. in a protein soln.* MILTON HANKE

Effect of metallic salts on the glucolysis and respiration of tissues. MAURICE JOWETT AND JOHN BROOKS. Univ. Liverpool. *Biochem. J.* **22**, 720-38(1928).—The toxicity to glucolysis is in the order HgI_2, $HgCl_2 > Cu > Zn > Cl > Ca$. At low concentrations Pb^{++} slightly accelerates glycolysis of malignant tissues and accelerates their respiration if at much higher concns. Glucolysis appears to be more sensitive than respiration to heavy metals in the case of malignant tissue. For normal tissues the converse is true. B. HARROW

Conclusions from extended experiments with nitrous oxide, acetylene, ethylene-

oxygen anesthesia. JULIUS D. GOLDMAN. *Dental Cosmos* **70**, 920–3(1928); cf. *C. A.* **21**, 274.—From numerous expts. on animals (albino rats, albino mice, cats, rabbits, guinea pigs, dogs), and extensive clinical experience with human subjects, a series of 27 conclusions is drawn concerning the use of gas mixts. for the production and maintenance of anesthesia. Thus, anesthesia did not occur until the % O_2 was less than 7 in N_2O-O_2 mixts., and less than 12 in C_2H_4-O_2 mixts., but occurred, as a rule but not invariably, when the O_2 content was 20 to 30% in C_2H_2-O_2 mixts. Symptoms of cyanosis did not appear when use was made of mixts. contg. C_2H_2-N_2O-O_2 and C_2H_2-C_2H_4-O_2. However, C_2H_2 tended to produce salivation. JOSEPH S. HEPBURN

Antiseptic compounds: some further derivatives of anilquinoline. C. H. BROWNING, J. B. COHEN, S. ELLINGSWORTH AND E. GULBRANSEN. *Proc. Roy. Soc.* (London) **B103**, 404–11(1928).—When the *quinoline nucleus* is modified, either by conversion into urethan derivs., or by condensation of the quinaldylurethans with nitroso compds., the resulting compds. are exceedingly active as bactericides. The phenyluramino compd. has only slight bactericidal properties. The acetylamino-β-naphthoquinoline compd. has a fairly powerful action on *Staphylococcus aureus* but only a comparatively slight action on *Bacillus coli*, while the unsubstituted β-naphthoquinoline compd. is very active. When the *benzene nucleus* is modified by addn. of further aromatic nuclei, the bactericidal power is not increased. However, addn. of cyclohexyl groups increases the activity. JOSEPH S. HEPBURN

Experiments and observations on the contact of animal tissue with bi-iodide of mercury dissolved in aqueous potassium iodide. H. CANDY AND W. BULLOCH. *Brit. J. Exptl. Path.* **9**, 179–81(1928).—HgI_2 is not appreciably sol. in H_2O, but is readily sol. in aq. solns. of KI. Such solns. do not have the corrosive action on instruments or tissues that characterizes the aq. solns. of $HgCl_2$, and they have been very extensively employed as disinfectants in the belief that they would possess a similar germicidal action. Expts on the disinfecting action of HgI_2 on catgut in the different stages of its manuf. show that HgI_2 cannot be regarded as a disinfectant of marked power whether dissolved in aq. solns. of KI or in EtOH or MeOH. Throughout the process the mol. unity of HgI_2 remains unimpaired. When attached to the tissue HgI_2 is attached as a unit still retaining its independent property of soly. in aq. KI solns. by which it can again become detached. The expts. incidentally suggest that the HgI_2 mol. has a greater degree of stability than has hitherto been suspected. HARRIET F. HOLMES

Insulin and the stomach. ERNST WIECHMANN AND WILHELM GATZWEILER. *Deut. Arch. klin. Med.* **157**, 208–15(1927).—X-ray examn. following a test meal showed that the subcutaneous injection of 40–50 units of insulin reduced by about 90 min. the time required for a healthy stomach to become empty. Peristalsis was strengthened in all cases. The stomach contents were removed in 10-cc. portions after the drinking of 300 cc. 5% alcohol colored with methylene blue. It was found by titration that the acidity of the stomach contents was not affected in a regular manner by the previous injection of insulin. In some cases the acidity was increased; and in those cases where the acidity was lowered it is probable that alk. duodenal juice had mixed with the stomach contents. P. Y. JACKSON

The pathogenesis of the toxic action of gaseous chlorine. I. L. KRICHEVSKII AND K. A. FRIEDE. *Krankheitsforsch.* **4**, 213–28(1927).—Histological studies show that gaseous Cl, *in vivo* as well as *in vitro*, brings about a disturbance of the degree of dispersion of the colloids of the blood and of the cells. Photomicrographs are given to show affected areas in the lungs, heart, liver, kidney, brain and marrow of rabbits exposed to Cl gas in such concns. that death occurred in a few minutes. P. Y. J.

α-Lobeline as a respiratory stimulant. WM. R. MARSHALL. McGill University Clinic, Montreal. *Arch. Internal Med.* **42**, 180–8(1928); cf. *C. A.* **21**, 2937 and CAMP, *J. Pharmacol* **31**, 392(1927).—α-Lobeline was given subcutaneously to 25 subjects (10 mg./150 lb.) and 2 dogs. In normal subjects the ventilation (I) increased by 12.81–68.3%, av. 31.25%, the vol. of each respiration (II) by 1.02–50.70, av. 14.98%. There is therefore actual stimulation with a max. 15 min and return to normal 30 min. after injection. The O_2 consumption (III) rose by 11.17%. The expired air showed in the 1st 5–10 min. an increase in CO_2 (washing out), followed by a decrease in CO_2 and increase in respiratory quotient (max. in 20 min.). The CO_2 content of arterial blood decreased 4.16% (by vol.) in human subjects, and 6.75% in dogs. The decrease of CO_2 persisted 1 hr. Under morphine and chloral hydrate I increased 12.5%, II 19.58%, III decreased 2.72%. Lobeline affects the vomiting center to the same extent; 12 persons became distinctly nauseated, 10 vomited persistently and severely. This and the drop of blood pressure observed by other authors are objectionable features in a drug. An intravenous injection caused temporary respiratory paralysis. MARY JACOBSEN

Toxicity of novasurol (merbaphen). Its action on the kidney of the rabbit. BENJAMIN J. JOHNSTONE AND H. M. KEITH. Dept. of Medicine, Henry Ford Hospital, Detroit. *Arch. Internal Med.* **42**, 189–216(1928).—Novasurol is somewhat less toxic than $HgCl_2$ (calcd. for the same Hg %). The toxicity increases with the dose/kg. The susceptibility of rabbits varies. Repeated doses equiv. to the therapeutic dose (3 cc./70 kg.) were toxic in certain animals. Tolerance for large doses over a long period of time may be established by allowing several weeks to lapse between the initial and the following doses. The kidney lesions resemble those produced by other Hg compds. Conclusions: The dose for a man of 70 kg. should not exceed 2 cc. The individual sensitiveness ought to be tested by a 0.5-cc. injection. MARY JACOBSEN

The effects of morphine and ether on the function of the kidneys. R. L. STEHLE AND WESLEY BOURNE. Dept. of Pharmacology, Faculty of Medicine, McGill University Clinic, Montreal. *Arch. Internal Med.* **42**, 248–55(1928); cf. *C. A.* **16**, 3700; **18**, 1141, 2381; **20**, 1115.—In dogs with bladder fistulas ether anesthesia causes anuria or oliguria and considerably reduces the *urea* concn (max. 4-5%). An initially high *Cl* content is also lowered, while an initially low one may be raised. The result is difficult to explain on the basis of the filtration-reabsorption theory and seems to point to a secretory mechanism. In morphine anesthesia the urine output is decidedly lowered while the urea and Cl excretion are hardly affected. Under combined ether-morphine anesthesia the excretion is considerably better than under ether alone This may be a salt diuresis but more likely less ether is needed to induce anesthesia in the presence of morphine and consequently there is less interference with the kidney function. MARY JACOBSEN

A case of solanine poisoning. ANTONIO ANGELETTI. *Giorn. farm chim* **76**, 309–14(1927).—Solanine was identified in the stomach contents of a chimpanzee 4 hrs. after death with the aid of the green $K_2Cr_2O_7$-H_2SO_4 color and the red color with Na_2SeO_4-H_2SO_4-alc. MARY JACOBSEN

Copper in medicine and industrial pathology. IV. Workers engaged in the mining and metallurgy of copper. VINCENZO MAZZI. *Rass. clin. terap. sci. affini* **27**, 192–212(1928).—In minute doses Cu compds. have a therapeutic effect. Large doses have a toxic effect (irritation of mucous membranes) with an indirect effect on the nerve centers. Ingested Cu causes violent vomiting and the elimination is also otherwise complete. A general systemic Cu poisoning in animals with unimpaired vomiting mechanism is unknown. Nor does chronic poisoning take place even with daily administration of doses too small to cause vomiting. Occupational Cu poisoning does not exist. The symptoms occasionally observed in workers must be attributed to impurities of the Cu ores or of the reagents used in the processes or to unsanitary general conditions. Large bibliography. Cf. *C. A.* **22**, 2788. MARY JACOBSEN

The treatment of pulmonary tuberculosis with sanocrysin. ATTILIO C. GRAPIOLO. *Rev. sud-americana endocrinol. inmunol. quimioterap.* **11**, 565–87(1928) (In Italian.)—Review and case histories. MARY JACOBSEN

Danger of narcotic drugs with neurosyphilis. FRED E. CLOW. *Am Med.* **34**, 253–4(1928).—A hypersusceptibility to morphine in neurosyphilis is reported. FRANCES KRASNOW

***p*-Phenylenediamine dermatitis.** H. H. HAZEN. *Am. Med.* **34**, 296–9(1928).—Twenty-five cases are reported due to hair dye and fur (rabbit, coney, leopard, squirrel, raccoon, Hudson Bay seal, sable). The cause is the use of p-$C_6H_4(NH_2)_2$ as a dye, which yields on incomplete oxidation quininediamine. This is very poisonous. F. K.

Carbolfuchsin paints in the treatment of certain cases of epidermophytosis. ALDO CASTELLANI. Tulane Univ. *Am. Med.* **34**, 351–2(1928).—Some success is reported. FRANCES KRASNOW

Dermatoses of anti-syphilitic treatment. H. WANSLEY BAYLY. *Am. Med.* **34**, 367–9(1928).—A case report which shows the intolerance of As, Hg and I and complete tolerance to Bi treatment. FRANCES KRASNOW

Untoward effect of narcotics and anesthetics upon robust and handicapped patients. JOHN L. YATES AND FORRESTER RAINE. Columbia Hospital, Milwaukee. *Ann. Surgery* **87**, 124–9(1928).—$CHCl_3$ causes a greater drop in O-carrying power than ether, ethylene or N_2O. The effect is slight in the normal but a drop of 15 to 25% in O-carrying power of anemic or heart-diseased individuals may mean a break in cardiac compensation. Opiates produce a slight alkalosis; N_2O and ethylene acidosis. There is less nausea with pantapon than with morphine. FRANCES KRASNOW

Colonic anesthesia in operations upon brain and spinal cord. CHARLES H. FRAZIER. Univ. of Penn. *Ann. Surgery* **87**, 161–71(1928).—In colonic anesthesia there is a method of inducing narcosis in which there is none of the sense of suffocation, no period of

excitement, no harmful influence upon pulse or blood pressure, no irritation of the upper air passages, a state of analgesia after consciousness has returned, a narcosis of uniform depth, the ether vapor is always warm, less nausea and vomiting and the amt. of ether in the system is a fixed known quantity. FRANCES KRASNOW

Effect of plasmochine on gamete destruction in malaria. W. MOLLOW. Univ. Sofia. *Arch. Schiffs-Tropen-Hyg.* **32**, 116–9(1928).—Plasmochine causes degeneration of the parasite. FRANCES KRASNOW

Cyanosis in plasmochine treatment. D. ORACHOWATZ. Univ. Sofia. *Arch. Schiffs-Tropen-Hyg.* **32**, 119–21(1928)—O_2-carrying capacity of the blood is lowered and cyanosis induced. FRANCES KRASNOW

Incidents in plasmochine treatment. WILHELM CORDES. *Arch. Schiffs-Tropen-Hyg.* **32**, 143–8(1928).—Plasmochine in daily doses of 0.1 g. is more toxic than quinine. FRANCES KRASNOW

Treatment of frambesia with bismogenol in northwestern "Hinterland" of Liberia. EDGAR MAASS. Mission Hospital Bolahun der Holy Cross Liberian Mission. *Arch. Schiffs-Tropen-Hyg.* **32**, 221–9(1928).—Good results were obtained with the drug. FRANCES KRASNOW

The therapy of black-water-fever. A G. TRABADOROS. Städt. Krankenhaus in Patras (Griechenland). *Arch. Schiffs-Tropen-Hyg.* **32**, 229–35(1928).—The combination of quinine and plasmochine is predicted as the medication of the future. F. K.

Yatren 105 in the prophylaxis and treatment of ordinary gastro-intestinal diseases in the tropics. H. KÜMMEL. *Arch. Schiff-Tropen-Hyg.* **32**, 256–61(1928).—Yatren 105 is recommended as a specific for intestinal diseases. FRANCES KRASNOW

A case of amebichepatitis cured with yatren. OTTO FISCHER. *Arch. Schiffs-Tropen-Hyg.* **32**, 326–7(1928). FRANCES KRASNOW

Yatren enemas as a rapid cure for bacillary dysentery. NORBERTO BACHMANN. *Arch Schiffs-Tropen-Hyg.* **32**, 327–8(1928).—Good results are reported. F. K.

Sodium chloride feeding in dropsy. A. VON KORÁNYI. *Arch. Verdauungs-Krankh.* **42**, 247–52(1928).—NaCl acts variously. It has a regulating effect on the osmotic exchange between the blood and the edemic fluid. The Na^+ increases the swelling of the tissue colloids. Of the several salts that may be used NaCl produces the smallest diuretic effect. FRANCES KRASNOW

The effect of rectal administration of alcohol on gastric secretion. HERMANN STEINITZ AND RUTH SCHERSCHEWSKY. Krankenhaus der judischen Gemeinde zu Berlin. *Arch. Verdauungsr-Kankh.* **42**, 520–30(1928).—A marked stimulation of the secretions was effected in practically all of 52 cases studied. Rectal injections of water, salt and sugar produced no marked effect. FRANCES KRASNOW

The action of alkaloid of "Chelidonium majus" on the gastro-intestinal canal. L. ALKAN. Berlin Univ. *Arch. Verdauungs-Krankh.* **43**, 46–52(1928).—Expts. made on tissues kept in Tyrode soln. show a reversible paralytic effect due to this alkaloid. When the tissue is treated at the same time with physostigmine, the effect of the latter is vitiated. Expts. *in vivo* show similar results The drug is not poisonous when administered subcutaneously in doses of 1.0 cg. per kg. body wt. (dog). This agrees with the findings of Probst and Hanzlik on rabbits. FRANCES KRASNOW

The mechanism of insulin action. JOHN C. HEMMETER. Woods Hole Lab. *Arch. Verdauungs-Krankh.* **43**, 182–96(1928).—Discussion and literature review. FRANCES KRASNOW

Tongue cancer and prophylactics such as radium treatment. PAUL LAZARUS. Marien Krankenhaus in Berlin. *Arch. Verdauungs-Krankh.* **43**, 283–99(1928).—Ra treatment is the method of choice. FRANCES KRASNOW

Dental anesthesia in the dog. E. R. FRANK. Kansas State Agr. College. *J. Am. Vet. Med. Assocn.* **73**, 232–4(1928).—Procaine is used to block the infraorbital nerve. FRANCES KRASNOW

Spinal analgesia. GREGORIO SINGIAN. *J. Philippine Islands Med. Assocn.* **8**, 45–9(1928).—Discussion with suggested changes in technic. FRANCES KRASNOW

Evaluation of the results of treatment of leprosy with the chaulmoogra derivatives. C. B. LARA. *J. Philippine Islands Med. Assocn.* **8**, 56–64, 263–72(1928).—589 negatives have been paroled or discharged from the Culion in the last 6 yrs. compared with only 47 cases for the previous 15 yrs. FRANCES KRASNOW

Yatren 105 in amebic dysentery. PEDRO T. LANTIN. Univ. of Philippines. *J. Philippine Islands Med. Assocn.* **8**, 78–81(1928).—Considerable therapeutic value was obtained in 26 cases. FRANCES KRASNOW

Results of antileprosy treatment of children in the Culion leper colony. CATALINO NICOLAS AND ELISA ROXAS-PINEDA. *J. Philippine Islands Med. Assocn.* **8**, 135–6,

314–7(1928).—Treatment of early or slightly advanced cases of leprosy in children with chaulmoogra prepns. (ethyl esters with 0.5% iodine) is attended by a large % of apparent cures. FRANCES KRASNOW

Schistosomiasis treated with antimony sodium thioglycollate and with antimony thioglycollamide. GEO. C. CHATTUCK AND PAUL T. WILLIS. Harvard Med. School. *J. Trop. Med.* **31,** 115–6(1928).—Both drugs markedly aided schistosomiasis cure. Put up in powdered form in capsules, they withstood the climate of tropical Africa for more than a yr. but finally deteriorated. In soln., Sb Na thioglycollate decomposes readily but Sb thioglycollamide seems to be stable. FRANCES KRASNOW

Sodium oleate and titanium-lipase in cancer treatment. D. GARDNER. *J. Trop. Med.* **31,** 194–6(1928).—Na oleate given in tablet form showed good results. An aq. soln. of lipase obtained by the Willstätter method, when treated with 10% Ti tetrachloride, gives a white powder. This compd. administered by mouth was used in cancer treatment and found beneficial. FRANCES KRASNOW

The effects of adrenaline on respiration. J. S. M'DOWALL. Univ. of London. *Quart. J. Exptl. Physiol.* **18,** 325–32(1928).—Reduction of respiration is followed by an increase if stimulation by other means is avoided. Adrenaline apnea is produced in a manner similar to and coincident with the vagal inhibition of the heart caused by adrenaline. Ergotoxine or ergotamine brings about a rapid, shallow, respiration which may be preceded by an evanescent reduction. After ergotoxine, adrenaline apnea is not only abolished, but adrenaline may cause a marked increase in respiration. If repeated, adrenaline may cause complete failure of respiration. FRANCES KRASNOW

The toxic effects of amines. A. R. JOHNSTON. Univ. of Cincinnati. *J. Infectious Diseases* **42,** 473–84(1928).—Death from the amines studied is the result of respiratory failure. No relationship exists between the no. of NH_2 groups in the mol. and its toxicity, including its edema-producing qualities. Pyridine and quinoline in which the N is bound with the ring produce general anesthesia Cadaverine and putrescine are not toxic, and fuchsin is only slightly so as compared to the markedly toxic p-$C_6H_4(NH_2)_2$. p-$C_6H_4(NH_2)_2$ on living rabbits manifests its action first peripherally (loss of locomotion), second by early acceleration of respiration, third by salivation, sonorous and labored breathing, edema of the tongue, nose, face, neck and salivary glands, or if sufficient amt. be given clonic seizures terminate the life of the animal before the edema stage is reached. It produces marked rigor in frogs. The hydrochloride is less toxic and has less edema-producing qualities than the base. $CaCl_2$ given with the compd. partially antagonizes its action. Tolerance to it is not obtained. Various amines have predilection for different tissues of the same animal. p-$C_6H_4(NH_2)_2$ has predilection for the same tissues removed from the body as in the living animal. Amines affect the action of the exposed intact frog heart but only in concns. above those tolerated in the living animal. Basic amines cause an increase in both muscle rigor and the swelling of muscles; both the rigor and swelling are greater than those produced by acids at any concn. The salts of the basic amines diminish both the rigor and swelling of muscles. Increased swelling of muscles may occur with relaxation. J. H. LEWIS

The combined action of convulsant drugs. L. SCREMIN. *Arch. sci. biol.* (Italy) **12,** 262–76(1928).—The combined action of convulsant drugs was studied: those whose action results in general contraction of a tetanic nature of all striated muscles (strychnine, codeine, caffeine, thebaine, narcotine, hydrastine, apomorphine, pyramidone and cocaine), also, those which give rise to intermittent shock or clonic contractions (picrotoxin, acetone, phenol, hydroquinone and nicotine). Two drugs at a time were studied. To insure the simultaneous action of the drugs, they were injected intravenously into rabbits of medium wt. Preliminary expts. were made to det. the minimum convulsive dose of each single drug. The pharmacol. action of the association of the two drugs was then detd. As a rule the two were mixed before injection. Complete data are given for three series of expts.: (1) strychnine-caffeine, (2) strychnine-narcotine, (3) strychnine-codeine. These represent 3 possibilities: unaltered, increased or diminished action. The results are also shown in graphical form in which the doses of caffeine or narcotine, or codeine are plotted as abscissas, and those of strychnine as ordinates. The diagonal straight line connecting the min. convulsive dose of strychnine with that of caffeine, narcotine or codeine is the locus of all points representing values corresponding to the summation or unaltered effect of the two drugs. Min. convulsive doses which fall below the diagonal show synergism or increased action, and those which fall above the diagonal show "degradation" or diminished action. When strychnine and caffeine act simultaneously in doses whose sum falls below the diagonal, the drugs very often remain inactive. By keeping the dose of strychnine close to the min. convulsive dose and gradually increasing the dose of narcotine, $^2/_3$ the min. dose of the latter must be

used to obtain an action with strychnine slightly less than the min. The behavior of strychnine and codeine is variable depending upon whether the dose for codeine is greater or smaller than 0.00011 g. mol. per kg. Other results: strychnine-thebaine, the combined action shows summation in all doses except for the proportion 0.5 to 0.5, which tends toward synergism; strychnine-hydrastine behave similarly; strychnine-phenol, strychnine-pyramidone, strychnine-apomorphine and strychnine-cocaine show "degradation" but in certain proportions the degradation is small and approaches summation. The conclusion from these results is that summation, synergism and "degradation" are not absolute and const. factors, but vary as a function of the ratio in which the drugs are united. PETER MASUCCI

Barbiturism. G. CORONEDI. *Arch. sci. biol.* (Italy) **12,** 299–305(1928).—The toxicological and pharmacol. action of alkyl derivs. of barbituric acid are being investigated exptly. and clinically. Following the oral introduction of these derivs., 90% of the drug has been shown to disappear from the stomach of a dog 3–4 hrs. after introduction. Elimination is principally through the kidneys. In man the rate of excretion of veronal per day was: 1st day 0.10 g., 2nd 0.03 g., 3rd 0.03 g., 4th 0.025 g. The drugs tend to deposit as follows: in man brain 0.106%, liver 0.030%; in rabbit brain 0.086%, liver 0.008%. Clinical observations indicate that serious disturbances take place in the respiratory tract 2–3 days after acute barbituric poisoning, culminating in pneumonia with fatal results. This complication in the respiratory tract has been observed in every age and sex and in very healthy individuals prior to the poisoning. P. M.

An arrow poison with heart action from Colombia, South America. C. G. SANTESSON. *Acta Med. Scand.* **68,** 287–304(1928).—An arrow poison acting on the heart coming from the new world is demonstrated for the first time. It comes from an as yet unknown tree of northwest Colombia It is obtained from the sap which flows from a circular incision in the bark. It contains a bitter and poisonous glucoside which, especially in the frog, produces typical systolic cardiac paralysis. Its action varies according to the animal. Thus, for frogs the toxic dose is 0.6 mg. per kg.; 1.0 mg. per kg. in rabbit and 22–30 mg. per kg. for chickens and mice, resp. The identity of this poison with the Pakurú-sap is not at all certain. S. MORGULIS

Two arrow heart poisons from the interior of East Africa. C. G. SANTESSON. Medico-chirurg. Inst., Stockholm *Skand. Arch. Physiol.* **54,** 175–88(1928). S. M.

Studies on the elimination of triphenylmethanesulfonic acid and carbinols in the urine. G v. FARKAS, G GYARGYI AND L. NÉMETH. *Biochem. Z* **187,** 363–8(1927).—The carbinolization of the triphenylmethanesulfonic acid dyes depends on the H-ion concn of the organism. It is difficult to decide whether the carbinol is in a finer state of dispersion than the dye. S. MORGULIS

The influence on blood formation and the metabolism of feeding active iron oxide and radiothorium in normal rabbits as demonstrated by the urinary carbon : nitrogen quotient. A. ALLEN GOLDBLOOM. *Biochem Z.* **192,** 250–71(1928).—Daily administration of 5 mg. active Fe_2O_3 ("Siderac") and of 75 Maché units of radiothorium in normal rabbits receiving a normal diet increases the urinary C:N quotient but does not cause an increase in the red cells. But with 150 Maché units of radiothorium and 5 mg. Fe_2O_3 per kg. and per day there was a rise in the number of erythrocytes in normal rabbits. **The influence of radiothorium on the urinary carbon : nitrogen quotient.** *Ibid* 272–97.—Repeated daily doses of radiothorium (22–240 Maché units per kg. and per day) causes a rise in the urinary C:N quotient depending upon the dose. A single intravenous injection of radiothorium (150–5000 Maché units) causes a gradually increasing C:N quotient. The change is usually due to alteration in both the C and N excretion but not infrequently to the increase in C or to a decrease in N. The limiting effect of small doses of radiothorium on oxidation is thus shown. Even after feeding for many weeks 120–240 units of radiothorium per kg. and per day none unless it be very minute traces becomes absorbed and is retained in the organism. S. MORGULIS

The distribution of bismuth in the blood. SVEND LOMHOLT. Städtisches Krankenhaus, Kopenhagen. *Biochem. Z.* **198,** 98–102(1928).—Bi is very largely combined with the plasma proteins and in equal amts. in the 3 fractions pptd. (1) by 1.37% $(NH_4)_2SO_4$; (2) by 50% $(NH_4)_2SO_4$; or (3) by heat. A small amt. seems to be bound by the white blood cells, while the red cells contain practically no Bi. The ultrafiltrate of the plasma is practically free from Bi, nor is any contained in the lecithin pptd. at 15° with abs. alc. S. MORGULIS

Transformation of benzene in the organism and methods of its determination. IDA D. GADASKIN. Lab. des Arbeitskommissariats. Baku. *Biochem. Z.* **198,** 149–56 (1928).—Poisoning with benzene is a composite effect of the toxic action of C_6H_6 and of

its oxidation product, C_6H_5OH. A colorimetric procedure is described for the benzene detn. in blood which is claimed to be of sufficient accuracy. S. MORGULIS

The response of chronic nephrosis to parathyroid and thyroid medication. D. S. LEWIS AND W. DEM. SCRIVER. McGill Univ., Montreal, Canada. *Ann. Internal Med.* **2**, 66–82(1928).—Four cases of chronic nephrosis were studied. One was a pure chronic or lipoid nephrosis; the others were chronic nephrosis with glomerulo-nephritis. The first case showed a marked response to parathyroid ext. while the second and third showed no response. The second became edema free after all treatment had been discontinued. The third became edema free following massive doses of thyroid ext. The fourth showed a rapid advance of the disease following thyroid medication. In no instance was the albuminuria affected by treatment, nor did the plasma proteins or albumin-globulin ratio show noticeable change, even when marked symptomatic improvement occurred. JOHN T. MYERS

Purpuric skin manifestations following the use of merbaphen. ALBERT M. SNELL AND LEONARD G. ROWNTREE. Mayo Clinic, Rochester, Minn. *Ann. Internal Med.* **2**, 97–103(1928).—If used cautiously, merbaphen has little untoward effect. It may be that its action as a diuretic depends on an effect on the capillary epithelium. When it causes purpura it may be merely exercising its usual effect, but on capillaries injured by disease. Hence purpura may be an expression of the underlying disease as well as an evidence of the true toxic effect of the drug. JOHN T. MYERS

The treatment of endamebiasis. PHILIP W. BROWN. The Mayo Clinic, Rochester, Minn. *Ann. Internal Med.* **2**, 177–91(1928).—The org. arsenicals and yatren seem to be valuable addns. to the treatment of endamebiasis. A combination of As and emetin is best. Auremetin by mouth may supplant emetin hypodermically. Treparsol and stovarsol are equally effective, but the former is preferable because it is eliminated rapidly. As produces a small per cent of reactions and should be used with care. Certain cases seem resistant, but with variation of drugs a cure can be secured in most instances. JOHN T. MYERS

The abuse of digitalis. WALTER A. BLOEDORN. *Ann. Internal Med.* **2**, 261–8 (1928).—Digitalis has a narrow margin of safety. Its use should never be left to untrained hands. JOHN T. MYERS

Diabetic therapy, with special reference to the newer remedies. ARTHUR A. HEROLD. *Ann. Internal Med.* **2**, 269–74(1928).—Our main reliance should be placed on diet and insulin. Some substance as synthelin may replace insulin in routine treatment but not in coma. JOHN T. MYERS

The effect of injections of hydrochloric acid on the gastric and duodenal mucosae. WM. J. GALLAGHER. Univ. of Chicago. *Arch. Surg.* **17**, 613–26(1928).—In one group of 7 dogs with jejunal transplants to the stomach, HCl was injected daily by stomach tube in amts. of from 200 to 225 cc. of a 0.22, 0.29 or 0.62% soln. Vomiting was frequent and mucus was present in large quantities. There was frequently some delay in the emptying time of the stomach. Acute ulcers appeared in the pyloric mucosa of 2 animals and a chronic ulcer in the fundal mucosa of one. The latter may have been due to repeated trauma of the stomach tube. The most constant findings were acute and chronic gastritis with multiple erosions, which were more marked with higher concns. of acid. A localized area of duodenitis, with erosions in 2, appeared in 4 of the animals. In a group of six control animals, a 0.62% soln. was introduced in similar amts. 2 or 3 times daily. Chronic ulcers were not observed. Other changes were similar but less marked. There was no delay in the emptying time of the stomach. HCl seems to be a factor in the etiology of gastric ulcers. Mucus may exert a protective action. JOHN T. MYERS

The mechanism of lead poisoning. Bone marrow changes in experimental lead poisoning. J. SPERANSKI AND R. SKLIANSKAJA. Staatlich. Wiss. Inst. f. Arbeitsschutz in Moskau. *Folia Haematol.* **36**, 289–315(1928).—The morphology of bone marrow in normal guinea pigs is quite const., and there are only a few unimportant variations in different bones. The pathological changes produced by the same poison are the same in different bones. In guinea pigs, Pb poisoning stimulates both the erythroblastic and the leucoblastic systems, but the former reacts so much more actively that the latter may be almost obscured. The intensity of the reaction depends on the dose of Pb, and the no. of injections. With 160 mg. of white lead per kg. per day of animal body wt., the pig usually dies before bone marrow changes appear. 120 mg. will cause a definite reaction, and 35 to 70 mg. will cause an intense reaction. In such Pb poisoning, the erythroblasts reach 60%, the normal being about 30%. The most noticeable increase is in immature cells as proerythroblasts, and macroblasts. In very marked reactions there is a myelogenous metaplasia of the spleen. Following hemorrhage or

therapeutic doses of As, there is a similar erythroblastic reaction. In Pb poisoning there is a close relationship between blood changes and bone marrow changes.

JOHN T. MYERS

The fate of colloidal iron administered intravenously. CYRIL J. POLSON. Victoria Univ. of Manchester. *J. Path. Bact.* **31,** 445–60(1928).—After the intravenous injection of colloidal Fe into rabbits, the greater part is held in the lungs, liver and spleen. Most of the Fe in the lungs is present as emboli in the vessels, while in the liver and spleen it is ingested by the endothelial cells. The lung Fe is removed from the vessels by phagocytes believed to be derived from lung epithelium. When the Kuppfer cells are charged with Fe they tend to be detached from the capillary walls and to collect in the lumina. Later they appear to fuse and form large multinuclear giant cells, like foamy "foreign body" giant cells. Fe enters the parenchymal liver cells later only, being transferred from the Kuppfer cells, none entering directly. Aggregation of the splenic phagocytes occurs, and by the end of the second week the cells degenerate, leaving granular depots of Fe in the splenic pulp. While embolism of the kidney glomeruli may be an immediate result, Fe is not found in the epithelium of the tubules until the end of the second week unless the tubules have been previously damaged. There is some evidence of an incerase in the bone marrow content of Fe. Fe appears to collect in the thoracic and abdominal lymph nodes and in the cecum which excretes it. The Fe in the other organs is scanty and restricted to the endothelium of the capillaries for the most part. Chem. examination shows that the amt. of Fe held by the lungs after a single dose depends on the degree of pulmonary embolism. Afterward there seems to be a transfer of Fe from lung to liver, the mechanism of which is unknown. There is a good bibliography. JOHN T. MYERS

The action of adrenaline chloride on the human heart. W. E. HUME. *Quart. J. Med.* **21,** 459–62(1928).—When adrenaline-HCl is injected into the vascular system of man it would seem to have a direct effect on the heart muscle as well as on the myoneural junctions of the sympathetic system. The injection of 10 minims subcutaneously may produce severe cardiac distress which is practically always temporary. The effect on the heart when given intravenously seems to vary directly with the diln. Five minims dild. with 4 or 5 vols. of water has less direct effect than 2.5 minims dild. with 1 vol. of water. Many electrocardiographic records of the effect of digitalis in the human are given. JOHN T. MYERS

The use of synthalin in the treatment of diabetes mellitus. GEORGE GRAHAM AND G. C. LINDER. St. Bartholomew's Hosp., London. *Quart. J Med.* **21,** 509–21 (1928).—Synthalin has an effect on glucemia and glucosuria of diabetics, but in this series it only acted in 8 out of 12 cases. The toxic symptoms are serious and should be avoided by small dosage with careful spacing. It should only be used if the patient will not try insulin. JOHN T. MYERS

The evolution of therapeutics. E. FOURNEAU. *Chimie et industrie* Special No., 475(April, 1928).—A brief outline of the development of the use of synthetic drugs in therapeutics since the beginning of the 19th century. A PAPINEAU-COUTURE

Insulin, phytochinine and Funk's factor. A. CONDORELLI. *Paris-médical* **18,** 89(1928); *Bull. soc. hyg. aliment.* **16,** 250(1928).—From the leaves of Gramineae C. isolated a substance which he designates as phytochinine and which has an exceptionally interesting action on the metabolism of carbohydrates. It has no action on the hyperglucemia due to injection of adrenaline, but reduces the hyperglucemia due to subcutaneous or endovenous injection of glucose, as well as the glucemia of dogs from which the pancreas has been removed and the glucemia of human diabetes. It seems to be identical with the factor A isolated by Funk from insulin. A. PAPINEAU-COUTURE

Investigations on calcium fixatives. G. MOURIQUAND, A. LEULIER, M. BERNHEIM AND (MISS) J. SCHOEN. *Presse médicale* No. **14,** 209(1928); *Bull. soc. hyg. aliment.* **16,** 247–8(1928).—When sufficient Ca is offered to the organism it frequently does not assimilate it, especially in pathological conditions, unless suitable fixatives are present. The action on exptl. rickets in rats of various substances which might act as such was investigated. Adrenaline (7 drops of 0.1% soln. *per os* or $^1/_{16}$ cc. subcutaneously, every 2 days), parathyroid powder (0.25 mg. per day *per os*) and thyroid powder had no prophylactic effect, adrenaline having a decalcifying effect. Cod-liver oil in small doses (3 drops per day per animal), ultra-violet light, Wood's light and milk powder which had been exposed to ultra-violet light exhibited antirachitic properties. Application of these results to human rickets and tuberculosis is briefly discussed.

A. PAPINEAU-COUTURE

The influence of calcium and potassium upon the action of certain cardiac drugs upon the isolated frog heart. S. L. GAUKHMAN AND E. S. GUREVICH. State Inst.

Exptl. Med., Leningrad. *Arkh. Biol. Nauk* **28,** 285–96(1928).—The effects of *strophanthin* and of *adrenaline* upon the frog heart were studied with varying concns. of Ca and K in the perfusion fluid. Ca produces a positive inotropic effect and negative chrono- and dromotropic effects. Toxic doses of Ca arrest the heart in ventricular systole. Absence of Ca has a negative inotropic effect and arrests the heart in ventricular diastole. The heart is twice as sensitive to changes in K concn. as to those of Ca. K produces negative ino- and chronotropic effects and arrests the heart in ventricular diastole. Perfusion fluid totally devoid of Ca and K is less toxic than one devoid of Ca alone. The toxic effect of strophanthin is directly and strictly proportional to the Ca concn. The stimulating effect of strophanthin is particularly manifest with the diminution of the Ca. Increase in the K concn. diminishes the stimulating and toxic effects of strophanthin. The action of adrenaline is also intimately connected with the concn. of Ca and K, inversely for Ca and directly for K. The regularity of the dependence of the action of cardiac drugs upon Ca and K concns. is emphasized, but the explanation of the problem still awaits solution. W. A. PERLZWEIG

The decomposition of dextrose in toxic insulin action. FISCHLER. *Münch. med. Wochschr.* **74,** 680–2(1928).—The toxic effects of insulin are due to an abnormal decompn. of dextrose and to an increased rate of formation of methylglyoxal. Traces of CHI_3-forming substances were recovered from the blood and muscles of animals poisoned with insulin. W. A. PERLZWEIG

The injurious action of potassium cyanide on the skin and on the human organism. HEINZ LANGE. *Metall* 1927, 85–6; *Chem. Zentr.* **1927,** II, 723.—The irritant action of KCN on the skin is described and the necessary precautions are given for industrial plants. J. S. REICHERT

Chemical irritation and poisoning. A. PÜTTER. *Sitzb. Heidelberg Akad. Wiss.* **1927,** No. 4, 3–27; *Chem. Zentr.* **1927,** II, 713.—Psychological studies on the relation between irritation and poisoning, and their swelling action. J. S. REICHERT

The action of ergotoxine in the mammalian heart. HAROLD L. OTTO. Univ. of Vienna. *J. Pharmacol* **33,** 285–93(1928).—Accelerator nerve action after ergotoxine and ergotamine was tested by the effect of faradic stimulation of the nerve trunks, or intravenous injection of adrenaline. Ergotoxine and ergotamine had little effect on the accelerator nerve mechanism of the heart in the cat and the dog. C. RIEGEL

The anuran in bio-titration of pituitrin. A. J. MCLEAN. Harvard Med. School. *J. Pharmacol.* **33,** 301–19(1928).—Expansion of melanophores in frog skin on perfusing the hind legs of a frog with a soln. contg. pituitrin is used as a method for detecting the presence of hypophyseal posterior lobe principle. The H-ion concn. of the perfusing fluid must be carefully controlled to make the results valid. Hypophysectomized tadpoles immersed in the fluid to be tested serve as crude indicators of the presence of posterior lobe principle. C. RIEGEL

Studies of chronic morphine poisoning in dogs. I. General symptoms and behavior during addiction and withdrawal. O. H. PLANT AND I. H. PIERCE. Univ. of Iowa. *J. Pharmacol* **33,** 329–57(1928).—Symptoms and behavior are recorded in cases of 24 addictions to morphine and 22 withdrawals. There was considerable variation in individuals and these differences were not dependent on length of addiction or size of dose at withdrawal. On the whole the symptoms show marked similarity to those observed in chronic morphine poisoning in man. **II. Changes in blood cells and hemoglobin during addiction and withdrawal.** I. H. PIERCE AND O. H. PLANT. *Ibid* 359–70.—During the period of addiction to morphine changes in red cells, white cells and Hb are not marked. During withdrawal there is a marked leucocytosis, with an increase in percentage of polynuclear neutrophiles. Red cells and Hb decrease during the period of withdrawal. **III. Blood sugar during tolerance and withdrawal.** *Ibid* 371–85.—The general level of blood sugar is higher during the 1st half of addiction than during the control period, and is lower during the 2nd half of addiction than during the 1st half, and sometimes lower than during the control period. For the 1st week or 10 days of addiction the injection of morphine is followed by a hyperglucemia of gradually decreasing degree. Later in addiction there is no increase in blood sugar after injection of morphine, although increases in dosage produce a slight elevation for a few days. This tolerance is rapidly lost when the drug is withheld. Immediately after withdrawal the blood sugar increases, usually reaching a max. in 2 to 5 days. Blood sugar then returns to a normal level. C. RIEGEL

The therapeutic value of etharsanol and proparsanol in experimental trypanosomiasis in rats and rabbits. W. K. STRATMAN-THOMAS AND A. S. LOEVENHART. Univ. of Wis. *J. Pharmacol.* **33,** 459–77(1928).—Rats and rabbits were infected with *T. brucei, T. equiperdum, T. equinum, T. Lewisi, T. Rhodesiense.* Subsequently etharsanol

or proparsanol was given. Etharsanol cured infections even when the drug was administered only late in the disease. Proparsanol was not as effective. C. RIEGEL

The therapeutic action of the monosodium salts of 2-*p*-arsonoanilinoethanol and 3-*p*-arsonoanilinopropanol in experimental rabbit syphilis. G. E. WAKERLIN AND A. S. LOEVENHART. Univ. of Wis. *J. Pharmacol.* **33**, 479–82(1928).—Both etharsanol and proparsanol have good healing properties. C. RIEGEL

Antagonism and reversals of contracted crop (esophageal) muscle caused by a variety of muscular stimulants. P. J. HANZLIK AND E. M. BUTT. Stanford Univ. *J. Pharmacol.* **33**, 483–95(1928).—Contracted circular muscle of the pigeon crop can be caused to relax by a no. of compds., including epinephrine, ergot, guanidine, pilocarpine, pituitary and tyramine. The antagonistic action is partial or complete, and with epinephrine and guanidine reversals are obtained. However, a given stimulant does not antagonize or reverse its own action. C. RIEGEL

Studies on crystalline insulin. VI. Further contributions to the question whether or not crystalline insulin is an adsorption product. VINCENT DUVIGNEAUD, E. M. K. GEILING AND C. A. EDDY. Johns Hopkins Univ. *J. Pharmacol.* **33**, 497–509(1928).—Cryst. insulin is dissolved in HCl, adsorbed on charcoal, and the charcoal extd. with phenol. A ppt. is obtained by addn. of water to the phenol soln. The dried ppt. has the same potency as the original insulin. The ppt. is extd. with Na_2HPO_4. The soln. obtained is active, as is also the residue, which can be dissolved in a fresh portion of phosphate. The powder obtained from the phenol soln. can be crystd., and the crystals so obtained are identical in cryst. form, behavior and activity with the original insulin. The results do not confirm the findings of Dingemanse, who reports obtaining a compd. more active than cryst. insulin by a procedure similar to that used here. **VII. The acetylation of crystalline insulin, and the behavior of insulin towards alkali.** H. JENSEN AND E. M. K. GEILING. *Ibid* 511–20.—An acetylated product is obtained by treating cryst insulin with Ac_2O at 0°. This compd. is only $^1/_5$ as active as the original insulin. Insulin does not undergo any marked change on treatment with 0.01 *N* NaOH. Acetyl insulin is dissolved, and the soln. is 3 times as active as acetyl insulin, although only $^1/_2$ as active as the original insulin. 0 01 *N* NaOH splits off H_2S from acetyl insulin, and it is thought that the lower activity of the regenerated insulin is assocd. with the liberation of H_2S. The splitting off of H_2S indicates the S in acetyl insulin is more labile than in insulin. C. RIEGEL

A comparative study of the prophylactic and sterilizing properties of certain organic arsenical and mercurial compounds in experimental rabbit syphilis. G. E. WAKERLIN AND A. S LOEVENHART. Univ. of Wis. *J. Pharmacol.* **34**, 15–22(1928).—To det. the prophylactic properties of the drugs, rabbits were inoculated with *Tr. pallidum*, and 24 hrs. later were given an injection of the drug to be tested. To det. sterilizing properties, 3 weekly injections of the compd. were given 8 weeks after infection. Arsphenamine and neoarsphenamine were effective in prophylaxis and in sterilizing. Tryparsamide was a relatively poor prophylactic agent and had no sterilizing power. Proparsanol, flumerin and sodium 1-mercuribis-3-nitronaphthalene-8-carboxylate had no prophylactic or sterilizing powers. It is suggested that because of the parallelism between prophylactic and sterilizing powers, and the shorter time consumed in detg. the former, that method be used in evaluating the therapeutic activity. C. RIEGEL

The therapeutic action of certain organic mercurial compounds in experimental rabbit syphilis. G. E. WAKERLIN AND A. S. LOEVENHART. Univ. of Wis. *J. Pharmacol.* **34**, 23–8(1928).—Mercuric salicylate and flumerin possess definite healing power in exptl. rabbit syphilis. Sodium 1-mercuribis-3-nitronaphthalene-8-carboxylate has comparatively little heating power. C. RIEGEL

The electromotive action of drugs as a cause of their toxicity. IV. The augmentor effect. R. BEUTNER. Univ. of Louisville. *J. Pharmacol.* **34**, 29–36(1928).—The drop in e. m. f. caused by adding pilocarpine to a system: Calomel electrode||nitrobenzene + oleic acid||Tyrode soln.||calomel electrode$^+$ is increased when Na oleate is present within a definite range of concn. This effect is similar to the augmenting effect of Na oleate on the constricting action of pilocarpine on isolated intestine in Tyrode soln. C. RIEGEL

The reversal by ergotamine of the effect of ephedrine on the blood pressure. F. R. CURTIS. Univ. of London. *J. Pharmacol.* **34**, 37–41(1928).—In cats, after ergotamine, ephedrine caused a drop in blood pressure. C. RIEGEL

Resistance to adrenaline in relation to different modes of heart arrest. E. BARDIER. *Compt. rend. soc. biol.* **98**, 1408–10(1928).—The sensibility of the heart to adrenaline is diminished in hemorrhage and is entirely suppressed in asphyxia. L. W. R.

Effect of phenylhydrazine and sodium nitrite on the blood. GY. PETRÁNYI.

Magyar Orvosi Arch. **29,** 202-14(1928).—The total quantity of the blood is lowered by phenylhydrazine-HCl treatment. This effect is due chiefly to the diminished quantity of blood cells, whereas the vol. of the plasma is usually increased. There were seen in the blood small bodies which probably originate from the destroyed blood cells, and their presence can be regarded as a sign of degeneration. Animals treated with $NaNO_2$ have the total vol. of the blood slightly decreased. The decrease is compensated by a marked regeneration which is not a sp. effect on the bone marrow but is probably a secondary effect to compensate cell destruction. Doses of 0.15 to 0.45 g. of $NaNO_2$ produced no undesirable symptoms except to increase the action above described. L. W. Riggs

Preliminary estimation of the vascular activity of ephedrine and *l*-adrenaline. L. Launoy and P. Nicolle. *Compt. rend. soc. biol.* 99, 3-5(1928).—The ratios of the activity and of the toxicity of *l*-ephedrine to those of *l*-adrenaline are, resp., 1:166 and 1:1000. Tests with the rabbit proved that with the same dose *l*-ephedrine-HCl caused about double the hypertension of that caused by synthetic racemic ephedrine-HCl. L. W. Riggs

Action of the ovarian hormone on the glucemia of the normal dog. F. Rathery, R. Kourilsky and (Mlle.) S. Gibert. *Compt. rend. soc biol.* 99, 529-32(1928).—The ovarian hormone has an action on the glucemia which is especially marked following intramuscular injections of an oil ext of the hormone. Aq. exts of the hormone even when intravenously injected are less active. In general, the folliculin ext. diminishes the glucemia of the male, and increases both in amplitude and duration the glucemia of the female dog. The hyperglucemic action of the hormone is observed in fasting glucemia. L. W. Riggs

Comparative influence of sodium bicarbonate and insulin on the urinary excretion of "acetone bodies" in the course of a water diet in the dog. F. Maignon and E. Knithakis. *Compt. rend. soc. biol.* 99, 604-6(1928); cf. *C. A.* 22, 2194.—A water diet did not cause ketosis in the dog. The administration of insulin to the fasting dog caused a diminution of both acetone and β-hydroxybutyric acid. $NaHCO_3$ has a similar action. L. W. Riggs

Action of nitrites on the gastric secretion. M. C. Mladoveanu. *Compt. rend. soc. biol.* 99, 606-10(1928).—Nitrites, and in particular $NaNO_2$, increase the vol. of the gastric secretion, the free HCl, the total acidity and the coeff. of Linossier. This increase of the gastric secretion by $NaNO_2$ is nearly equal to that caused by histamine, but its duration is less prolonged. L. W. Riggs

Action of adrenaline on muscular atony of the initial stage of curarization. F. Bremer and J. Titeca. *Compt. rend. soc. biol.* 99, 624-7(1928).—The rapid intravenous injection of adrenaline in doses of 0.08 mg. per kg. is capable of causing the transitory reappearance of the rigidity of decerebration of the cat, abolished by a previous injection of 0.25 mg. per kg. of curare. This decurarizing action of adrenaline is probably the expression of an actual antagonism between the hormone and the alkaloid. L. W. R.

Prolonged insulin hypoglucemia without symptoms. S. J. Maddock and Harry C. Trimble. *J. Am. Med. Assocn.* 91, 616-21(1928).—Following insulin administration, the blood sugar of diabetic patients and of depancreatized dogs may remain at levels of 50 mg. per 100 cc. or below for 1 to 6 hrs. without symptoms. Such periods may or may not be followed by hypoglucemic reactions. It is believed that this phenomenon, whose dangers are evident, is probably frequent in occurrence; that it is usually unrecognized, and that it may account for the difficulty so often encountered in regulating the administration of insulin. L. W. Riggs

Bactericidal action of mercurochrome-220 soluble and iodine solutions in skin disinfection. James S. Simmons. U. S. Army. *J. Am. Med. Assocn* 91, 704-8(1928).—Conclusions: Mercurochrome-220 soluble 2% aq. soln. is not effective in disinfection of the unbroken skin. The 2% alc.-acetone-aq. soln. of mercurochrome and the 5% alc. soln. are slightly better than the watery soln., but are feeble bactericidal agents on unbroken skin, as compared with I soln. The 3.5% alc. soln. of I is more actively bactericidal on the unbroken skin than any of the mercurochrome solns. tested (cf. following abstr.). L. W. Riggs

Mercurochrome and iodine as disinfectants of mucous membrane of mouth.

cannot be considered effective. I in dilns. of 3.5 or even 1.75% strength, preferably in glycerol, is an effective germicide for the disinfection of the oral mucous membranes (cf. following abstr.). L. W. Riggs

Mercurochrome-220 soluble and U. S. P. tincture of iodine. Comparison of germicidal efficiency in skin disinfection. G. F. Reddish and W. E. Drake. *J. Am. Med. Assocn.* **91,** 712–6(1928); cf. preceding abstr.—Two per cent mercurochrome in aq.-alc.-acetone soln. and tincture of I are about equally active in disinfecting the unbroken skin. A 5 min. contact of either of these disinfectants is sufficient for pre-operative skin disinfection. Because of the objections to tincture of I, the use of mercurochrome is recommended. L. W. Riggs

Intramuscular injection of dextrose. Jerome Glaser. *J. Am. Med. Assocn.* **91,** 722–6(1928).—The intramuscular administration of a 10% soln of dextrose in physiol. soln. of NaCl or distd. water is a practical and relatively safe method for raising the blood-sugar level, and is indicated in those conditions in which such a rise is desirable and other methods of administration are contraindicated. The contraindications are the presence of a known hyperglucemia, and possibly the presence of a bacteremia. The max. rise following an injection of dextrose soln. occurs within 30 min. L. W. R.

Behavior of sugar in blood and in abdominal effusions following the ingestion of dextrose. B. Bisbini. *Policlinico* **35,** 312(1928); *J. Am. Med. Assocn.* **91,** 683.—Conclusions: (1) The percentage of sugar will serve for the differential diagnosis of exudates and transudates. (2) In the exudates sugar is always present, but in much less quantity when the inflammatory symptoms are more marked. The sugar content is low in purulent fluids (3) In transudates there is always a higher sugar content—about the same as that of blood, or even higher. (4) On having the patient ingest, fasting, 50 g. of dextrose, fluctuations occur in the sugar content of the fluid and such fluctuations are minimal or nearly so in the exudate. They are much greater, however, in ascitic fluids. (5) The reason for the low sugar content in inflammatory effusions is still uncertain L. W. Riggs

Pharmacologic study of the absolute pressure of the heart. II. Study of the rabbit heart. Itaro Kikuchi. *Tohoku J. Expt. Med* **11,** 293–307(1928); cf. *C. A.* **22,** 4175. Adrenaline and digitalis compds (helleborein, strophanthin and digitoxin) cause a considerable rise in the abs pressure of the rabbit heart. Ca and caffeine cause a smaller rise in the abs. pressure, which in the case of caffeine in doses of 0.15 cc. of a 1% soln. is long in reaching a max., but the rise is more prolonged than with most of the drugs. Caffeine in a dose of 0.4 cc. of a 1% soln. caused a fall in the abs. pressure of the heart The tests with physostigmine were indeterminate. Sparteine, alc. and hexetone caused a fall in the abs. pressure. L. W. Riggs

The favorable influence of small combined alkali-belladonna doses on the acidity curve and disorders caused by acidity. Schellong. *Munch. med. Wochschr.* **74,** 1127–8; *Chem. Zentr.* **1927,** II, 1367.—Chem. tests with *gelonida stomachica* (manufacturer: Goedecke), a combination of ext. belladonnae 0.01, magnesia usta 0.6, and bismut. subnitr. 0.2. in tablets. In cases of gastric troubles on account of high gastric acidity good results were seen. G. Schwoch

Local vitamin application in skin diseases. H. Beck. *Münch med Wochschr.* **74,** 1129–30; *Chem. Zentr.* **1927,** II, 1365.—Local vitamin application in skin diseases is reported. The prepn. *vitrisol* (manufacturer: Dr. Schwabe, Leipzig), which is manufd. from spinach and submitted to a prolonged radiation with ultra-violet light, was employed. Besides pyoktanin, vitrisol contains various inorg. salts present in small quantities. In acne vulgaris and lupus vulgaris good results were obtained. The drug was applied by means of ionthophoresis. G. Schwoch

The role of magnesium phosphate in fatigue and rigor mortis of the muscle. Leonhard Wacker. *Münch. Med. Wochschr.* **74,** 1222–3; *Chem. Zentr.* **1927,** II, 1371.—Mg phosphate deposited in the resting muscle partly in insol. form goes into soln. to a considerable extent in case of fatigue and rigor mortis, because of the influence of the KH_2PO_4 forming. In rigor mortis more Mg phosphate is dissolved than in fatigue. In the alk. rigidity, the formation of lactic acid is very small and the KH_2PO_4 content low. Therefore, a much smaller quantity of Mg phosphate goes into soln. than in the case of acid rigidity. The known paralyzing effect of the Mg ions on the motor nerve-endings justifies the conclusion that Mg phosphate exerts a regulating action in the muscle. G. Schwoch

Accurate observation of some uncommonly protracted lead poisonings. A. Seitz. *Münch. med. Wochschr.* **74,** 1364–5; *Chem. Zentr.* **1927,** II, 1732.—Clinical report on Pb poisoning of 6 persons by drinking water contg. Pb. The beginning of the poisoning lies more than 15 years back. In 1920, the drinking water of certain buildings contd. 8 mg., at a later examn. 36 mg. Pb per l. In spite of changing the pipes giving off the Pb, the drinking water still had 2.6–2.9 mg. Pb per l. in 1927. In none of the cases the characteristic blue line on the gums was to be seen; on the other hand all the rest

of the symptoms of chronic Pb poisoning were present. In one of the patients tuberculosis brought forth a renewal of Pb poisoning symptoms which had vanished. The symptoms were now those of an acute Pb poisoning with articular pains followed by paralysis of the radial nerve, evidence for the persistence of the Pb deposits in the body and their slow excretion. Administration of I brought relief, though not recovery because of the long existence of the disease. G. SCHWOCH

The problem of chronic hydrogen sulfide poisoning. RODENACKER. *Zentr. Gewerbehyg. Unfallverhüt.* **14,** 205–7; *Chem. Zentr.* **1927,** II, 1187.—R. discusses the rapid fatal action of inhaled H_2S gas when present in a concn. of over 0.15 vol. %. Death sets in as a result of inner suffocation, because the organism quickly loses the ability to utilize O_2. Local disturbances of oxidation as seen in the form of skin eruptions and catarrhs of the eye appear already at a concn. of 0.015–0.115%, if skin or mucous membranes are exposed to a H_2S-contg. atm. for a certain length of time. The removal of the poison according to Warburg by means of the catalytic action of org. Fe compds. of the cell can be much hastened by intravenous injection of a suitable Fe prepn. On account of a large number of blood tests on laborers of factories with an atm. rich in H_2S, R. concludes that, though the personal sensitiveness toward H_2S may be different and may be augmented by certain diseases, a chronic poisoning is out of question, as the poison is continually removed, and when the limit of tolerance is reached, the gas is also excreted by respiration. Besides this, H_2S is formed and resorbed again in the mouth and intestine of all human beings; perhaps it also influences the peristalsis of the colon. In sufficiently low concn., H_2S is without danger for the processes maintained by oxidation as well as for those maintained by fermentation, even when instead of an Fe compd. a Cu compd. serves as the oxidative enzyme. G. SCHWOCH

The clinical picture of chronic lead poisoning. GEORG THOMA. *Zentr. Gewerbehyg. Unfallverhüt.* **14,** 212–5; *Chem. Zentr.* **1927,** II, 1187.—T. describes first the symptoms of the acute Pb poisoning which produces in the animal a central irritant effect, and intravenous S therapy with $Na_2S_2O_3$, which is being tried especially in America. He mentions the numerous sources for Pb poisoning and discusses thoroughly the clinical and other symptoms in chronic cases, the great difficulty and importance of early recognition, the variety of the disturbances occurring and the kinds of treatment. G. S.

Toxicity of the aromatic nitro compounds: the dinitrophenol. KOELSCH. *Zentr. Gewerbehyg. Unfallverhüt.* **14,** 261–8; *Chem. Zentr.* **1927,** II, 2082.—The general toxicity of *o,p*-$(NO_2)_2C_6H_3OH$ (I) is not so large as the one of the nitrated benzenes; nevertheless, I has to be counted among the more serious substances. This is true also for all its isomers. The tolerable dose by swallowing as well as by dust resorption lies between 0.02 and 0.03 g. per kg. body wt. Death is caused quickly by 0.05 g. Simultaneous intake of alc. increases the effect of the poison. When inhaling the vapors of melted I, the irritant effect of the O-N compds. prevails. Also through absorption by the skin, quantities of the poison causing death or disease may be taken in. The crit. doses for this process of absorption are 8 to 10 times as high as for the intake by mouth. In almost all the animals the kidneys were damaged. In protracted expts. also in the liver fat infiltrations could be repeatedly demonstrated; occasionally also a central fatty degeneration of the liver lobes could be seen. I seems to act by generally injuring the protoplasm. The action upon the blood could not be explained clearly. A special action on the central nervous system and the respiratory center does not seem to exist. For the industrial practice, caution and observation of the known protections are entirely necessary. For detecting I, the suspension of strips of white cotton is recommended.
G. SCHWOCH

Studies on lipochromes. I. The reaction of animals to the presence of carotin. CHARLES L. CONNOR. Harvard. *Am. J. Path.* **4,** 227–34(1928).—Carotin was extd. from carrots and purified. When injected intraperitoneally into guinea pigs, granulomatous lesions appeared, similar to those of familiar foreign body reactions. Carotin did not appear in the blood or urine of guinea pigs after injection or ingestion of relatively large amts. It produced no effect in a rabbit when injected intravenously.
F. B. SEIBERT

Human mercuric chloride poisoning by intravenous injection. E. L. HARMON. Western Reserve School of Med. *Am. J. Path.* **4,** 321–36(1928).—The clinical findings and pathol. lesions resulting from the intravenous injection of 5–6 g. $HgCl_2$ into humans are described. Quant. reports of the amt. of Hg found in some tissues are given in some cases.
F. B. SEIBERT

Ephedrine and ephetonin. F. R. CURTIS. Univ. London. *Lancet* **1928,** II, 226.—Ephedrine and ephetonin, which are optical isomers having the empirical formula $C_6H_5.CHOH.CH.CH_3.NH.CH_3$, are used in the treatment of asthma. They produce

dilatation of the bronchi similarly to adrenaline. The former is levo-rotatory and the latter optically inactive. Compared with adrenaline, 4 mg. of ephetonin and 2 mg. of ephedrine gave an equiv. effect and this is to be expected from the fact that 4 mg. of ephetonin contains 2 mg. of ephedrine and 2 mg. of inactive *d*-ephedrine. F. B. S.

Extent of storage of scilla glucosides in the frog heart. TH. OLIARO AND E. ROTHLIN. *Arch. exptl. Path. Pharm.* **131,** 138–51(1928).—The retention of scilla derivs. by the isolated frog heart was detd. by ascertaining the limiting concn., *i. e.*, the difference between the initial and end concns. of the glucoside. For scillaria A the limiting concn. was 1:900,000; for scillaria B 1:1,300,000 and for the natural mixt. of the glucosides (Sq. 1005) 1:1,000,000. For ventricular arrest the toxic doses (in mg.) were: scillaria A 0.00009; scillaria B 0.000145, Sq. 1005 (0.00011). Within fluid vol. limits of from 0.5 to 3.0 cc. arrest of the ventricle by scillaria A is dependent upon the abs. amt. of toxin per cc., the smaller the vol. the greater the necessary amt. of toxin per cc. G. H. S.

Action of apomorphine. E. NAVRATIL. Univ. Grag. *Arch. exptl. Path. Pharm.* **131,** 159–70(1928).—Apomorphine reduces the size of the pulsation and impairs auriculo-ventricular conduction, effects which are removed by washing with Ringer soln., when the heart shows a diminished susceptibility to adrenaline, Na oleinate, choline, acetylcholine and muscarine. The changes induced by apomorphine are practically irreversible. Under the same conditions the inotropic effect of stimulating the vagus or the accelerans is abolished, not because of paralysis of the nerves, but rather because the vagus and accelerans substances produced are inactive. Apomorphine does not alter the effect of $BaCl_2$ upon the heart. With blood vessel prepns. apomorphine treatment interferes with the action of adrenaline but not with that of $BaCl_2$. Apomorphine does not modify the action of adrenaline on the blood pressure of rabbits. G. H. S.

Comparison of intra-arterial and intravenous administration of poisons. O. EHRISMANN. Univ. Berlin. *Arch. exptl. Path. Pharm.* **131,** 171–85(1928).—Aside from the local anesthetics, atropine, codeine, thebaine (and morphine to some degree) and inorg. K and Ca are less active, insofar as lethal dose for guinea pigs is concerned, when injected into the artery than when given intravenously. Unlike KCl, NaCl is less toxic injected intracardially than when introduced into artery or vein. Adrenaline and *p*-hydroxyphenylethanolmethylamine are less active when injected into the artery. When tested through their effect on elec. irritability, the action of atropine, as well as that of nicotine, was as pronounced after intraarterial as after intravenous injection. The curve of serum Ca, following administration of $CaCl_2$, was the same after both methods of administration. Three factors—differences in local distribution, chem. destruction, and tissue absorption—play a role in the diminished toxicity after injection into the artery. G. H. S.

Effect of mucilaginous substances. GERHARD SCHÖNE. Friedrichs-Univ., Halle-Wittenberg. *Arch. exptl. Path. Pharm.* **131,** 186–99(1928).—The effect of a variety of mucilaginous substances—gum arabic, salep, gum tragacanth, carrageen, gelatin, calumba, althaea, agar, Iceland moss, sago and rice—upon reflex irritability to HCl in frogs was detd., only gum arabic, calumba and althaea showing any considerable activity. The degree of viscosity bears no causal relation to effect. Titrations with phenolphthalein and with Congo red as indicators showed that in the mixts. about 50% of the HCl was bound, 10% chemically, 40% loosely. The true acidity (p_H) of the mixts. amounts to only from 5 to 15% of the initially present HCl. The activity of mucilaginous substances depends in large part upon physico-chem. processes involving the adsorption of the HCl to the surface of the colloid particles. Beef blood serum behaves like a mucilaginous substance. G. H. S.

Comparison of the effects of *d*-, *l*- and *i*-camphor. VI. Studies employing the Ganter vessel preparation and the coronary circulation of the isolated cat heart. O. EHRISMANN AND W. E. ENGELHARDT. Univ. Berlin. *Arch. exptl. Path. Pharm.* **131,** 200–11(1928).—With the vessel prepn. all 3 compds. cause dilatation, but when given intravenously this is preceded by a transitory constriction. The coronary vessels are dilated by all 3 compds. G. H. S.

Proof of sedative action in animal experiments. ERWIN SCHLAGINTWEIT. Univ. München. *Arch. exptl. Path. Pharm.* **131,** 212–20(1928).—The animal under test is placed in a suspended container adjusted to a lever which yields a kymographic record; sedative effects of B, alone and in combination with pyramidone, somnifen, luminal and other agents are recorded. Boric acid suppresses strychnine convulsions, but caffeine stimulation was not prevented. G. H. S.

Intestinal peristalsis. VI. Physiological coördination of the movements of the longitudinal and circular muscles during peristalsis and the changes induced by physos-

tigmine. M. Baur. Pharmakol. Inst. Kiel. *Arch. exptl. Path. Pharm.* **131**, 233–54 (1928).—The coördination mechanism of peristalsis in the guinea-pig intestine is disturbed by physostigmine, which acts not directly upon the muscles but apparently through Auerbach's plexus. G. H. S.

Thiocyanogen as an agent for causing a fall in blood pressure. H. O. Behrens. Univ. Giessen. *Arch. exptl. Path. Pharm.* **131**, 255–61(1928).—Therapeutic expts. in man with KSCN or NaSCN are reported. In none of the 9 cases was the reduction in blood pressure sufficiently permanent to be of value G. H. S.

Concentration and action of narcotics upon the respiratory center. Elizabeth Csillag. Univ. Pécs. *Arch. exptl. Path. Pharm.* **131**, 279–88(1928).—The activity of the automatic respiratory center can never be diminished by const. concns. of narcotic without leading to a complete paralysis, *i. e.*, it behaves in accord with the all-or-none law of narcosis. G. H. S.

Quantitative study of the conductivity of nerves during narcosis. Anna Lánczos. Univ. Pécs. *Arch. exptl. Path. Pharm.* **131**, 297–304(1928).—Like irritability of the end app. of motor nerves, cond. conforms to the "all-or-none law of narcosis," differences in the behavior of the 2 phenomena being merely quant. G. H. S.

Mode of action of arsenic and related elements. VI. Action of hydrogen sulfide and hydrogen iodide salts on the frog muscle-nerve preparation. Richard Labes. Univ. Bonn. *Arch. exptl. Path. Pharm.* **131**, 305–21(1928); cf. *C. A.* **22**, 2411.—In many respects intoxication with H_2S resembles a simple suffocation, but differs in that treatment of the nerve-muscle prepn which has been exposed to H_2S with oxidizing agents leads to a further and irreversible injury, while treatment with a reducing agent leads to recovery. Furthermore, exposure of the H_2S-treated prepn to an abundance of O causes a loss in both direct and indirect irritability. With the muscle-nerve prepn. an oxidative NaI intoxication occurs, which is analogous to oxidative HI hemolysis, depending upon the formation of elementary I through the action of H_2O_2. **VII. Arsenic hydride hemolysis: An effect of colloidal arsenic.** *Ibid* 322–34.—In AsH_3 hemolysis the chief factor involved is the As derived through oxidation G. H. S.

Effect of local anesthetics on isolated blood vessels of the frog. Eduard Rentz. *Arch. exptl. Path. Pharm.* **131**, 357–66(1928).—As regards action in inducing vasodilatation, the anesthetics fall in the following order alypin (least active), novocaine, tutocaine, tropacocaine, eucaine B, cocaine, stovaine, psicaine (most active). Alypin and novocaine first cause vasoconstriction, then a vasodilatation which does not exceed the original condition. With tutocaine, tropacocaine, eucaine B and cocaine the vasoconstriction is followed by a dilatation beyond the normal state. With eucaine and cocaine the dilation appears earlier than with tutocaine and tropacocaine. Stovaine and psicaine are exclusively vasodilating, the reaction being within certain limits independent of the concn. G. H. S.

Comparison of the effects of cardiazole, coramine and scillaria upon vessels. K Fahrenkamp and H. Nocke. Univ Wien. *Arch exptl Path Pharm.* **131**, 367–75 (1928).—In a concn. of 1:100 cardiazole usually causes vasodilatation, while dilns. of 1:1000 cause constriction. When cardiazole 1:100 and 1:500,000 adrenaline are alternated the constricting effect of adrenaline is not manifested Successive treatments with cardiazole and strophanthin cause alternating constriction, thus, 1:1000 cardiazole constricts, 1:10,000 strophanthin dilates, 1:1000 cardiazole promptly constricts and 1:100 cardiazole dilates. With a constricting soln. (1:100,000) of strophanthin 1:1000 cradiazole causes vasodilatation. Vasodilatation is caused by 2.5% coramine, vasoconstriction by 0.25%. Following treatment with adrenaline 2.5% coramine always dilates, 0.25% constricts. The dilatation due to 1:100,000 strophanthin is replaced by constriction by 0.25% coramine, 1:100,000 and 1:200,000 solns. of scillaria cause vasoconstriction, 1:2 million and 1:20 million solns. dilate. G. H. S.

Localization of the sensitizing action of cocaine for the pupil. S. V. Anichkov and A. A. Sarubin. *Arch. exptl. Path. Pharm.* **131**, 378–82(1928).—Cocaine sensitization of the pupil for adrenaline only takes place when the sympathetic innervation is unimpaired. G. H. S.

Effect of adrenaline upon sugar mobilization in muscle. W. Grunke and A. Kairies. *Arch. exptl. Path. Pharm.* **133**, 63–8(1928).—In frogs the av. concn. of the perfusion fluid without added adrenaline was 0.164 mg. %, with adrenaline 0.360 mg. %. G. H. S.

Stimulation of the secretion of pituitrin by diuretics. H. Hoff and P. Wermer. Univ. Wien. *Arch. exptl. Path. Pharm.* **133**, 84–96(1928); cf. *C. A.* **22**, 638.—Dogs receiving diuretic agents such as euphyllin, novasurol and urea show a considerable increase in the secretion of pituitrin. Euphyllin injected intravenously into man exerts

a like effect. This response may be considered as a regulatory process to overcome impoverishment of the blood and tissues as regards water content. G. H. S.

Method of testing local anesthetics on sensory nerves of frogs. M. KOCHMANN AND H. BOEHMINGHAUS. Univ. Halle-Wittenberg. *Arch. exptl. Path. Pharm.* **133,** 121–8(1928).—A detailed description of the method of exposing the suitable nerves and applying the anesthetic. G. H. S.

Deposition of arsenic in the brain after application of neoarsphenamine, arsenious acid and arsenic acid. B. ENGELMANN. Univ. Berlin. *Arch. exptl. Path. Pharm.* **133,** 181–91(1928).—Repeated intravenous injections of neoarsphenamine, continued over a period of 2 weeks and involving a total of 120 mg. of As, resulted in no, or but slight, evidence of As deposition in the central nervous system of rabbits. With longer periods of treatment, the total dosage reaching some 300 mg. of As the brain revealed (av.) 0.04 mg. of As per 10 g. of brain substance. Higher values were found when the neoarsphenamine was injected in combination with sugar. A febrile state considerably increases the amt. of As to be deposited in the brain following intravenous injections of neoarsphenamine, a result apparently assocd. with the diminished As tolerance in fever. When neoarsphenamine is given during urethan narcosis the normal receptivity of the brain for As is reduced or abolished. Ether narcosis does not favor As deposition. Substances such as amyl nitrite, caffeine, and theophylline, which influence the blood vessels, do not increase the As transfer to brain tissue, nor does the brain seem to possess a greater tendency to acquire As because of a meningitis. When during a period of 5 to 6 weeks 25 mg. of As is given intravenously in the form of $NaAsO_2$, or 42 mg. as Na_2HAsO_4 not more than 0.02 mg. of As can be found per 10 g. of brain substance. Dogs which have received by mouth over a period of 5 ½ months a total of 3.6 g. of As_2O_3 show some 0.04 mg. of As per 10 g. of brain. G. H. S.

Local stimulating action of narcotics. ALEXANDER RIKL. Univ. Bonn. *Arch. exptl. Path. Pharm.* **133,** 192–201(1928).—A large series of narcotizing agents—alcs. and others—were tested upon the human eye and tongue for their local stimulating effect. In general their activity in this respect paralleled their narcotizing power. Of the substances tested phenol, camphor and menthol exerted the strongest local irritating effect. G. H. S.

Comparative study of the stimulating effect upon the respiratory center of some narcotics. WILHELM BLUME. Univ. Bonn. *Arch. exptl. Path. Pharm.* **133,** 202–26 (1928). Rabbits injected intravenously with aq. solns. of Et alc., heptyl alc. and ether give evidence of a stimulated respiratory center, an effect not manifested, or to but a slight degree, when $CHCl_3$ is injected. The most marked effects, in 2 kg. rabbits, were noted after the injection of 20 cc. of 5% Et alc., 20 cc. of 0.1% heptyl alc., or 20 cc. of 1% ether. When $CHCl_3$ is stimulating the effect is induced by 10–20 cc. of a 0.1% soln., and is not manifest until during the 2nd half hr. after the injection. Stimulation is not reflex in mechanism since it occurs when both vagi have been sectioned. The respiratory center impaired by morphine is stimulated by the same agents, but not by $CHCl_3$. G. H. S.

Effect of potassium tellurite upon phases of tissue respiration. RICHARD LABES. Univ. Bonn. *Arch. exptl. Path. Pharm.* **133,** 227–32(1928).—The capacity of minced muscle (guinea pig) to hydrogenate methylene blue with H activation is largely lost after treatment with K tellurite; but the same treatment does not impair the oxidation of *p*-phenylenediamine with O activation. G. H. S.

Effect of adrenaline upon the protein metabolism of isolated organs. B. S. SENTYURIN. Militär-Med. Akad., Leningrad. *Arch. exptl. Path. Pharm.* **133,** 233–41(1928).—When pure Ringer-Locke soln. is perfused through an organ (testis) for a long time the amt. of residual N present in the effluent gradually, but constantly, diminishes. The protein N diminishes also, during the first few hrs. of the perfusion but later increases. As a rule the amt. of protein N is greater than is the residual N, and as the perfusion continues this difference becomes greater. When adrenaline is perfused through the organ the amt. of residual N is increased, while the amt. of protein N in the effluent varies considerably, but usually the relation between protein N and residual N is altered, essentially through an increase in the latter. G. H. S.

Pharmacological study of sterols. HANS SEEL. Univ. Halle-Wittenberg. *Arch. exptl. Path. Pharm.* **133,** 129–80(1928).—Included in the study were α-cholesterol oxide, cholestantriol, cholestandionol, cholestendion, cholestandion, sitosterol, sitostantriol, oxycholesterol, oxysitosterol and β-cholesterol oxide. Upon the normal isolated frog heart all of these substances exert a stimulating effect, oxycholesterol being most active, but stimulation is most evident when the heart is fatigued and its action is impaired. With such hearts these substances frequently cause a complete restoration

of heart activity and a prolongation of its period of pulsation. β-Cholesterol oxide, oxycholesterol and oxysitosterol very definitely exert a detoxicating action upon hearts impaired by exposure to $BaCl_2$, $CuSO_4$, chloral hydrate, apomorphine, aconitine, apocholic acid and desoxycholic acid. In this action oxycholesterol and oxysitosterol are most effective. They are also detoxicating as regards the effects of thallium acetate, strychnine and camphor. Artificial irradiation has little, if any, effect upon the activity of the prepns. The stimulating effects are due primarily to sp. action on the heart muscle itself. With smooth muscle, such as the uterus, the sterols, particularly oxycholesterol and oxysitosterol, increase tonus and stimulate contraction. The sterols exhibit an antagonism toward adrenaline in its inhibitory effect upon uterine activity. Sterols have but little influence upon blood pressure, although in some instances a slight and transitory increase may be observed. Oxycholesterol stimulates metabolism and accelerates growth; O utilization is increased. Like irradiated cholesterol and cod-liver oil, non-irradiated oxycholesterol and oxysitosterol blacken photographic plates. When fed to rats only irradiated cholesterol exhibits antirachitic properties, and with the exception of oxycholesterol none of them has any effect upon xerophthalmia.
G. H. S.

Effect of some convulsion-producing poisons upon the blood sugar, the lactic acid and the alkali reserve. IJURO FUJII. Westf. Wilhelms-Univ. Münster i. W. *Arch. exptl. Path. Pharm.* **133**, 242–56(1928).—Picrotoxin and santonin cause an increase in both the sugar and lactic acid of the blood quite independently of the occurrence of convulsions, of effect upon the respiratory center or upon the body temp. The alk. reserve is reduced.
G. H. S.

The cerebral point of attack of α-lobeline. RUDOLF SCHOEN AND ERNST DERRA. Univ. Leipzig. *Arch. exptl. Path. Pharm.* **133**, 257–73(1928).—In its effect upon position and labyrinthine reflexes lobeline does not belong within the caffeine-camphor group. It causes convulsions in rabbits deprived of cerebrum but not in decerebrate animals. A characteristic respiratory arrest is induced and it is only with respect to respiration that lobeline is antagonistic toward morphine intoxication in both the intact and decerebrate animal. The cerebrum is not essential for the action of lobeline; the presence of the thalamus suffices to permit a complete picture of lobeline intoxication as seen in the normal animal
G. H. S.

Potential or phase effects of local anesthetics upon frog vessel preparations. ED. RENTZ AND C. AMSLER. Lettländischen Univ., Riga. *Arch. exptl. Path. Pharm.* **133**, 274–83(1928).—With alypine, novocaine, tutocaine, eucaine B and cocaine, prepns. of frog vessels reveal phase effects; stovaine and psicaine do not manifest like changes in activity.
G. H. S.

Effect of lobeline upon the circulatory apparatus. V. V. SAKUSSOV, JR. Militär-Med. Akad., Leningrad. *Arch. exptl. Path. Pharm.* **133**, 284–94(1928).—Lobeline exerts a vasoconstricting action through an effect upon the sympathetic system and through an indirect influence upon the adrenals. It stimulates the vagus center. Upon the isolated heart lobeline exerts a depressing effect, although with weak concns. an initial mild stimulation may be observed. It has no direct effect upon the walls of the vessels.
G. H. S.

Comparative study of the behavior of morphine rabbits intoxicated with morphine to pharmacologic agents which stimulate respiration. KONRAD SCHÜBEL AND WALTER GEHLEN. Univ. Erlangen. *Arch. exptl. Path. Pharm.* **133**, 295–316(1928).—Among the substances tested were lobeline, hexetone, cardiazole, camphogen, coramine and caffeine, the detns. involving the min. active dosage in mg. per kg. and the min. convulsion-producing dosage (from which are computed the therapeutic range and therapeutic index). Detns. were made for both intravenous and subcutaneous administrations.
G. H. S.

The alleged vasodilatation induced by high dilution of iodine salts. HERMANN FREUND AND WILLY KÖNIG. Westf. Wilhelms-Univ. Münster i. W. *Arch. exptl. Path. Pharm.* **133**, 317–24(1928).—The conclusions reached by Guggenheimer and Fisher to the effect that high dilns. of I salts cause vasodilatation and a reduced blood pressure could not be confirmed.
G. H. S.

Sugar content of whole blood in different vascular beds and its distribution between plasma and formed elements under normal conditions and after the administration of insulin and adrenaline as determined by the method of angiostomy in dogs. NINA KOCHNEV. *Arch. ges. Physiol.* (*Pflüger's*) **219**, 407–10(1928).—The hypoglucemia due to insulin is due to a diminished production of sugar by the liver and to a relative increase in sugar in the organs. Adrenaline hyperglucemia depends exclusively upon an increased sugar mobilization in the liver. During absorption from the intestine rela-

tively more sugar is taken up by the blood corpuscles than in hepatogenic sugar mobilization during fasting, in adrenaline hyperglucemia or in insulin hypoglucemia. In the fasting state only in muscle is the transfer of sugar about the same for both plasma and cells; in the spleen there is no transfer, and in all other organs the plasma is more involved than are the blood corpuscles. During alimentary hyperglucemia the kidney holds back more sugar of cellular origin than plasma sugar. Neither insulin nor adrenaline has any outspoken effect on the distribution quotients of the sugar excreted by the liver, although both of these substances are very important as regards the sugar of the blood and tissues. Under the action of insulin not only is the sugar relationship of the red cells and tissues changed, but a portion of the plasma sugar passes into the blood cells. Adrenaline acts differently in different organs as regards the distribution of sugar between plasma and tissue. G. H. S.

Effect of extreme dilutions of active substances on organisms. HERMANN JUNKER. *Arch. ges. Physiol.* (*Pflüger's*) **219**, 647–72(1928).—The expts. involve the effect upon paramecia of extreme dilns. (up to 1.10^{27}) of atropine, caffeine, the juices of orange and lemon, cocaine sulfate, Na desoxycholate, K oleate, octyl alc., AcOH, HCl, NaCl, $MgSO_4$, $CuSO_4$, urea, and rubio (a vitamin prepn.). G. H. S.

Fat and lipoid in the blood. IV. Distribution of fat and lipoid in the blood and the injection of insulin into dogs with pancreatic diabetes. MASAYOSHI MORIMOTO. Osaka. *Arch. ges. Physiol* (*Pflüger's*) **219**, 733–7(1928).—The concns. of fat and lipoid in the blood increase after complete removal of the pancreas. An injection of insulin promptly disposes of the increased fat in the blood. In hirudinized dog blood the corpuscles contain 156 mg. % (av.) of cholesterol and 395 mg. % total fat and lipoid, these values not being altered by pancreatogenic hyperlipemia or insulin treatment, although insulin has a marked effect upon the fat and lipoid content of plasma. G. H. S.

Potassium contraction in striated and smooth muscle. II. Permeability of muscle. ERNST GELLHORN. Univ. Halle a. S. *Arch. ges. Physiol.* (*Pflüger's*) **219**, 761–88(1928); cf. *C. A.* **21**, 2313.—In striated frog muscle K constriction is favored by the alk. chlorides in the series Li < Na, Cs < NH_4 < Rb, and inhibited by the alk. earth Ca, Sr, Ba and Mg, and somewhat more strongly by the chlorides of the heavy metals Co, Cd and Fe. Within the limits 6.1–7.7 K contraction increases with increased p_H. It is strengthened by hypotonic, weakened by hypertonic solns. As contraction augments the latent period is shortened. Anions favor the contraction according to the series Cl < Br, NO_3 < SO_4 < I < SCN. After exposure to different Na salts, Cl < I < SCN, KCl contraction is increased. With smooth muscle the alk. chlorides are stimulating as regards K contraction, in the series Li < Na < Cs < Rb. Mg and Ba change the tonus in such low concns. that their effect cannot be detd., but Ca and Sr are inhibitory, as are Co, Cu, Cd, and Fe. Increasing osmotic pressure and p_H reduce K contraction, and anions favor contraction in the order SO_4 < Cl < Br < I < SCN. Apparently both striated and unstriated muscle react to osmotic pressure and ionic concn. in the same way as regards K contraction, suggesting that in both, contraction is governed by the same physico-chem. processes. The effectiveness of osmotic pressure and ionic concn. is due to their effects upon permeability. G. H. S.

Effect of atropine on frog muscle. M. R. FRANCILLON. Physiol. Inst. Zürich. *Arch ges. Physiol.* (*Pflüger's*) **219**, 789–94(1928).—With rhythmic stimulation the summation capacity of atropinized muscle is lower than is that of normal muscle; to cause a complete tetanic contraction stronger and more frequent stimuli are necessary. The threshold of atropinized muscle is higher than that of normal muscle, and to weak stimuli atropinized muscle responds less vigorously. G. H. S.

Physiological action of 2-furancarbinol. M. OKUBO. Medical College, So. Manchuria. *J. Pharm. Soc. Japan* No. **539**, 39–44(1927).—The physiol. action of 2-furancarbinol is in most cases inhibitory and paralytic. Its dil. soln. paralyzes the sensory nerves. This suggests that it has an anesthetic action. In general, it resembles benzyl alcohol and represents an example where the physiol. action of an org. compd. depends greatly upon the side chain rather than upon the nucleus. N. U.

An experiment in toxicology: Antimony. J. WILSON DOUGAL. *Pharm. J.* **120**, 215–6, 225–6; *Chemist and Druggist* **108**, 353–4(1928).—Chem. analysis of a piece of *fur* which had caused *dermatitis* in wearing it (cf. *C. A.* **19**, 1199) at first gave indefinite results. However, when living *tadpoles* were employed in a systematic test for the toxicity of H_2O used in extg. the fur, a toxic effect was clearly noted, proportional to the amt. of fur used. The poison proved to be Sb, present in the ratio of 1:1000 parts of fur, added probably in the form of the mordant *tartar emetic*. The times required

to kill tadpoles in aq. solns. of tartar emetic of decreasing concns. were detd.; it appears that a 1:50000 soln. of Sb may be tolerated by these organisms. A 1:1000 aq. soln. rubbed on the skin causes smarting after 2 min. and develops a rash in 24 hrs.
S. WALDBOTT

Quanidine derivatives which lower the blood sugar. TAIZO KUMAGAI, SIN-ITI KAWAI AND YOSHIO SHIKINAMI. Tohoku Univ. *Proc. Imp. Acad. (Japan)* **4,** 23–6 (1928).—A large no. of guanidine derivs. have been prepd. and their blood-sugar-lowering actions detd. when administered to rabbits by mouth or subcutaneously. The action is exerted particularly by the polymethylenediguanidines. The following compds. have been prepd. by the condensation of the corresponding polymethylenediamines with ψ-thiourea in presence of HI; agmatine sulfate, m. 228°; tetramethylenediguanidine sulfate (not easily decompd. pure); pentamethylenediguanidine sulfate, decompd. 330°; hexamethylenediguanidine-HCl, m. 175–6.5°.
C. J. WEST

Toleration of the diuretic action of caffeine. GYOKUJO KIHARA. Tokyo Imperial Univ. *Proc. Imp. Acad. (Japan)* **4,** 418–20(1928).—Rabbits acquire a moderate degree of tolerance towards caffeine following upon repeated administration of gradually increasing doses of the drug. It requires approx. 4–6 months for the full development of toleration. The development of a decreased susceptibility to the diuretic action of caffeine is shown at first in the cessation of the extra-renal response and next in that of the renal response. But the renal vasodilatation to be seen immediately after the injection of caffeine appears in a caffeine-tolerant animal as well as in a control animal. An animal tolerant toward caffeine, theobromine and theophylline manifests a decreased susceptibility not only to the 1 but also to the other 2. In caffeine-tolerant rabbits, as in a control animal, no increase in the O consumption of the kidney is produced by caffeine injection.
C. J. WEST

The preventive action of metals against syphilis. C LEVADITI, V. S BAYARRI, R. SCHOEN AND Y. MANIN. *Ann. inst. Pasteur* **42,** 105–69(1928).—Rabbits were rendered resistant to subsequent exptl. infection with syphilis by the administration of finely divided Te, Bi, and certain derivs of the metals. The protection given by Bi may exceed that conferred by arsenobenzene and other arsenicals. The degree and duration of immunity depend both on the dose and on the nature of the metal deriv. administered.
ETHEL W. WICKWIRE

Emetine · its effect on the rabbit's heart. PHOEBUS BERMAN AND WM. H. LEAKE *California & Western Med.* **28,** 772–6(1928).—Emetine-HCl given intravenously to rabbits in doses of 1–2 mg./lb. of body wt. produces a distinct ventricular tachycardia. Normal rhythm returns in about 10 min. Digifolin even in very large doses produces no abnormal electrocardiogram Emetine-HCl digifolin combinations produce no definite changes unless the emetine is given in amts. equiv. to 2 mg. per lb. body wt. which is also the minimal lethal dose of the latter. Daily doses of 1 mg per lb body wt. produced no marked permanent changes in the electrocardiogram of rabbits receiving a total of 18 and 28 mg., resp.

R. A. GORTNER

The effect of certain electrolytes and nonelectrolytes on permeability of living cells to water. M. McCUTCHEON AND B. LUCKE. Univ. Penn. and Marine Biol. Lab., Woods Hole Mass. *J. Gen. Physiol.* **12,** 129–38(1928).—Permeability of the unfertilized eggs of the sea urchin (*Arbacia punctulata*) is greater in hypotonic solns of glucose, sucrose, and glycocoll than in sea water of the same osmotic pressure. The addn. to glucose soln. of small amts. of $CaCl_2$ or $MgCl_2$ restores the permeability to nearly that of sea water. The effect produced by $CaCl_2$ and $MgCl_2$ is antagonized by the addn. of NaCl or KCl. NaCl and KCl tend to increase the permeability of the cell to water, $CaCl_2$ and $MgCl_2$ to decrease it. A method for the quant. study of salt antagonism is given.
C. H. RICHARDSON

The digestion of oils by Amoeba dubia. J. A. DAWSON AND MORRIS BELKIN. Harvard Univ. *Proc. Soc. Exptl. Biol. Med.* **25,** 790–3(1928).—The protoplasm of *Amoeba dubia* has the ability to digest oils and therefore there is a lipolytic substance

present. Radiation with ultra-violet rays had a retarding effect on digestion of the irradiated oils, with the single exception of linseed oil. C. V. B.

Hook worm infection and popular anthelmintics. E. HASSLER. *Arch. Schiffs-Tropen Hyg.* **32**, 409–10(1928).—Review. FRANCES KRASNOW

Lactic acid and carbohydrate in sea urchin eggs under aerobic and anaerobic conditions. WM A. PERLZWEIG AND E. S. GUZMAN BARRON. Woods Hole Biol. Lab. and Johns Hopkins Univ. *J. Biol. Chem.* **79**, 19–26(1928).—Unfertilized eggs of *Arbacia punctulata* produce lactic acid under normal aerobic conditions. The amt. is notably increased under the anaerobic conditions produced by the addn. of KCN to sea water. There is also a slight increase after fertilization and in the early stages of cell division. With the eggs treated with KCN the greater concn. may be due to a retardation of oxidative processes; in the other instances the smaller increase might be due to an accelerated rate of oxidation causing loss of some of the lactic acid. The presence of free sugar and of glycogen could not be demonstrated but another investigator has reported the identification of glycogen in *Arbacia* eggs. Hydrolysis of the unfertilized eggs with acid yielded readily a fermentable reducing sugar from which an osazone was obtained. The anaerobic phase of metabolism of *Arbacia* eggs thus becomes quite analogous in its mechanism to that postulated for other tissues such as tumors, yeasts, etc. A. P. LOTHROP

Some physico-chemical phenomena in regeneration. I. Measurement of hydrogen-ion concentration in the regenerating extremities of the axolotl. N. OKUNEFF. Acad. Sci., Leningrad. *Biochem. Z.* **195**, 421–7(1928).—The continuous p_H detn. in the regenerating extremity of axolotls shows that there are 2 waves of increased acidity, one corresponding to the stage of wound healing, the other, to the stage of initiation of new cell proliferation. S. MORGULIS

The reaction of a natural protozoan community to some organic acids. DAGGMAR H. PETERSON. *Am. J. Hygiene* **8**, 741–56(1928).—The study was made of the protozoa in the liquid and sludge in Imhoff tanks of a sewage-disposal plant. The addn. of small quantities of lactic, acetic and butyric acids increased the no. of protozoa in a nutrient medium. Certain bacteria multiplied in the media to which these acids were added, and furnished food for the ciliates. The flagellates may have lived in a completely or partially sapropelic mode, and did not feed directly upon the bacteria. There was a critical concn. limit, where the percentage of acid in a nutrient medium became lethal to the protozoa. The lethal amt. appeared to vary for different species of protozoa. The p_H range between upper and lower lethal limits varied for different species of protozoa. *Euglena polymorphs* could subsist within a wider range of H-ion concn. than the other protozoa studied. L. W. RIGGS

Experiments on the automatic rhythm of heart strips of the soft-shelled turtle. I. Influence of the method of storage. HUNG-PIH CHU. Peking Union Med. Coll. *Chinese J. Physiol.* **2**, 285–92(1928).—Heart strips from freshly caught turtles (*Trionyx Sinensis*) react best. Turtles, kept 1 or 2 weeks by being buried in moist clay at a temp. between 22° and 24°, may be used. Market turtles give unreliable results. **II. Influence of the season.** *Ibid* 293–8.—When turtles in any season are exposed to different temps., the cooled animals behave like "winter" turtles, and the warmed animals like "summer" turtles. Winter or cooled turtle heart strips commence rhythmic activity immediately on immersion in 0.7% NaCl at 20°. The rate at first falls rapidly but after 1 hr. a slower rate is maintained without change until exhaustion of the muscle. Summer or warmed heart strips commence contractions only after being immersed for some time, but when rhythm begins it is maintained at a slow rate until the end. L. W. RIGGS

Nature of crystalloid formations contained in the "enigmatic vesicles" of Sipunculidae. A. DAMBOVICEANU. *Compt. rend. soc. biol.* **98**, 249–50(1928).—The substance in question forms on the filter during the filtration of the blood of *Sipunculus nudus*. After extn. in the Soxhlet app. with 95% alc. and repeated recrystns. the substance has the following properties: insol. in water, nearly insol. in cold alc., slightly sol. in acetone, readily sol. in $CHCl_3$, Et_2O, hot alc. and C_6H_6. It crystallizes from

hot alc. in needles, m. 50–55°, on recrystn. m. 40–45°. It does not give reactions for cholesterol, choline or P, and is probably a mixt. of aliphatic acids or salts of these acids.
L. W. Riggs

The loss of weight of Tenebrio molitor L. at the time of death by starvation is independent of the temperature. Georges Teissier. *Compt. rend. soc. biol.* 99, 602–3 (1928). L. W. Riggs

Rate of oxygen absorption by certain marine fishes as affected by the oxygen content and carbon dioxide tension of the sea water. Edwin B. Powers and Lula M. Shipe. Univ. Tennessee. *Pub. Puget Sound Biol. Sta.* 5, 365–72(1928).—The rate of O absorption in cc. per kg. per hr. during the first 10 min. of exposure by the herring (*Clupea pallasi*), silver salmon (*Oncorhynchus kisutch*), and by the viviparous perch (*Cymatogaster aggregatus*) is lowered by a decrease in the O content or by an increase in the CO_2 tension of the sea water in the order named. A combination of these factors is more effective than either one alone. The data indicate that the herring is more sensitive to an increase in the CO_2 tension of the sea water, and the silver salmon is more sensitive to a decrease in the O content of the sea water. The viviparous perch is more resistant to changes in these 2 factors than either of the other 2 fishes. This is in keeping with the fact that the alkali reserve of the blood plasma of the viviparous perch changes very rapidly with change in the CO_2 tension of the sea water. L. W. R.

Seat of elimination of urinary constituents in the toad's kidney. I. Inorganic substances. Kenzo Tamura, Otohiko Hayashi, Taiira Fujita and Yu Ting Shah. Tokyo Imp. Univ. *Proc. Imp. Acad (Japan)* 4, 410–2(1928).—Chloride is eliminated practically only through the glomeruli, while all the other inorg. constituents (K, Ca, Mg, SO_4 and PO_4) are eliminated from both the glomeruli and the tubules. **II. Organic substances.** K. Tamura, Fusao Fukuda, Gyokujo Kihara, T. Fujita and Seizo Komatsubara. *Ibid* 413–4.—Such org. constituents as urea and uric acid are eliminated partly from the tubules but mainly from the glomeruli. The glomerular filtrate is concd. into the urine, not only by reabsorption of fluid in the tubules but by elimination from them of urinary substances. C. J. West

Chemical study of the waters of Argyle Lagoon (Blalock, *et al*) 14.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

A new constant for the analysis of butter fat and its substitutes. E. Tchétchéroff and N. Charliers. Lab. Intercommunal de Bruxelles. *Chimie et industrie* Special No., 832–3(April, 1928); cf. *C. A.* 22, 2676.—The method described by Kuhlman and Grossfeld (*C. A.* 20, 2373) is described, and the results obtained on a large no. of samples of butter fat are compared with those of the Kirschner and Leffmann-Beam methods. For detecting adulteration, it agrees fairly well with the Kirschner no. detn., but shows considerable divergence from the Leffmann-Beam no. It is easier and simpler to carry out than the Kirschner no. detn.; but has the serious drawbacks of necessitating a blank, which increases rapidly with the time of heating for sapon. A. P.-C.

Does the cooling of cream to a low temperature have a detrimental effect on the odor and flavor of butter? W. van Dam. *Vereenig. Exploitatie Proofzuivelboerderij Hoorn* 1926, 153–6; *Chem. Zentr.* 1927, II, 1106.—Comparative tests in which the cream was cooled for about 21 hrs. to a few degrees above 0° before souring showed no detrimental effect. J. S. Reichert

The lipolysis of worked butter several days after preparation. Otto Gratz. *World's Butter Review* 2, Nos. 7–8, 21–2(1928).—Bacteria develop most rapidly on the outer layer of the butter. In several expts. with mixed butters, it was found that there was a greater acid content when the outer layer was not removed. When the outer layer was removed before working the butter, the fat splitting in the inner part was not nearly so great in the same period of time. In these expts. the butter was stored 1–14 days before it was worked. The no. of lipolytic bacteria and the activity of their enzymes will decide the degree of fat-splitting that will occur. The highly lipolytic *Oidium lactis* and fat-splitting fungi ought to decide the issue here. As a rule the fat-splitting is not influenced to any degree during the first 14 days by mixing the outer and inner parts. After this period, however, it may have an effect in influencing lipolysis in some cases. If the outer and inner parts are mixed together, other component parts of the butter suffer change and decompn. and this, therefore, influences the taste and quality. J. C. Jurrjens

Margarine in the light of modern nutrition. F. DANNMEYER. *Volksernährung* **2**, 193–5; *Chem. Zentr.* **1927**, II, 1219.—A discussion concerning the absence of vitamins in margarine, and the possibility of adding vitamin D artificially. G. SCHWOCH

Difficulties in connection with the inspection of milk. ALFRED WEICH. *Oesterr. Chem.-Ztg.* **31**, 117–21(1928).—This pertains mostly to conditions in Austria. J. C. JURRJENS

Determination of the value of milk by quality. K. ZEILER, H. BAUER AND A. BERWIG. *Milchwirtschaft. Forsch.* **5**, 557–662(1928).—Data are given on the use of the following tests to det. the value of milk: sediment, condition of can, reductase test, fat content and acidity. GEORGE R. GREENBANK

Iodine content of milk powder. DON R. MATHIESON. Univ. of Minnesota. *Proc. Soc. Exptl. Biol. Med.* **25**, 826(1928).—Samples of powdered whole milk and of lactic acid milk from Indiana (goitrous region) were found to contain 166 and 44 parts of iodine per billion; these values may be compared with 62 parts per billion (dry basis) for milk from Berne, Switzerland (goitrous region) and 400 parts per billion for milk from the California coast where the feed was bathed by sea-spray (non-goitrous region). C. V. B.

Determination of dry gluten by the flask method. F. MARION. *Chimie et industrie* Special No., 824–5(April, 1928).—See *C. A.* **21**, 2339. A. PAPINEAU-COUTURE

New method for the volumetric determination of proteins in milk. AL. JONESCO-MATIU AND C. V. BORDEIANU. Univ. de Jassy. *Chimie et industrie* Special No., 826–30(April, 1928).—See *C. A.* **22**, 3463. A. PAPINEAU-COUTURE

The influence of different sugars on the flora of milk and cheese. WILHELM BAADE. *Milchwirtschaft. Forsch.* **5**, 375–405(1928).—The effects of dextrose, sucrose and lactose on the flora and products formed by the bacteria were studied. GEORGE R. GREENBANK

Cereals and the agricultural-chemical industries which depend upon them. FRANCESCO SCURTI. *Atti II congresso naz. chim. pura applicata* **1926**, 317–26.—A description, with special reference to the *alc.*, *beer*, *bread*, *starch*, *dextrin*, *glucose*, *corn oil* and *fodder industries*. Expts show that *rice husks* are composed of about 50% cellulose and 20% pentosans. Distn. with 30% H_2SO_4 yields about 4–5% *furfural*, 11% *AcOH* and 65% of a carbonaceous residue suitable for a fuel. With conversion of the cellulose into *EtOH* and the hemicellulose into furfural, rice husks should offer the means of a profitable industry. Though under ordinary conditions, cellulose has no nutritive value, this is only true when it is united chemically with hemicellulose. If cellulose is freed from its complexes, it becomes perfectly assimilable and can produce as much fat as can com. pure starch. Since *wood* is a product of the synthesis of cellulose complexes, it also offers a potential source of valuable products, particularly *sugars*. Expts. on the *hydrolysis of corn cobs* by dil. mineral acids and alkalies under different conditions of temp., pressure and concn. show that with acids under pressure, cellulose and hemicellulose are first formed, followed by further hydrolysis to sugars, including glucose, arabinose and xylose. Since *pure cellulose* is assimilated by animals, such treatment offers a means of producing a *fodder from wood*. Straw, grape vines and hemp stalks were also readily hydrolyzed to cellulose and sugars. This process has already been tried industrially, the products being *cellulose paste* and a *molasses*. C. C. DAVIS

Investigation of the relation between the quantity of milk and the fat content. WLODZIMIERZ SZCZEKIN-KROTOW. Landwirtschaftl. Hochschule, Warschau. *Roczniki Nauk Rolniczych I Lesnych* **15**, 494–501(1926); *Chem. Zentr.* **1927**, II, 2481.—The fat content of milk depends not only upon the quantity of milk, but also upon the state of lactation. Contents of 2.2–5.3% were found, the most frequent content being 3.3%. Milk with less than 3% fat cannot therefore without further investigation be regarded as adulterated. C. C. DAVIS

The calcia milk of Moll. FRITZ GERNSHEIM. *Münch. med. Wochschr.* **74**, 1184–6; *Chem. Zentr.* **1927**, II, 1410.—A description of the prepn. of a curative food from milk with the addition of Ca lactate for treating acute dyspepsia. The prepn. is not only as valuable as the original milk albumin of Finkelstein but excels in many respects. J. S. REICHERT

The origin of saltpeter rinds in cheese. F. W. J. BOEKHOUT, W. VAN DAM AND J. VAN BEYNUM. *Vereenig. Exploitatie Profzuivelboerderij Hoorn* **1926**, 1–14; *Chem. Zentr.* **1927**, II, 1106.—Characteristic, mostly brownish red to greenish yellow rinds, 0.25 to several cm. deep, ran parallel to the nitrite (produced by the added saltpeter) content. Bacteria which reduce nitrate to nitrite were isolated. By the action of

nitrite on casein N_2 and CO_2 are formed. The coloring matter in cheese showed no evident influence. J. S. Reichert

A simple method of ascertaining whether a flour answers the official requirements. Stefano Camilla. *Giorn. farm. chim.* **76**, 341–6(1927); cf. *C. A.* **22**, 3239.—With a 10% content in soy-bean flour the crumb of bread from 85% flour has a yellowish tint, that from 75% flour a brownish tint. Mary Jacobsen

Flour improvement without the use of chemicals by the method of D. W. Kent-Jones. J. Spousta. *Chem. obzor.* **3**, 230–1(1928).—The flour was heated in a sealed tin box to 82° for 10–12 hrs. and then added in various quantities (from 0.7 to 10%) to the original untreated flour. The baking tests carried out with these mixts. did not show (contrary to the results obtained by D. W. Kent-Jones) any improvement of pastry products and no increase in vol. was observed. Jaroslav Kučera

Flour bleaching. III. Process of Thomas-Humphries. J. Spousta. *Chem. obzor* **2**, 65–9; *Chem. Zentr.* **1927**, II, 988.—S. discusses the process of Thomas-Humphries, the feature of which is that certain metallic salts in an org. form (the compn. is not given) are sprayed into the flour. The results of baking tests are given (Czechoslovakia). The results are fluctuating and not always satisfactory. G. Schwoch

Flour bleaching. IV. J. Spousta. *Chem. obzor* **2**, 161–4; *Chem. Zentr.* **1927**, II, 988–9; cf. preceding abstr.—The Greffenius, the Dollinger and the Bleichster processes are used. All 3, however, are copies of Alsop's process. The flour bleached according to the 1st process was lighter in color than unbleached flour; other differences were not observed. The bleached flour has lost its so-called "wholesome appearance." A so-called sterilization is out of the question. As to the 2nd process, the color of the bleached flour was lighter, but the circumference of the pastry baked from it was smaller. G. Schwoch

The baking power of wheat flours and possibilities of its determination. E. Berliner and J. Koopmann. *Z. ges. Muhlenwesen* **4**, 119–25; *Chem. Zentr.* **1927**, II, 2785.—The ash of wheat is approx. 2%, of the lightest flour 0.3%, of bran 5%. The % compn. of the ash of wheat is P_2O_5 50, K_2O 30, MgO 10, CaO 5. With increase in the degree of milling the P_2O_5 increases most rapidly, the CaO least so. The components of the ash are apparently present in org. combination, with no prospect of partial enrichment by fertilization. The inorg. salts, chiefly phosphates, which are present in aq. solns. of flour and in dough originate from hydrolytic enzymic processes, and are of great importance in the behavior of leavened dough. Titration in steps is superior to simple acid titration for the electrolytic characterization of the flour. A good baking requires a sp. optimum p_H value of the dough, which is controlled by the character of the flour and of the baking and depends upon the buffer power. C. C. Davis

Iodine evaluation of grain flour. T. Chrzaszcz and W. Michalski. Poznan Univ. *Przemysl Chem.* **12**, 342–9(1928).—Exts. of rye and wheat flours absorb I_2 in a quantity dependent on the kind and content of sol. carbohydrates of the flour, especially the dextrins. The more dextrins of medium mol. wt. there are in the flour the more I_2 is absorbed. Since the dextrin content characterizes the degree of grinding, manner of preservation and ripeness, as well as conditions of reaping, the I_2 absorption of a flour gives a new basis for rapid evaluation of the properties of a flour and of its baking value. A. C. Zachlin

A comparative study of the glutelins of the cereal grains. Ralph K. Larmour. Univ. Minnesota. *J. Agr. Research* **35**, 1091–1120(1927).—Alkali-sol. proteins were prepd. from such cereal grains as wheat, rice, corn, oats, einkorn, emmer, durum wheat, teosinte, rye and barley. Analyses for N distribution by the Van Slyke method revealed a well-marked relationship between the various prepns., especially in respect to the basic N fraction. Glutenin of wheat and oryzanin of rice, both well-defined glutelins, occupy positions at the extreme opposite limits of the class in respect to ammonia N and total basic N, and the corresponding values for the other proteins described fall within these limits. This is submitted as evidence that the prepns. obtained belong to a definite class of proteins, the glutelins, which is represented in all the cereal grains thus far studied. A bibliography of 44 references is appended. W. H. Ross

Correlation of kernel texture, test weight per bushel and protein content of hard red spring wheat. J. H. Shollenberger and Corinne F. Kyle. U. S. Dept. Agr. *J. Agr. Research* **35**, 1137–51(1927).—Data from 1200 representative samples of hard red spring wheat were studied by gross, net and multiple linear correlation methods and by multiple curvilinear methods to det. the relationship of kernel texture, test wt. and protein content. A fairly strong tendency was noted for protein content to increase as the percentage of dark, hard and vitreous kernels increased. This relation was

curvilinear in character and was pronounced in the samples having a high percentage of dark, hard and vitreous kernels. A significant correlation was found between test wt. and protein content. The tendency was for protein to increase as the test wt. increased in wheats weighing less than 54 lbs., but in wheats weighing more than 54 lbs. the tendency was for protein to decrease as the test wt. increased. Forty-four % of the variation in protein was found to be due to the combined influence of these two grading factors. Kernel texture, however, was considerably more important than was test wt. A method is presented for estg. the protein content when the kernel texture and test wt. are known. No correlation was found between test wt. per bushel and kernel texture. W. H. Ross

Soluble carbohydrates in rye flours and evaluation of thickness of dough. T. Chrzaszcz and W. Michalski. Poznan Univ. *Przemysl Chem.* **12,** 389–402(1928).—Fresh normal flours are characterized by the approx. relationship of 1:1 between simple sugars (which reduce Fehling's soln. directly) and the complex sugars (which reduce Fehling's soln. only after inversion). During good storage this relationship may be shifted to 1:2 or even to 1:3. Poor damp storage causes an increase in sugar and decrease in dextrin content. The baking quality of flours was evaluated on equal working of the dough of const. consistency which was detd. with the aid of a cylinder 1 sq. cm. in cross section and weighing 90 g. suspended from the arm of a balance and submerged to 1 cm. in the dough. When uniformity of the flours was accomplished it was found that the dark flours gave better raising and yield of bread than the light flours. Effect of storage proved to be better on the dark than on the light flours. A. C. Zachlin

Seed kernels of Pinus pinea L. Angelos D. Maranis. Univ. Athens. *Arch. Pharm* **266,** 121–2(1928).—Examn. of the kernels was undertaken in order to det. their food value, the prevailing popular opinion being that they are very nutritious. Their most important constituents are: H_2O 4.88, ash 1.20, oil (extn. by CS_2) 51.50, N substances 37.45, carbohydrate 4.80%. The yellowish oil consisted principally of liquid acids (oleic) 95%, and solid acids (stearic) 5%. The following consts. were detd.: d_{15} 0.92134, solidification pt. $-21°$, n_D^{40} (Zeiss) 61, acid no. 4.19, sapon. no. (Köttstorfer) 192.22, I no. 119, Hehner no. 96, Reichert-Meissl no. 0.22, Polenske no. 0.35, ester no. 188.03. W. O. E.

The stable soy meal, a future human food H. Wastl. *Chem. Rundschau Mitteleuropa Balkan* **4,** 93–6; *Chem Zentr.* **1927,** II, 1105.—Reference is made to the high nutritive value of soy meal stabilized in a particular manner. J. S. R.

Purine bases in soy beans and flour. V. Ducceschi. *Arch. sci. biol.* (Italy) **12,** 181–4(1928).—The probability that the soy bean will play an important part in the national alimentation of Italy, led D to det. quantitatively the total purine bases in the seed and flour. Using the Kruger and Schittenhelm method he found: soy bean undried contains 0.173 and dried 0.191% purine bases; in defatted but undried flour 0.205% and in defatted and dried flour 0.233%. In spite of the high proportion of protein substances present in soy beans, the purine content is only slightly higher than that of other leguminous seeds. Peter Masucci

In what way does the quantity of sodium chloride influence the fermentation of dough when pressed yeast is used and when bottom beer yeast is used? Staiger and M. Glaubitz. *Brennerei-Ztg.* **44,** 150; *Chem. Zentr.* **1927,** II, 2019–20.—As the concn. of the NaCl increases, its influence upon both kinds of yeast becomes unfavorable. With pressed yeast an appreciably bad effect is evident only with a concn. of 3% or higher, and with beer yeast with a concn. of 2% or higher. Bottom beer yeast is useless in the baking industry. C. C. Davis

Natural and chemical leavening agents used in the baking process. Karl Schmorl. *Z. ges. Muhlenwesen* **4,** 74–6; *Chem. Zentr.* **1927,** II, 1313.—A discussion of employment and mode of action of yeasts; different kinds of natural yeast; fermentation; influence of temp., stimulants, and nutrients on the growth of yeast; examn. of yeasts; acid and alk. powders; mixing and differences in compn. of baking powders. G. S.

Baking yeasts from the factories of the Polish Republic. W. Iwanowski and J. Dembin. Polytech. Warsaw. *Przemysl Chem.* **12,** 349–67(1928).—This is a survey of the Polish yeast industry and a comparison of the yeasts of Polish manuf. with those of German manuf. There are 18 yeast factories in Poland with a potential capacity of about 25,000 tons yearly; 15 of these are active and produce about 7410 tons yearly. The rate of consumption of yeast is increasing. Chem. and biological tests are made on samples of yeast sent to a central testing lab. maintained by an assocn. of manufacturers. Numerous tables present the data. Polish yeasts are

found to last about 50 hrs.; time for raising dough 90 min. The German yeasts are reported to have 96–144 hrs. and 70–89 min. for corresponding values. A. C. Z.

Contributions to the analysis of cacao. PETER BERGELL AND LUDWIG FRESENIUS. *Z. med. Chem.* **5**, 61–2; *Chem. Zentr.* 1927, II, 1412.—In consideration of the observations of Rohrbach on the dietetic value of cacao deposits the authors recommend the investigation of the physical and chemical consts. of cacao since they have a bearing on its dietetic value. In the analysis of cacao the presence of decomposed cacao should be detd. This is best accomplished by detg. the p_H value on suspensions both in the cold and when hot. The total number of microscopic particles should be detd., the colloidal condition of a definite quantity of these particles should be studied, etc. J. S. REICHERT

The analysis of fruit and apple jams. ED. LASAUSSE. École de médecine, Nantes. *Ann. fals.* **21**, 346–7(1928).—Polemical with Muttelet (*C. A.* **21**, 3688; **22**, 828, 2012). A. PAPINEAU-COUTURE

The identification of artificial coloring matter in fruit juices and similar products. A. DE KROES AND A. RECLAIRE. *Chem. Weekblad* **25**, 525–8(1928); cf. *C. A.* **21**, 1852.—The usual reactions for coal-tar colors have been tried on a large no. of fruit juices. Most vegetable colors give a more or less colored thread after a single deposit on wool, but after a secondary treatment the chances of drawing a wrong conclusion are considerably less, although there are some vegetable colors that color wool after a secondary treatment. The AmOH test in ammoniacal soln. gives very good results, but experience has shown that several vegetable colors dissolve in AmOH. With the Caseneuve test, several vegetable colors give yellow filtrates instead of colorless ones. This test is suitable in cases in which both the AmOH test and the wool test of Spaeth lead nowhere, as for example with chlorophyll and Spanish pepper. Other methods of identifying coal-tar colors in fruit juices, etc., give results that are just as little reliable. J. C. JURRJENS

Utilization of the by-products of the cider industry. GASTON MALET. *Chimie et industrie* Special No., 781–4(April, 1928).—A discussion of and plea for the utilization of apple by-products. A. PAPINEAU-COUTURE

The problem of the use of lactic acid in the canning industry. HANNIS ECKART. *Konserven-Ind.* **14**, 457–9, 470–1; *Chem. Zentr.* 1927, II, 2360.—In ordinary concn. lactic acid has no bad corrosive action on Cu and Ni canning materials. For acidification it is not inferior to citric acid or to tartaric acid. C. C. DAVIS

Studies in home canning. I. Some factors affecting the keeping qualities of vegetables and meats canned by the hot water bath method. GERTRUDE SUNDERLIN, P. MABEL NELSON AND MAX LEVINE. Iowa State College. *Iowa State Coll. J. Sci.* **2**, 189–212(1928).—Spoilage records on 2732 pint cans of vegetables and meats are reported. The foodstuffs canned include: asparagus, beans, sweet corn, chard, tomatoes, beef and pork. The investigation included the effects of: previous history of foodstuff, precooking, delay in packing, duration of cooking, kinds of caps and rubbers, consistency of pack and storage. **II. Indices of spoilage in home canned foods.** *Ibid* 287–311.—The indices of spoilage on 615 jars of spoiled canned foods are presented. The criteria of spoilage include: (physical) appearance, odor, suction when seal is broken; (chemical) total acidity, p_H, and formol titration; and (bacteriological tests), microscopic examn., plate count at 37° and at 20° and growth in dextrose fermentation tubes. No one group of tests was conclusive but the physical evidences were most frequent indices of spoilage. It is best to use all three groups of tests. Change in odor was the best single test and formol titration and suction on breaking the seal ranked lowest. The paper includes 65 references and a brief digest of the literature since 1911 by years. F. E. BROWN

Are metal receptacles suitable for storing liquids in the beverage industry? ERICH WALTER. *Getränke-Ind.* 1927, 138–9; *Chem. Zentr.* 1927, II, 2124.—Expts. show that vessels made of Al, Fe, Zn, Sn and Cu are in principle unsuitable for storing or transporting beverages, since enough metal to affect the flavor is dissolved. Vessels made of V2A steel were without influence on the flavor. C. C. DAVIS

Preliminary conservation of fruit products without chemicals. H. SERGER. *Konserven Ind.* **14**, 469–70; *Chem. Zentr.* 1927, II, 2360.—Preliminary conservation may be obtained by sterilizing, by self-sterilizing of the material, or by chem. preservatives; the latter method is less desirable. After conservation in the so-called *Finckh* pots, vitamins A and C were still strongly present; B was much impaired, but not entirely destroyed. G. SCHWOCH

Urea in mushrooms. NICOLAI N. IVANOV. *Biochem. Z.* **192**, 36–40(1928); cf. **21**, 2018. S. MORGULIS

Nutritive value of mushrooms Cantharellus cibarius. J. Bareš. *Chem. Listy* **21**, 477–84(1927); cf. *C. A.* **22**, 254.—Mushrooms contain 9.58% of dry matter, of which 12.85% is ash and 3.50% is N, present partly as digestible protein, but to a large extent as chitin. Carbohydrates are present to the extent of 32.7%, chiefly as *d*-mannitol, sorbitol, dextrose, trehalose, cellulose and pentoses, other carbohydrates also being present. The nutritive value of mushrooms is small. B. C. A.

The toxicity of certain mushrooms. Chrétien and Leblois. *Rev. pathol. comp. hyg. gén.* **28**, 131(1928); *Bull. soc. hyg. aliment.* **16**, 253–4(1928).—Expts. were carried out on dogs. *Amanita muscaria, A. pantherina* and *spissa*, which had been dried at 38°, were found to be non-toxic. *A. citrina* which had been dried at 38° was slightly toxic when ingested in large quantities. Blanching with H_2O or with dil. AcOH destroyed the toxicity, and the H_2O or AcOH used for blanching showed no toxicity. *A. citrina* showed no toxicity after drying at 80°. *A. phalloides*, either raw or dried at 80°, is distinctly toxic; blanching in H_2O or in dil. AcOH removes the toxic principle, which passes into the blanching water but is destroyed when AcOH is used. A. P.-C.

Dry substance and starch content of potatoes by specific weight determination. Stan. Reynaert. *Natuurw. Tijdschrift* **10**, 117–24(1928).—Increasing sp. wt. of potatoes is accompanied by increasing dry substance, *i. e.*, mainly increasing starch content. Three practical household methods for agricultural use are described for detn. of the sp. wt. A table is added with sp. wt. as a function of dry matter and starch content. B. J. C. van der Hoeven

The action of phosphatide preparations. R. Rosenbusch and G. Reverey. *Margarine-Industrie* **1927**, No. 17: *Chem. Zentr.* **1927**, II, 2363.—A special device, is described in which in a reproducible way, the process of frying is imitated in a pan and the spurted fat collected on a coat of filter paper. Portions of 50 g. margarine were treated in the pan for 3 min. Margarine alone gave a loss through spurting of 4.95%, margarine contg. 0.1% *vitamargin*, a phosphatide prepn., lost only 0.46%. Contrary to Rewald, the alc.-insol part was found to be just as active as the alc.-sol. part. With 0.2% vitamargin, the spurting was practically eliminated. G. Schwoch

Rice. G. Issoglio. *Giorn. farm. chim.* **77**, 7–11, 33–42(1928).—Production, compn. nutritive value, vitamin content, the utilization of bran and polishings are discussed. In the province of Vercelli a bread with 5% rice flour is made which is equiv. to full grain bread. The utilization of rice bran made Italy fairly independent of the German supply of medicinal P compds. (phytin products). M. J.

The salmon of the Far East and its chemical examination. B. Pentegov, S. Georgievskii and U. Mentov. Univ. Vladivostok. *Labor. Allgem. Physik. Techn. Chem. Staatl. Univ. fernen Ostens* **1927**, 97–102; *Chem. Zentr.* **1927**, II, 2020–1.—Analyses of fresh salmon and of salmon salted in 3 different ways used in Russia and Japan are summarized. The I no. of the fat of the fresh salmon was 123, while the consts. of the fat from the salted fish varied greatly. C. C. Davis

Vinegar or lemon juice? M. Niermann. *Volksernährung* **2**, 260–2; *Chem. Zentr.* **1927**, II, 2126.—Lemon juice is not superior to vinegar in its acid properties, and in harmlessness they are the same. Lemon juice is, however, superior to vinegar as a source of vitamins and mineral substances. C. C. Davis

Industrial application of ozone in cold-storage plants. R. Capart. *Bull. assoc. élèves inst. sup. fermentations Gand* **29**, 369–73(1928).—Tests have shown that ventilation rapidly increases the no. of the bacteria through dispersion of the bacteria which brings them into more intimate contact with their food. Even when ventilation is practiced the bacteria are destroyed by O_3 at a rate which increases as the temp. falls (2 hrs. at 25°, 20 min. at 8°). The industrial application of these results in cold-storage plants is recommended and briefly discussed. A. Papineau-Couture

Present status of the molasses-feeds industry. M. Galland. *Chimie et industrie* **Special No.**, 821–3(April, 1928).—A brief review of recent progress and possible future progress of the industry. A. Papineau-Couture

Minerals in bovine feeding. H. H. Mitchell. Univ. of Ill. *J. Am. Vet. Med. Assoc.* **73**, 475–9(1928).—Discussion. Frances Krasnow

The vitamin content of silage fodder. Arthur Scheunert. Univ. Leipzig. *Z. Tierzüchtung Züchtungsbiol.* **8**, No. 3, 28 pp.; *Chem. Zentr.* **1927**, II, 2021.—An av. green silage fodder, prepd. according to the usual practice in Germany, contained vitamins A, B and C. Continued storage had an unfavorable effect on vitamin B. The vitamin C content of the stored fodder was lower than that of the fresh material. C. C. Davis

Industrial waste work of the sanitary district of Chicago [packing house waste] (MOHLMAN) **14**. *The toxicity of HCN (for rice weevil)* (ALLISON) **18**. The esterification of EtOH in citric acid *solution* (CORNWELL) **17**. *Lactic acid streptococcus* (DEMETER) **11C**. *I* as a biogenous element. XVI. The presence of I in feed (SCHARRER, SCHWAIBOLD) **11A**. Commercial caseins (FOUASSIER) **18**. *I* problem and exophthalmic goiter prophylaxis from the point of view of agricultural chemistry (SCHARRER) **11G**. Solubility of Cu in milk (SOLOMAN, QUAM) **2**. Shark liver oil (for use in food) (Brit. pat. 284,637) **27**. Apparatus for drying fruits or vegetables (U. S. pat. 1,686,500) **1**. Vertical column apparatus for drying grain (U. S. pat. 1,685,338) **1**. Apparatus for continuous mixing and delivery of "lard compound" (U. S. pat. 1,686,953) **1**. Apparatus for emulsifying milk powder, water and butter (Brit pat. 285,159) **1**. Removing incrustations formed from milk on hot metallic surfaces (Brit. pat. 284,778) **18**.

Food product. ISAIAH N ZELLER. U. S. 1,686,786, Oct. 9 A compressed mass is formed of layers of different kinds of dried fruits Each layer may be coated with chocolate or other coating.

Food product comprising pressed flakes of dried fruits. ISAIAH N. ZELLER. U. S. 1,686,785, Oct. 9.

Food fats. H. A. NEWTON. Brit. 284,368, Sept. 25, 1926. See U S. 1,601,229 (*C. A.* **20**, 3830).

Emulsified food. GLENN G. GRISWOLD. U. S. 1,686,556, Oct. 9. An emulsion is formed comprising honey 1 gal. and egg albumin 1 oz.

Flavoring material for foods. HERBERT T. LEO. U. S 1,686,670, Oct. 9. A non-hygroscopic flavoring is formed of cryst. dextrose together with natural fruit flavors such as fruit juices.

Soya-bean flour. GEORGE ALBERS. U. S. 1,684,654, Sept. 18. A flour proposed for use in preventing diabetes and also suitable for use as a substitute for casein as a glue is prepd. by comminuting soy-bean cake and drying to obtain a product contg. less than 10% moisture and fine enough to pass through a 72-mesh silk cloth.

Apparatus for applying cold air to flour during its milling or production. JEAN J. B. LOIZILLON. U. S. 1,687,300, Oct. 9. An app. is described in which material undergoing milling is subjected to currents of cold air, which produces a flour of improved quality for bread making.

Apparatus for pasteurizing milk in bulk. ERBY P. DAVIS, JAMES C. ROSS and MARTIN E. SMITH. U. S 1,686,227, Oct. 2.

Apparatus for deaerating milk. OLAF LARSEN (to The Creamery Package Mfg. Co.). U. S. 1,684,834, Sept. 18.

Drying milk. C KNOCH and F GROSS. Brit 285,313, July 21, 1927. Milk is evapd. *in vacuo* at a temp. below 60°, milk sugar and salts are sepd. by osmosis, the remaining concd liquid is transferred in the form of drops to steam-heated glass, china or like drums and the dried material thus formed is scraped off and compressed and may then be coated with the previously sepd. milk sugar and salts.

Milk preparation. GUSTAVE CHERBUIN-ROCHAT and ÉDOUARD JAUNIN. Fr. 635,798, June 11, 1927. Cream is sepd. from milk, the milk coagulated and the casein sepd., and sugar and the cream which has been sepd. are added. The cream and the casein-free liquid may be pasteurized.

Frozen egg product for food purposes. ALBERT K. EPSTEIN. U. S. 1,687,268, Oct. 9. Egg material is treated with an "edible acid" such as HOAc or citric acid to modify the viscosity of the material when frozen and to check decompn. after thawing. U. S. 1,687,269 specifies the addn. to egg yolk of salts such as NaCl or Na_2HPO_4 and an "edible acid" to give desirable viscosity and mobility after freezing and thawing. U. S. 1,687,270 specifies treating egg yolk with an "edible acid" such as H_3PO_4, HOAc, citric, tartaric, lactic or malic acid and with sucrose and NaCl to produce a product which when frozen and thawed has a viscosity less than if the sucrose and NaCl were not used.

Refining grain, meal and the like. ANTON S. POLLAK. Austrian 109,163, Nov. 15, 1927. The grain, etc., is treated with an atomized dil. soln. of H_2O_2.

Apparatus for drying cereals. SOCIÉTÉ D'EXPLOITATION DE BREVETS ET D'APPLICATIONS INDUSTRIELLES. Fr. 635,400, June 1, 1927.

Food from fish. A. EHRENREICH. Brit. 284,630, Feb. 1, 1927. The flesh of Plagiostomi and other marine fish is cooked with dil. HCl or other suitable dil. acid (suitably at 70–100°), free acid is neutralized with soda and the liquor is concd. *in vacuo* and may be dried.

Preventing blackening of canned fish foods. KOKICHI OSHIMA. U. S. 1,686,393, Oct. 2. Fish food to be canned is treated with a "regulating mixt." comprising NaCl together with a weak org. acid such as HOAc and a salt of such an acid, *e. g.*, NaOAc, to give a *p*H of 4–7 before canning and sterilizing.

Curing meat. EUGENE T. DRAKE (to Cudahay Packing Co.). U. S. 1,685,630, Sept. 25. A pickle for meat is prepd. by inoculating a series of cultures formed of an aq. soln. of a nitrate, sugar, salt and a protein material such as a meat-juice prepn. with bacilli or spirilli of non-putrefactive, non-pathogenic, nitrate-reducing, non-proteolytic, salt-tolerant character.

Gravies containing ingredients treated with ultra-violet rays. E. H. ERSLEV. Brit. 282,475, May 17, 1927.

Purifying pectin solutions. POMOSIN-WERKE GES. Brit. 284,273, Jan. 26, 1927. Substances producing turbidity in pectin solns. (such as starch decompn. products which resemble dextrin, albumins and the like) are removed by cooling the solns. (suitably below 0° somewhat for 3–4 hrs.) and sepg. the ppt. and ice formed.

Fruit juices. SOCIÉTÉ DES ÉTABLISSEMENTS BARBET. Fr. 32,711, July 8, 1926. Addn. to 615,942. A very high vacuum is employed in the evapg. tank to obtain concd grape or other fruit juices with sepn. of glucose by crystn.

Fruit and vegetable juices. FRED W. MANNING. U. S. 1,686,095, Oct. 2. Juices are expressed from apples, grapes or other fruits or vegetables through a body of treating solid such as kieselguhr, cotton fiber or asbestos continuously moved over a filter wall. An app. is described U. S. 1,686 096 specifies removing the juices from disintegrated fruits or vegetables in the absence of air. An app. is described.

Purifying fruit juices, wort, etc. MAX HAMBURG. Austrian 100,011, April 15, 1927. The juice or wort is treated with an oxidizing agent or with a weak elec. current, filtered, and then treated with a proteolytic enzyme.

Preservative coating on fruits and vegetables, etc. GEORGE W. BEADLE (to The Cellacote Co.). U. S. 1,685,392, Sept. 25. A homogeneous coating of hydrated cellulose is applied in liquid condition, *e. g.*, by use of a compn. prepd. from viscose, partially coagulated, *e. g.*, by $(NH_4)_2SO_4$ soln., and then further coagulated by treatment with acid; the coating is then treated with a substance such as NaOH soln. which will neutralize the acid and dried to cause the coating to shrink and exert pressure on the article which it surrounds. U. S. 1,685,393 relates to enclosing pineapples or other fruits or vegetables or eggs in a tight bag-like covering of material such as hydrated cellulose which is tightly fitted to the article in moist condition and then caused to contract on the coated article.

Beverages. J. A. FINLEY and C. P. WILSON (to Calif. Fruit Growers Exchange). Brit. 284,278, Jan. 27, 1927. Beverages are made by dilg. with water a mixt. of a colloid such as pectin, agar, gum tragacanth or gum arabic with fresh, dried, malted condensed or other milk and juices such as those of citrous fruits. The mixts. may be spray-desiccated.

Coffee extract. FRANK L. SLOCUM and WILLIAM E. TROUTMAN (to Magic Coffee Co.). U. S. 1,687,112, Oct. 9. Water is percolated through roasted ground coffee, successive fractions of percolate are collected, and these fractions are used successively to percolate a fresh portion of coffee. An app. is described.

Acid composition suitable for use in making foods or confections. HERBERT T. LEO U. S. 1,686,703, Oct. 9. A non-deliquescent compn. suitable for use in making jellies, jams, bakery products or confections comprises dextrose with which is incorporated a normally liquid acid or acid soln., *e. g.*, H_3PO_4, lactic acid, HOAc or malic acid.

Preparing spinach and like vegetables for canning. WILLIAM E. THOMAS. U. S. 1,685,511, Sept. 25. The vegetable is wilted at the max. temp. (suitably about 70°) at which the formation of pheophytin from the chlorophyll would be insufficient appreciably to affect the natural color of the vegetable.

Food for animals. A. EHRENREICH. Brit. 284,339, Jan. 28, 1927. Cuttings or bodies of sharks or the like, after removal of the skin, liver, fins and other parts otherwise utilizable, are pulped and desiccated *in vacuo* and ground.

Fodder and foodstuffs. EUGEN MISLIN (to Joseph F. Daubek and Georg Daubek.) U. S. 1,685,004, Sept. 18. See Brit. 254,388 (*C. A.* **21**, 2514).

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Our natural resources in present and future. F. M. JAEGER. *Chem. Weekblad* **25**, 482–91(1928).—A lecture, illustrated with graphs, of material and energy resources of the world. B. J. C. VAN DER HOEVEN

New chemical advances in Germany. W. JASTRZEBOWSKI. *Przemysl Chem.* **12**, 252–5(1928).—A review of industrial applications of new synthetic processes. A. C. ZACHLIN

Preparation for progress. GEORGE D. BEAL. *J. Am. Pharm. Assocn.* **17**, 730–6 (1928).—An address. The value of chemical and pharmaceutical research to industrial progress is emphasized. Many specific examples are given. L. E. WARREN

By-products of chemical warfare. AMOS A. FRIES. *Ind. Eng. Chem.* **20**, 1079–84 (1928).—A brief outline of some peace-time achievements of the Chem. Warfare Service. Among others, they involve: protection of marine piling, combating the boll weevil, the development of suitable ship-bottom paints, safe fumigation, and the development of simple masks for public health service and for protection against industrial poisoning and against NH_3. W. H. BOYNTON

The W. Gibbs triangle and its use in technical calculations. R. LITVINOV. *J. Chem. Ind.* (Russia) **4**, 291–3; *Chem. Zentr.* **1927**, II, 2091.—A graphical method is described which allows the *prepn. of any desired mixt. from several other mixts.* C. C. DAVIS

Economic symposium on nitrogen. Introduction. WILLIAMS HAYNES. *Ind. Eng. Chem.* **20**, 1128(1928). **The new economic aspects of nitrogen.** JASPER E. CRANE. Lazote Inc. Co. *Ibid* 1128–30. **Synthetic ammonia.** E. M. ALLEN. Mathieson Alkali Works, Inc. *Ibid.* 1131–3. **Economic relationships between nitrogen and fertilizers.** H. R. BATES. Intern. Agr. Corp. *Ibid* 1133–9. **Economic status of the by-product coking industry with reference to the nitrogen situation.** C. J. RAMSBURG. Koppers Co. *Ibid* 1139–44. **The international nitrogen problem.** W. S. LANDIS. Am. Cyanamid Co. *Ibid* 1144–7. E. J. C.

What a pound of ammonia will do. A. G. SOLOMON. *Power* **68**, 439–40(1928).—A table shows values from —10° to 85° F. of *pressure* in lbs. per sq. in.; *vol.* as cu. ft. per lb.; *vapor density* as lbs. per cu. ft.; *heat content* of liquid and of vapor as B. t. u. per lb.; *latent heat* as B. t. u. per lb.; and *entropy* of liquid and of vapor as B. t. u. per lb. per ° F. D. B. DILL

The flash points of various organic solvents. DANIEL FLORENTIN. Lab. Municipal de Paris. *Ann. fals.* **21**, 345(1928).—The following values were found: ordinary MeOH —7° (750 mm. Hg), abs. EtOH —12° (750 mm.), 95% EtOH +11° (748 mm.), PrOH 21° (752 mm.), BuOH 40° (740 mm.), fermentation BuOH 32.5° (740), AmOH 46° (740), Me formate —12° (765), AcOMe —11° (750), AcOEt —3° (765), com. AcOAm 32° (750); iso-BuOAc 22° (749), spirits of turpentine (from the Landes) 38° (751), benzine —8° (751), Me_2CO —20° (751), white spirit (150–200°) 39° (758). Detns. were carried out in the Luchaire app. A. PAPINEAU-COUTURE

Modern industrial evaporation methods. ERNST BLAU. *Chem.-Ztg.* **52**, 561–2 (1928).—The heat efficiency of single-stage or multi-stage vacuum evaporators is comparatively low. A great improvement is effected by compressing the vapors from the first evaporator, so that the condensation temp. of the compressed vapors rises above the boiling temp. of the liquid to be evapd. Best results are obtained, if this pressure evapn. by turbo and steam jet compressors is combined with multi-stage evapn.; little cooling water is needed. II. *Ibid* 578–9.—The compression-evaporation method is well suited for the evapn. of org. and inorg. liquids such as milk, sugar solns., soda and potash liquors, etc.; 15–25 kg. of water is evapd. per kw.-hr. and 10–30 kg. for very acid solns. Of increasing importance is the production of distilled water, as potable water, for industrial uses and for high-pressure boilers. Multi-stage evaporators, steam-jet compressors, electric and steam turbo compressors are in use. In the production of distilled water, independent of heat power plant, the price of the current and coal is largely the determining factor for the method to be employed. The use of electric turbo condensers in the evapn. of salt water is of great advantage, especially if the dissolved salts are recovered. Multi-stage evaporators and plants with jet compressors are cheaper in construction than compression-evapn. plants; the latter, however, being more economical, compete successfully. R. D. B.

Principles for studying rectification of liquid mixtures. CZESLAW GRABOWSKI. Polytech., Warsaw. *Przemysl Chem.* **11**, 253–9(1927).—By using as an example a mixt.

of C_6H_6 and $C_6H_5CH_3$ equations are derived for detg. the compn. of the liquid rectified and left in the tank after a given run. Equations for heat exchange are given, and a graphical method of interpretation is presented. Cf. *C. A.* **21**, 3402. A. C. Z.

The acceleration of sedimentation from suspensions. J. Traube. *Metall u. Erz.* **24**, 497–8; *Chem. Zentr.* **1927**, II, 2698.—By the addn. of small quantities of "Sedax," a colloidal reagent, it is possible to bring about in a short time the clarification of the liquor. The clarifying agent (0.1% soln.) is added at the rate of 80–100 cc. per hr. C. C. Davis

Technical sedimentation analysis. III. F.-V. v. Hahn and Aug. F. Thölcke. *Kolloid Z.* **46**, 44–52(1928); cf. *C. A.* **17**, 1535.—The methods for the prepn. of ordinary materials before their analysis by sedimentation are examd. critically. In the sedimentation analysis of the polishing materials of tooth paste, the situation is complicated by the fact that particle sizes vary from 40μ to mol. The suspensoid properties of the tooth paste in distd. water were comparable to the surface tension effect of the paste. A uniform method of prepn. of the pastes for analysis could not be developed. Most of the pastes suspended in soap solns. With some a Soxhlet extn. with alc. followed by suspension in water was effective. With others a combination of the treatments was satisfactory. L. F. Marek

The adsorptive properties of filter aids. H. L. Olin, N. A. Skow and Louis Zapf. *Trans. Am. Inst. Chem. Eng.* **20**, 251–72(1927); cf. *C. A.* **21**, 3691.—Evidence is presented to show that various substances used as filter aids in clarifying and filtering colloidal solns. are adsorptive agents acting preferentially on colloidal particles of given kind. It is suggested, therefore, that effective filtration of colloids is dependent upon the presence of adsorptive substances in the slurry rather than upon the formation of a net or screen to remove the particles mechanically. H. L. Olin

Effect of pressure on fundamental filtration equation when solids are non-rigid or deformable. D. R. Sperry. *Ind. Eng. Chem.* **20**, 892–5(1928).—In previous papers (*C. A.* **11**, 2945; **16**, 130) S. derived expressions for pressure-filtration which reduced to $WP = (Q_1^2 - R_qQ^2)/(T_1 - R_qT)$, where $W = 2K/R\%$ (K = rate of deposition, R = resistance of solids to flow, and $\%$ = percent of solids in mixt.), P = pressure (a const.), Q and T represent a point on a filtration time-discharge curve, Q_1 and T_1 represent another point on the same curve where $T_1 > T$, and $R_q = Q_1/Q$. By means of this expression an analysis can be made of a const.-pressure filtration time-discharge curve for the WP value, by merely knowing the time and discharge value of 2 points thereon and the pressure. To det. the exponent of P another curve is needed made under a different pressure, other conditions being held const. By means of a mechanical filtration recording device (*C. A.* **20**, 1477) consisting of (*a*) pressure-vessel with necessary valves, air gage and agitator, (*b*) filter cell with upper and lower horizontal filter leaves, and (*c*) a mechanical discharge recorder, time-discharge curves were obtained from a certain mixt. for several different pressures. The WP value for each curve was computed from the above fundamental equation. If the solid were rigid and undeformable the curve from the WP values for each pressure (plotted on logarithmic paper) would be a straight line making an angle of 45° with the pressure coordinate, corresponding to an exponent of unity for P. If the solids are not rigid or are deformable the curve will be either a line that is not straight or one that makes an angle of less than 45°. If the line is not straight, then certain factors other than pressure enter into the proposition; but if the line is straight, the tangent of the angle which it makes with the pressure axis is equal to the exponent of P. The time-discharge curves, computation tables and logarithmic curves are given for tests carried out with 5 substances. For all substances studied the logarithmic curves for WP values are straight lines, their angles having tangents as follows: starch, 0.87; kieselguhr, 0.82; red color, 0.7; mason's lime, 0.525; and fuller's earth, 0.115. The fundamental filtration equation then becomes, in its approx. form, $Q = A\sqrt{WP^cT}$ (for const. pressure conditions) or $Q = P^cW/2M$ (for const. rate of flow conditions), where A = tangent of substance concerned (see above), c = exponent of P, and M = const. rate of flow. The computation of the WP value from a time-discharge curve can be made in 15 min., by using the fundamental filtration equation at first cited above, and the accuracy of the computation is that of a 20-in. slide rule. Attention is called to the varying effect of pressure in filtering different substances; *e. g.*, by increasing pressure 4-fold with fuller's earth, the gain in output was 11%, while with kieselguhr it was 244%. W. C. Ebaugh

A new fireproof process, for the recovery of volatile substances. Weissenberger. *Feuerschutz* **7**, 258–60; *Chem. Zentr.* **1927**, II, 2091.—An *app.* and other equipment are described which permit the recovery of volatile substances and solvents according

to the process of the firm of Cheminova, Berlin. The process depends upon the fact that superheated absorption liquids show with the corresponding volatile substances so great a lowering of the vapor pressure that ignition of the vapor no longer occurs. C. C. Davis

Even and continuous delivery of liquids and gases for semi-plant work. M. Grochowski. Polytech., Warsaw. *Przemysl Chem.* **12**, 402-6(1928).—The liquid in question is forced dropwise through a siphon immersed in one neck of a Wolff bottle from which it is forced by air pressure produced by water entering another bottle which is only partly filled. Regulated rate of inflow of water into this last bottle dets. the rate of delivery of the liquid under investigation. To deliver gas continuously at a desired low pressure it is driven together with the water from a suction pump into a large bottle in which the water level is maintained by an adjustable siphon overflow. The gas is continuously forced out of this bottle through a delivery tube. A. C. Z.

Flow of brine in pipes. Richard E. Gould and Marion I. Levy. Univ. Ill. Eng. Expt. Sta., *Bull.* **182**, 24 pp.(1928).—The Darcy formula for loss of head in the turbulent flow range in circular pipes is $h = f(4lv^2/d2g)$, where f is a friction factor which is a function of a ratio or modulus $dv\rho/\mu$, known as Reynold's no., where d = inside diam. in ft., v = av. fluid velocity in ft., sec., μ = abs viscosity and ρ = density in lbs./cu. ft. The object of this investigation was to det. the relation between f and Reynold's no. when com. $CaCl_2$ brine is circulated in standard wrought-iron pipe under conditions encountered in refrigeration practice. The exptl. line consisted of wrought-iron pipe 1.38 in. in diam. with return bend, 108 ft equiv. length. Tests were made with variation of d. and temp. of soln. and velocity of flow and measurements were made of corresponding pressure drops. On plotting log friction factors as ordinates against log Reynold's no. as abscissas a curve was obtained slightly lower than the mean curve established by other investigators for flow of air, steam, water and oil in clean steel and cast-iron pipes but parallel with it. H. L. Olin

Dehumidification of air. C. S. Keevil and W. K. Lewis. *Ind. Eng. Chem.* **20**, 1058-60(1928).—A brief discussion of partial dehumidification of unsatd. air by water-cooling, without first bringing the air to the satn. point. Emphasis is placed on the relations and their significance of the diffusion of both heat and vapor through the gas film on the surface. A diagrammatic and a mathematical representation are indicated. Exptl. data confirm the representations in the cases of low humidity and work is being done with conditions of high humidity, when computation methods become more involved. W. H. Boynton

Determination of moisture in steam by electrical conductivity. M. E. Fitze. Milwaukee Elec. Railway and Light Co. *Power* **68**, 484-5(1928).—It is assumed that entrained moisture in steam carries solids in the same proportion as boiler water. A calibration curve is obtained by collecting 2 l. of condensate, adding boiler water in increments of 2 cc., and detg. cond. with a Leeds and Northrup portable resistance meter using a portable dip cell. Cond. is plotted against % boiler water added. A second curve, drawn through the origin and parallel to the first shows the direct relation between moisture of the steam and cond. of the condensate. D. B. Dill

Mode of operation of steam and fire cooking in liquid containers. W. Redenbacher and J. Huber. *Arch. Wärmewirt.* **7**, 103-6(1926).—Some tests on over-all heat transfer rates were made on the cooling of mash and of *worts* of different strengths with water. For a 12.5% wort the rates are about 15% less than for pure water, while for 50% wort the rates are about 25% of those for 12.5% wort. Mash lies about half way between pure water and 50% wort. Ernest W. Thiele

Regularities in the technical plasticization of machined and molded materials. Otto Manfred and Josef Obrist. Physik. Inst. Techn. Hochschule Brunn. *Z. angew. Chem.* **41**, 971-7(1928); cf. *C. A.* **22**, 173.—A continuation of work on plastics and synthetic resins, in which the elastic properties of the materials are studied. The results confirm those previously published. J. H. Perry

The Ruths accumulator in chemical works. K. Schiebl. *Arch. Wärmewirt.* **8**, 379-83(1927).—Flow diagrams are given, showing the ways in which an accumulator was included in various steam systems, especially in *sugar works*. E. W. T.

Results obtained with a Ruths accumulator in a textile plant. H. Severin and Fr. Scupin. *Arch. Wärmewirt.* **8**, 369-74(1927).—A description of plant conditions before and after installation of the accumulator, which greatly increased production. Ernest W. Thiele

The technic of producing highly dispersed solids in ball mills. K. Bergl and J. Reitstötter. *Kolloid-Z.* **46**, No. 1, 53-5(1928).—Dispersion methods have superseded condensation methods in the production of colloids. Some of the proposed

dispersion methods are reviewed and emphasis is placed on the ball-mill method. An analysis is made of the mechanism of ball-mill grinding. Volatile, org. liquids may be used as dispersion media without danger of explosion, but the mechanism must be understood in order to regulate the speed properly to prevent free falling of the balls.

L. F. MAREK

Possible working substances for steam power plants. A. LOSCHGE. *Arch. Wärmewirt.* **9,** 75–9(1928).—The thermodynamic properties of H_2O, Ph_2O and Hg are examd. as to their suitability for practical working cycles between 450° and 20°. The theoretical advantages of Ph_2O are too small to outweigh the practical difficulties, but the Hg-H_2O combination is promising. ERNEST W. THIELE

Calculation of the most economical thickness of insulation. E. BORSCHKE. *Arch. Wärmewirt.* **9,** 117–20(1928).—A detailed mathematical discussion, including diagrams to aid in the solution of the equations arrived at. E. W. T.

The testing of insulators after pronounced fouling. HEINZ BECHDOLDT *Keram. Rund.* **36,** 241–3(1928).—For the simulation of fouling in use of high-tension insulators by rain-water, fog, salt spray, chem. ppts. and dusts a room was constructed in which insulators could be placed connected with high-voltage currents and observed through windows. Water and solns. of various salts, alkalies and acids were sprayed into the room. Deposits of metallic dusts gave a flash-over voltage of 3–4% of the normal value, salt deposits 10% of the normal value, soot and S 10–15%. Cement dust caused a flash-over at 20% of the normal voltage and street dusts about 80%. The shape of the insulator affected the results considerably. H. INSLEY

Observations on the properties of certain so-called thermal insulators. JOHN B. DUTCHER. Indiana Univ. *Proc. Indiana Acad. Sci.* **37,** 227–31(1927).—Two warm vessels, one covered with a single layer of asbestos paper and the other uncovered, were allowed to cool and the usual cooling curves were obtained. It was found electrically that 24% more heat was required to maintain the covered vessel at 80° than the uncovered vessel, the room being at 27°, and water being in each vessel. With 2 similar pieces of stove pipe, one being covered with a single layer of asbestos paper, it was found electrically that it required nearly 45% more energy to maintain a temp. of 140° with the covered pipe than the naked pipe. Thus a *thin* layer of a poorly conducting material increases the loss of heat. The increase in radiation resulting from the change in the nature of the exposed surface thus outweighs the insulating effect. Hence the use of a *thin* layer of asbestos on the grounds of heat economy is deceiving. S. L. B. ETHERTON

Systems of heating by superheated water. L. KLOTZ. *J. Chem. Ind. (Moscow)* **5,** 628–9(1928)—The system of heating employed in *Raschig's coal-tar distn. plants* presents many serious defects. The system is based on the principle that the lower sp. gr. of hot water will cause it to rise above the cold water and thus force the circulation of the former; as, however, the difference of sp. gr. between hot water and cold water is insignificant, the speed of circulation of hot water is very small and, on being still further reduced by the friction existing in the pipes (coil), the circulation is sometimes apt to cease altogether. Moreover, a special water superheater must be attached to every single distn. retort. The system of heating by means of the *circulation pump of Opitz and Klotz* is free from these defects. This pump forces the superheated water through the heating coil with comparatively great speed. As the heating effect depends on the rate of hot-water circulation, it is thus correspondingly increased. The speed of the superheated water being in the latter system independent of the temp., pipes and coils of any desired length can be used, and thus several retorts can be heated simultaneously by the use of the same pump. While the pump always remains cold, it may be used for heating with water superheated up to 400°.

BERNARD NELSON

Heat transfer in condensers. W. K. LEWIS. Mass. Inst. Tech. *Am. Gas J.* **128,** No. 3, 42–4(1928).—The cooling of gases contg. vapors which condense during the cooling process is considered. Steam-air mixts., of dew point of 180° F., were cooled to 220° F. with cooling water not higher than 120° F. at any place, and condensation of water was observed on the cooling pipes. Heat transfer coeffs. over 10 times the value which was expected were also observed. L. discusses this case theoretically and shows that the heat of condensation is not transmitted through the gas film on the pipes and should not be considered in calcg. the coeffs. The vapor passes through the film by diffusion and is condensed on the cold pipe surface. In calcg. the coeffs., however, the sensible heat of the condensed vapors must be considered as passing through the gas film and L. discussed the assumptions to be made here. Flow of oils in coolers and heaters is considered and the difference in power required

for pumping in both types is explained by the difference in viscosities of the hot and the cold films. M. C. ROGERS

Heat-transfer data for the scrubber designer. TED ROSEBAUGH. Pacific Gas and Elec. Co. *Chem. Met. Eng.* 35, 144–8(1928).—R. discusses the need for accurate data for designing gas scrubbers. Curves showing results of tests made on an exptl. plant under operating conditions are given. Water-satd. oil-gas of 550 B. t. u. was passed through 2 scrubbers, each packed with wooden grids. Data were taken for a wide range of conditions, and curves are presented which show the effect on the over-all heat transfer coeff. of (a) water rate, (b) gas velocity and (c) inlet gas temp. Other curves are given showing heat content of satd. oil-gas, crit. velocities of gas and air for various tray spacings, and such other data as are necessary for calcns. involved in scrubber design. M. C. ROGERS

The removal of hydrogen sulfide from industrial gases by means of alkaline ferricyanide. F. FISCHER AND P. DILTHEY. *Brennstoff-Chem.* 9, 122–6(1928).—Alk. solns. of $K_3Fe(CN)_6$ are tested for removal of H_2S as S from H_2 gas carrying known known amts. of H_2S. Factors detd. are: (a) effect of alk. concn. on S pptn. and amt. of $K_3Fe(CN)_6$ used in side reactions (formation of $K_2S_2O_3$, K_2SO_3 and K_2SO_4); (b) effect of alkali concn. and concn. of $K_3Fe(CN)_6$ on reaction velocity; (c) effect of concn. of the $K_4Fe(CN)_6$ formed on the efficiency of H_2S oxidation. The best removal of S (96.05%) was obtained with a 15% $K_3Fe(CN)_6$ soln. contg. 1 mole Na_2CO_3 × $^1/_3$ mole $NaHCO_3$ per mole $K_3Fe(CN)_6$. The S pptd. was 0.3135 g., requiring 6.450 g. $K_3Fe(CN)_6$, 3.95% of which was used in side reactions. Stronger Na_2CO_3 or added KOH increases the amt. of reagent used in side reactions. Concn. of $K_3Fe(CN)_6$ has no influence on its efficient utilization, but an enormous influence on reaction velocity. The S obtained is very pure. Electrolytic regeneration of the $K_3Fe(CN)_6$ soln. seems practical. For this purpose 3 kw.-hrs. should be required per kg. S produced. J. D. DAVIS

The use of dry chemical fire extinguishers in industrial plants from the standpoint of their effect on the user. W. ELSNER V. GRONOW. *Zentr. Gewerbehyg. Unfallverhüt.* 14, 161–6; *Chem. Zentr.* 1927, II, 723.—With proper use there is no danger to the health or safety of the user. CCl_4 can form $COCl_2$ with alc., wood fiber and Fe but is safe for garages, railroad trains, rubber and extn. plants. *Methyl bromide* and "saponin" extinguishers can at the most cause slight injury to health. J. S. REICHERT

Benzene poisoning as a possible hazard in chemical laboratories. J. J. BLOOMFIELD. *Pub. Health Repts.* 43, 1895–7(1928).—Air tests in several labs. using 3 to 5 gal. benzene weekly showed 28 to 223 p. p. m. Although exposure may be intermittent, the fact that benzene concns. exceeded the industrial safety limit of 100 p. p. m. was taken as a warning to exercise more care in the handling of benzene in chem. labs. The use of toluene, xylene and high-flash naphtha instead of benzene for washing and cleaning purposes whenever possible is recommended. C. M. SALLS

Lessening menace of benzene poisoning in American industry. ALICE HAMILTON. *J. Ind. Hyg.* 10, 227–33(1928).—The use of benzene has markedly decreased in the past six years, especially in the making of sealing compds. for sanitary tin cans, in the making of rubber goods, in dry cleaning, and in quick-drying paints; but is still generally used in coating patent leather, in certain rubber cements, and in paint and varnish removers. C. M. SALLS

Microscopic pathology attending exposure of guinea pigs to vapors of ethyl bromide. C. P. WAITE AND W. P. YANT. *Pub. Health Repts.* 43, 2276–82(1928).—High concns. of EtBr vapors in air (18, 14, 13 and 6%) are markedly irritating to the lungs when breathed for a short period, producing an acute congestion and edema. Low concns. of EtBr vapor in air (2.4, 1.2, 0.65 and 0.32%) act as a toxin to the kidney, producing a diffuse acute parenchymatous nephritis. C. M. SALLS

Medical supervision of lead industries. L. SCHWARTZ. State Hyg. Inst., Hamburg. *Z. Gewerbehyg. Unfallverhüt.* 15, 16–22(1928); *Bull. Hyg.* 3, 581(1928).—S. believes in temporary suspension of doubtful cases and alternation of employment. He would exclude from employment persons having albumin in the urine, exaggerated knee reflexes, arteriosclerosis and high blood pressure. A scheme of diagnosis is given. GEORGE R. GREENBANK

Gravimetric determination of dust inhaled by workmen. A. I. BURSTEIN. *J. Ind. Hyg.* 10, 279–91(1928).—An instrument called the koniogravimeter was devised to imitate the functioning of the human respiratory app. The dust is removed from inspired air by passing through a weighed filter made of glass wool and cotton and attached to the nose of the experimenter. A special plunger pump may also be used

to pull the air through the filter. The use of the term "dust coefficient" is suggested to signify the av. weight of dust inhaled by a workman during an hour. C. M. S.

Method of action of silica dust in lungs. PATRICK HEFFERNAN AND A. T. GREEN. *J. Ind. Hyg.* **10,** 272–8(1928); cf. *C. A.* **21,** 972.—SiO_2 in stable combination and cryst. SiO_2 appear to be harmless while in those states. The harmful effects of colloidal SiO_2 appear to be due to its powerful potentialities as a colloid. Pulmonary silicosis is probably caused by the colloidal action of hydrated SiO_2, formed from minute particles of SiO_2 dust disseminated through the pulmonary tissue. Substances that are known to coagulate colloidal SiO_2 will prevent its harmful activity in the lungs. Such substances are clay, carbon, shale dust, etc. C. M. SALLS

System for maintaining constant heating value per unit volume in gases (U. S. pat. 1,686,751) **1.** Insulating paper (Fr. pat. 635,236) **23.**

Purifying gases. GEORG F. UHDE. U. S. 1,685,733, Sept. 25. See Brit. 250,963 (*C. A.* 21, 1320).

Purifying gases by adsorption. H. HOLLINGS, S. PEXTON, W. A. VOSS and GAS LIGHT & COKE CO. Brit. 284,758, Nov. 2, 1926. The contact chamber or its exposed surface is formed of material inert toward any constituents of a gas to be purified which otherwise might react to form metallic carbonyls. Cu, Zn or a refractory enamel may be used, and, in the case of coal gas or the like contg. impurities such as H_2S a material inert to such impurities is used. Preliminary purification may be effected for removal of any impurities such as carbonyls which may be present as by use of charcoal impregnated with chromates or dichromates or heated Cu. A filter of used adsorption material may be used for a preliminary removal of alk. liquid or metal particles.

Drying gases containing nitrogen oxides. I. G. FARBENIND. A.-G. Brit. 284,839, Jan. 1, 1927. The gases are treated with H_2SO_4 at a temp. of 30–100° and preferably under pressure (which may be 5 atm.). Such a quantity and concn. of H_2SO_4 are used that gases of a concn. of 60–65% are obtained and the gases may be treated with acid contg. N oxides so that the acid is denitrated.

Gaseous reactions. I. G. FARBENIND. A.-G. Fr. 635,619, June 8, 1927. Gaseous reaction products are purified as they come from the reaction chamber by passing them through or over substances such as SiO_2 gel, activated C or pumice, at a temp. only low enough to prevent any catalytic action. The method is applied to the purification of naphthoquinone from the oxidation of naphthalene, benzoquinone from benzene and its derivs. and BzH and BzOH from toluene. It is also applicable to decarboxylations and catalytic hydrogenations.

Catalytic reactions of gases. ROLAND E. SLADE (to Atmospheric Nitrogen Corp.). U. S. 1,686,349, Oct. 2. In effecting reactions such as NH_3 synthesis a stream of uncatalyzed gases is preheated by passing it in contact with a body of heat-storing material such as part of the catalyst itself and the gas stream is then passed through a body of catalyst to effect exothermic reaction progressing in the direction of flow of the gas and subsequently in contact with a second body of heat-storing material: periodically the flow is reversed to maintain proper temps. in the different portions of the app. (which is described).

Diffusion reactions between gases. HANS WALTER (to Verein für chem. Industrie A.-G.). U. S. 1,685,759, Sept. 25. Gases such as H and CO which react but slowly in simple mixt. are sepd. by a diffusion partition which may be formed of catalytically metallized asbestos and the gases diffuse into this partition and the product formed, *e. g.*, MeOH emerges from the partition under the diffusion pressure.

Separating gaseous mixtures with activated carbon. ARTHUR B. RAY (to Carbide and Carbon Chemicals Corp.). U. S. 1,685,883, Oct. 2. Water is supplied to active C to cool it during the absorption of gases such as gasoline from natural gas.

Treating gases with finely divided solids or liquids for adsorptions or various reactions, purifications, etc. METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 285,038, Feb. 9, 1927. A tower is used in which particles suspended in gases are displaced upwardly (suitably in a chamber flaring toward the top so that gases introduced at the bottom have their velocity decreased as they ascend). This treatment may be applied to the recovery of gasoline by adsorption from natural gas, removing S from gases by purifying reagents, treating starch with HCl for saccharification, washing gases with atomized liquids, distg. phenols from NH_3 water, oxidation of atomized metals or oils with O, producing powders by cooling atomized molten material, effecting crystn. by cooling atomized solns. and in carrying out catalytic processes.

Fractional liquefaction and separation of constituents of gases. GES. FÜR LINDE'S EISMACHINEN A.-G. Brit. 284,213, Jan. 24, 1927. In sepn. by partial condensation of constituents of coke-oven gas or other gas mixt., a gas of low b. p. such as N, under pressure, is cooled by the main body of constituents condensing out, and subsequently expanded and liquefied, serving as a bath for the last condensation stages. Various details and an app. are described.

Separating liquids. THOMAS FISHER. Fr. 32,572, Nov. 24, 1926. Addn. to 592,129. The app. described in Fr. 592,129 is used for sepg. water from heavier liquids and for separating liquids in general of different sp. gr.

Pervious material for purifying liquids by filtration. ARTHUR SCHREIER (to General Zeolite Co.). U. S. 1,685,204, Sept. 25. Filter stone or sand or other suitable porous material is treated with a light-sensitive compd. of Ag such as $AgNO_3$ or a Ag halide and the material is then exposed to light and treated to produce a surface deposit of metallic Ag.

Mixing solids with liquids such as in water purification. WILSON EVANS (to National Aluminate Corp.). U. S. 1,686,076, Oct. 2. A continuous stream of finely divided solids is projected at high velocity against the surface of water or other liquid with which the solid is to be mixed. An app. is described.

Detecting and removing impurities in steam or water heating systems used in chemical operations, etc. T. DÜRST. Brit. 284,215, Jan. 24, 1927. In steam- or water-circulating systems such as those used for heating or treating materials used in the manuf. of cellulose, oils or soap, impurities leaking into the system are detected by continuously withdrawing a small quantity of water from the return pipe and collecting this sample in an observation vessel. An app. is described.

Use of jets of liquid such as water for detaching cellulosic or other similar molded cap-shaped bodies from their molds. EMIL CZAPEK and RICHARD WEINGAND. U. S. 1,687,282, Oct. 9.

Purifying and fractionating oils and ketones. A.-G. FÜR KOHLENSÄURE-INDUSTRIE AND E. B. AUERBACH. Brit. 285,064, Feb. 12, 1927. The process of purifying and fractionating mineral oils by use of liquid CO_2 as described in Brit. 277,946 (*C. A.* 22, 2660) is applied to the treatment of mixts. of mineral oils with other substances, and to fats and fatty oils, essential oils, resin oils, tar oils, terpenes and other liquid hydrocarbons and ketone oils. Several examples are given.

Ion-concentration control. IRVING B. SMITH and EARL A. KEELER (to Leeds & Northrup Co.). U. S. 1,684,645, Sept. 18. A potential difference, varying in magnitude with variations in ion concn., is magnified by mixing with the soln. contg. the ions involved a proportioned quantity of a substance such as an aq. liquid and the magnified potential difference is utilized to control the ion concn. of the unmodified soln., *e. g.*, by appropriate neutralization. An app. is described.

Crystallization of salts without evaporation. A. A. SHALABANOV and S. A. ROGINSKII. Russ. 4164, Sept. 15, 1924. A block of frozen salt soln. and salt crystals is broken up and introduced into a container with a soln. of the same salts. The salt ppts. on the bottom during the melting of the ice and is collected in a receiver and the dil. salt soln. obtained from the melting ice is continuously withdrawn from the upper part of the app.

Catalytic oxidation. MONSANTO CHEMICAL WORKS. Fr. 635,717, June 9, 1927. A gaseous mixt. of O and an org. or mineral substance is heated in the presence of V_2O_5 and pyrovanadates. The process is used for the prepn. of H_2SO_4, phthalic anhydride, BzOH, BzH, salicylic acid and aldehyde, formaldehyde and AcH.

Controlling the rate of oxidation of metallic sodium or other materials. HECTOR R. CARVETH (to Roessler & Hasslacher Chem. Co.). U. S. 1,685,520, Sept. 25. A

mixt. of alkali metal and inert material, both in finely divided form, *e. g.*, a mixt. of Na 10 and Na_2O 90% is used for reaction with O to form addnl. Na_2O or Na_2O_2. More Na is added as required. An app. is described.

Dispersions. J. R. Geigy Akt.-Ges. Fr. 635,859, June 7, 1927. See Brit. 272,896 (*C. A.* **22,** 1859).

Briquetting ores, etc. Malmbrickett Aktiebolaget. Brit. 284,418, Nov. 8, 1926. Briquets, *electrodes* and the like are made from a mixt. of crushed ore, carbonaceous material, limestone or quartz, and tar or molasses (or both), with or without a small quantity of salt and are dried at about 150–300° for 1–3 hrs.

Method and apparatus for gravity separation of ores or other materials with an agitated mixture of liquid and solid of intermediate specific gravity. Thomas M. Chance. U. S. 1,685,521, Sept. 25. Mech. features.

Treating the interior of pipes with cleaning and coating materials. Nicolaus Meurer (to Metallogen G. m. b. H.). U. S. 1,687,102, Oct. 9. The treating material is injected under pressure and an app. is described by which substantially the same pressure may be maintained throughout the length of the pipe under treatment.

Countercurrent filtration system for oil, sugar solutions or other materials. Fred W. Manning. U. S. 1,686,092, Oct. 2. Treating solids such as fuller's earth or bone char are introduced into a zone of air or other elastic fluid situated above the level of a liquid to be filtered, the solids are distributed throughout the liquid and the liquid is then filtered through the solids. An app. is described. U. S. 1,686,093 and U. S. 1,686,094 also relate to constant renewal of filtration material in continuous filtration processes and describe app. Cf. *C. A.* **21,** 144.

Conducting layer of high resistance. Siegmund Loewe. Fr. 635,291, May 13, 1927. A layer is made of a dry residue from a soln. of colloidal C obtained after addition of about 3% of a protecting colloid such as a stannic colloid.

Refrigerating apparatus. Alfred M. Thomson (to Joseph Mercadante). U. S. 1,684,810, Sept. 18.

Vacuum refrigerating apparatus. G. Thomas and P. Schlumbohm. Brit. 284,233, Jan. 25, 1927. Structural features.

Refrigerating system of the absorption type. A. Einstein and L. Szilard. Brit. 284,222, Jan. 24, 1927. A diagram of partial pressures for various concns. is given with MeOH used as refrigerant and octyl alc. used as solvent. Other solvents referred to include "higher molecular paraffins," isoamyl ether, and other ethers and esters of the "lower molecular compds." contg. OH or NH_2 groups such as glycol. $CHBr_3$ may be used in systems without special liquid pumps.

Refrigerating apparatus of the absorption type. A. Lenning (to Electrolux, Ltd.). Brit. 284,193, Jan. 22, 1927.

Refrigerating system of the absorption type. Baltzar C. von Platen and Carl G. Munters (to Electrolux Servel Corp.). U. S. 1,686,425, Oct. 2.

Refrigerating system of the absorption type. Baltzar C. von Platen and Carl G. Munters (to Electrolux Servel Corp.). U. S. 1,685,764, Sept. 25.

Refrigerating apparatus of the absorption type. Alfred Richter (to A.-G. für Handels- und Industrie-werte Glarus). U. S. 1,685,340, Sept. 25.

Refrigerating system of the continuous-cycle absorption type. Platen-Munters Refrigerating System Aktiebolag (to Electrolux, Ltd.). Brit. 285,016, Feb. 8, 1927. Structural features.

Refrigerating system of the reversing absorption type. Bayer Geb. Brit. 284,987, Feb. 7, 1927. Structural features.

Refrigerating system of the compression type. A.-G. Brown. Boveri, et Cie. Brit. 285,003, Feb. 8, 1927.

Refrigerating apparatus of the compression type. Akt.-Ges. Brown, Boveri, et Cie. Brit. 284,646, Feb. 2, 1927. Structural and elec. features.

Refrigerating apparatus of the compression type. E. H. Hull (to British Thomson-Houston Co., Ltd.). Brit. 284,729, Feb. 5, 1927. Structural features.

Refrigerating apparatus of the compression type. C. Steenstrup (to British Thomson-Houston Co., Ltd.). Brit. 284,730, Feb. 5, 1927. Structural features.

Electrical insulation containing natural or artificial resins. H. L. Watson (to British Thomson-Houston Co.). Brit. 284,232, Jan. 25, 1927. Tubes and spools for elec. app., or other molded articles, are made from kraft sulfate sheet wood pulp or similar cellulosic sheet material with felted fibers of natural length, impregnated with shellac, bakelite, glycerol-phthalic anhydride resin or the like.

Heat-insulating material suitable for use on pipes, in walls, etc. Warren M. Emerson (to Certain-teed Products Corp.). U. S. 1,687,285, Oct. 9. A dry mixt.

formed from calcined gypsum 400 lbs., a carbonate such as $NaHCO_3$ 4 lbs. 13 oz., $Al_2(SO_4)_3$ 10 lbs., a colloid, lime 1 lb. 12 oz. and an acid retarder, *e. g.*, oxalic acid 1 lb. 5 oz., is mixed with water.

Heat insulation on walls, etc. E. H. Wenzel. Brit. 284,849, Jan. 15, 1927. Finely divided dry material such as fragments of paper, wood fiber or corn stalks are projected on walls or other surfaces and caused to adhere to each other and to the surface by glue, waterglass or other glutinous adhesive which may be rendered vermin-proof by addn. of an As compd. or other suitable substance. An app. is described.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Recreational use of watersheds of public water supplies. W. L. Stevenson and H. E. Moses. *Water Works* 67, 254–5(1928).—There has been a pressing demand to use watersheds of water supplies for recreational uses such as camping, fishing, bathing, etc., and one state has passed a law allowing this use of watersheds provided no trespass is committed. The riparian rights of owners of land abutting on water courses complicate this problem. Remedies which are suggested for safeguarding public supply watersheds against contamination through recreational use include zoning, placarding, sanitary control, education of the public and legislation. C. C. Ruchhoft

Contamination of well and collecting reservoir public water supplies. Harry F. Ferguson and Clarence W. Klassen. *Water Works* 67, 209–13(1928).—Instances of well and reservoir contamination in Illinois resulting from the following causes, surface contamination of well through open top, underground contamination of well, surface contamination of an open reservoir, surface contamination of a reservoir through defects in the cover and underground contamination of a reservoir, are described. C. C. Ruchhoft

Water-works practice. W. E. MacDonald, *et al.* *J. Am. Water Works Assocn.* 20, 381–9(1928).—Tabulated answers and percentages to questions of all kinds; 11% cities have phenol tastes, 45% have algae troubles. Many remedies are listed. D. K. French

Measurement of the quality of water. Jack J. Hinman, Jr. State U. of Ia. *Proc. Iowa Acad. Sci.* 34, 69–75(1927).—A review and discussion with bibliography appended. W. G. Gaessler

Time savers in water analysis. F. E. Daniels. *Public Works* 59, 213–5, 282–4(1928).—The routine practices of the lab. of the Pennsylvania State Board of Health in water analysis are described in detail. Individual counter weights for silica dishes, a method of fast weighing and a cabinet desiccator expedite the work. The app. and methods for the detn. of free and albuminoid ammonia, chlorides, nitrates, nitrites, total hardness, alky., color, odor, H ion, solids, Fe and O consumed are included. C. C. Ruchhoft

The determination of the residue on evaporation and of its loss on ignition. Horn. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 3, 313–4; *Chem. Zentr.* 1927, II, 2334.—Detailed description of the detn. of the residue on evapn. and the loss on ignition in waste, drinking and technical water. Information is given on the detn. of the total amt. of the insol. material of a water and the estn. of its loss on ignition in order to get an approx. idea of the amt. of the insol. org. constituents. G. Schwoch

The determination of carbon dioxide. Eckerlin. Staatl. Mainwasseruntersuchungsamt, Wiesbaden. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 2, 40–3 (1926); *Chem. Zentr.* 1927, II, 1745.—Ordinary methods used in *water analysis* for the detn. of total CO_2, bicarbonate CO_2, free CO_2 and active CO_2 are described. C. C. Davis

The determination of hardness (of water). Habrich. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 2, 39–40(1926); *Chem. Zentr.* 1927, II, 1745.—A description of the Blacher method (cf. *C. A.* 7, 1394). C. C. Davis

Determination of chlorides. Horn. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver, Wasserversorg. Abwässerbeseitig.* 2, 257–8(1926); *Chem. Zentr.* 1927, II, 1746.—A discussion of the well-known process of Mohr, with the modifications of the process which are necessary with colored waters and waste waters. C. C. Davis

The detection, determination and importance of free chlorine and of hypochlorites

in water. H. KLUT. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 3, 184–91; *Chem. Zentr.* 1927, II, 1879.—The detection of Cl and hypochlorites by KI-starch, *o*-tolidine and dimethyl-*p*-phenylenediamine and their detn. with *o*-tolidine and benzidine are described, and the importance of the *Cl treatment of drinking water*, etc., is discussed. C. C. DAVIS

The titration of chlorine in waters with a high salt content. L. W. HAASE. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig* 3, 121–6; *Chem. Zentr.* 1927, II, 1879.—A crit. survey of methods ordinarily used in oceanography for detg. the Cl content of strongly salt waters. A very precise detn. of the Cl content is of great importance in oceanography because with the aid of the Cl value, the total salt content and the d. can be calcd. by special formulas. C. C. DAVIS

New indicator for chlorine. KNUT ALFTHAN AND ALEC C. JARVIS. *J. Am. Water Works Assocn.* 20, 407–11(1928).—After considering KI and starch, benzidine and *o*-tolidine, the authors describe dimethyl-*p*-phenylenediamine hydrochloride, which gives with Cl a rich red color and is sensitive to 0.01 mg. in 100 cc. of water. Its disadvantages are: sensitiveness to Fe greater than 0.1 mg. per l. and the necessity of holding the p_H of the sample between 2.6 and 3.4. On the other hand the reaction is rapid and sensitive and but one soln. (methyl red) is required for color comparison. D. K. FRENCH

Preparation of the *o*-tolidine reagent for free chlorine. C. S. BORUFF, S. J. VELLENGA AND R. H. PHELPS. *J. Am. Water Works Assocn.* 20, 404–6(1928).—Theriault's method using HCl is considered most rapid and reliable. The acid concn. should be kept below 178 cc. per l. D. K. FRENCH

The gravimetric and the volumetric determination of lime in water. R. SCHMIDT. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 2, 242–7(1926); *Chem. Zentr.* 1927, II, 1745.—Up to the pptn. and filtration of the oxalate ppt. the gravimetric and volumetric methods for the detn. of CaO run parallel, but from this point on the volumetric method has very important advantages. C. C. DAVIS

Determination of plankton (in water). W. F. LANGELIER. *J. Am. Water Works Assocn.* 19, 408–15(1928).—For lab. work the Sedgwick-Rafter method, described in the A. P. H. A. Standard Methods of Water Analysis, has many advantages, but the method of counting is tedious. In routine examn. of water supplies, with the object of controlling the quantity of plankton present, Henson's net method is preferable. The nets used are conical with a Cu or glass container. The vol. of plankton collected is measured after settling or centrifuging and the results are quoted in cc. per cu. m. The main errors of this method depend on the velocity of haul and the ratio of net surface to area of circle. Certain small plankton pass through the net, but these have seldom been shown to have a deleterious effect on taste or odor. Their presence is often indicated by a loss of transparency by the water, and this is used to indicate the need for $CuSO_4$ treatment. B. C. A.

The microscopic life in water. ASA C. CHANDLER. *Proc. 10th Texas Water Works Short School* 1928, 155–9; *U. S. Pub. Health Eng. Abstracts* E-637a, 68(1928).—A discussion of the part played by microscopic organisms in water; factors which influence the development of microscopic organisms with explanations of the influence of sunlight, temp., overturn, food supplies, and aeration; relation between stream pollution and abundance and character of microörganisms; by-products of plant life, such as odor, taste, and color in water; effect of growths on pipes, sand filter beds, and O_2 content of water; and methods for control, such as $CuSO_4$ or Cl_2. J. A. K.

Bacteria growing on leather packing cause errors in sampling. H. H. GERSTEIN. *Eng. News-Record* 101, 407(1928).—The quality of the unchlorinated water in the tunnels between the intake cribs and pumping stations in Chicago is detd. by bacterial analyses of samples of the water collected from hand-operated well pumps. Recent analyses indicated sewage pollution of a degree which could not be accounted for. Check samples taken from the main pumps and with deep water sampling app. showed no such pollution. The leather packing on the plunger and suction valves in the pump cylinders were examd. and found to be contaminated with organisms which conformed to the A. P. H. A. standard test for *B. coli*. Several of these leathers placed in sterile water in Mason jars about 1 year ago have maintained a prolific growth of these organisms, the no. at times reaching as high as several million per cc. The problem has been solved by installation of specially designed pump cylinders which are metallic throughout, the valves being of the ball type. It is pointed out that samples drawn from fire hydrants may be contaminated in the same manner. R. E. THOMPSON

Algae control by creating turbidity at Louisville, Ky. W. H. Lovejoy. *Eng. News-Record* **101,** 505–7(1928).—Filter runs are seriously reduced by algae during certain periods at the Louisville plant. Filter runs have been as short as 30 to 60 min. and wash water as high as 12% of the water filtered. It was observed that this condition obtained when the turbidity of the raw water was low, an increase of as little as 50–75 p. p. m. of turbidity causing disappearance of the algae and lengthening of the filter runs. During two periods in 1927 low runs were successfully combated by artificially increasing the turbidity by pumping sludge from the bottom of the preliminary settling basins to the raw-water inlet of the basins by means of a dredge boat carrying an 8-in. electrically operated dredge pump. Five hrs.' operation of the dredge causes sufficient stirring up to give a turbidity of 500 at the inlet of the basins for 24 hrs. About 80% of this turbidity settles in the 2 preliminary basins, removing a large no. of organisms, and the remaining 100 p. p. m. of turbidity provides a nucleus for an excellent floc in the coagulation basin which carries down an additional no. of organisms. During the treatment the bacterial count and *B. coli* content of the water leaving the basins were lower than in the incoming raw water. Observations have indicated that shortening of the filter runs results from gradual accumulation of algae on the filter sand, which are not removed to any great extent by washing. In future it is intended to create artificial turbidity whenever the river water turbidity drops below 50 p. p. m. and runs show any appreciable decrease. It has been found that a filter with sand of 0.48–0.50 mm. effective size will run on an av. 50–100% longer; during short run periods due to algae, than one having sand of 0.40 mm. effective size, and that the unit with the finer sand will drop off in length of runs more rapidly and regain more slowly than one with the coarser sand. The following treatments were experimented with previously: $CuSO_4$, lime, overdosing with alum, coagulation with Na aluminate and alum, and prechlorination. In addn. the filter sand has been treated with $CuSO_4$, NaOH and hypochlorite. Of these, $CuSO_4$ treatment only, gave temporary relief, and then only when the subsidence period was 4 days or more. The dredge is also used for cleaning the basins without draining, the cost being about 3¢ per cu. yd. R. E. Thompson

Destruction of bacteria by ammonia and chlorine. W. Olszewski. *Chem.-Ztg.* **51,** 269–70(1927); cf. *C. A.* **20,** 2713.—The results are described of the bacteriol. and chem. examn. of water in a swimming pool after treatment with Cl and NH_3. The gases, which are used in the ratio of 2 parts of Cl to 1 part of NH_3 by wt., probably owe their bacteriol. action to the formation of chloramines. This method is superior to treatment with Cl as no odor is perceptible, the water remains clearer and a careful regulation of the amt. of reagents to be added is not required. W. L. D.

Example of the reactivity of siliceous algae to the salt content of water. Konrad Gemeinhardt. Landesanst f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **1,** 60–1; *Chem. Zentr.* **1927,** II, 1744.—The fresh water diatom *Synedra ulna* is especially sensitive to a high salt content of the water, whereas the development of *Synedra pulchella* is inhibited by lowering the salt concn. C. C. Davis

Dosing apparatus. Wynkoop Kiersted. *Proc. 10th Texas Water Works Short School* **1928,** 54–7; *U. S. Pub. Health Eng. Abstracts* **E-637a,** 68(1928).—K. discusses the 2 basic methods of prepg. and distributing the coagulants by the soln. method. Although soln. feed would probably be more economical in the larger water-works plants, the dry feed method finds greatest favor in the smaller plants. Various methods of mixing the coagulants with the raw water are also discussed. J. A. Kennedy

Present tendencies regarding disinfection. E. C. Farr. *Munic. Eng. Sanit. Record* **81,** 333(1928).—F. advocates "current" disinfection as against present waste of public funds by "terminal" disinfection. C. H. Badger

The water chlorination equipment of the Schau- und Lehrsammlung der Landesanstalt. J. Wilhelmi. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **3,** 198–202; *Chem. Zentr.* **1927,** II, 1878.—A description with drawings of a Cl disinfecting equipment of the Bomag-Meguin-A. G., the chlorination equipment of Dr. Ornstein, and the electrolytic plant of Arthur Stahl, Aue, i. Sa. J. S. Reichert

The halogens and public water supplies. Joseph S. Hepburn. Hahnemann Med. Coll., Philadelphia. *Hahnemannian Monthly* **63,** 641–9(1928); *Catalyst* **13,** No. 7, 21–4; No. 8, 7(1928).—A review devoted to iodization, the use of Cl_2, hypochlorites, chloramines (Cl_2 plus NH_3) and other Cl compds., superchlorination followed by dechlorination, the "chlorine taste" and its prevention and a bibliography. "At the present time, chlorination of municipal water supplies is necessary to prevent epidemics of water-borne diseases. Possibly, in the future, other methods of sterilization may be

devised which will be applicable on a large scale at a low cost and will obviate the addition of bactericides to the water." JOSEPH S. HEPBURN

The oxygen content of water. H. STOOFF. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **2,** 13–21 (1926); *Chem. Zentr.* **1927,** II, 1743.—With the aid of 3 tables of the soly. of air in water at 1–30°, of O in distd. water at 0–90° and of O in salt water (0.5–2.0% Cl) at 0–30°, the significance of O in natural waters is discussed. C. C. DAVIS

The function of aeration in water purification. N. T. VEATCH, JR. *Proc. 10th Texas Water Works Short School* **1928,** 172–7; *U. S. Pub. Health Eng. Abstracts* **E-637a,** 67(1928).—Expts. with simple aerators have proved: O_2 may be added to water to the point of satn., CO_2 may be largely, but not completely, removed; *odors and tastes,* due to gases of decompn., may be partially removed but if due to products of org. decompn., the effect is negligible; odors and tastes due to coal tar, phenol and similar wastes are little affected; H_2S and odors due to over-chlorination may be satisfactorily removed; the oxidation of org. matter is negligible but inorg. compds. as Fe and Mn are largely, but not completely, oxidized; bacterial content of the water is often decreased; the economy and effectiveness of treatment with ordinary coagulants are usually increased; corrosiveness of soft or peaty waters is usually increased, whereas surface supplies are not usually affected. Four different types of aerators are discussed: air lift, injection, gravity and fountain aerator. J. A. KENNEDY

Presence and detection of arsenic in water. H. KLUT. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **3,** 191–4; *Chem. Zentr.* **1927,** II, 1879.—Following a discussion of the presence and limits of toxicity (0.2 mg. of As_2O_3 per l.), the detection of As by the methods of Gutzeit and of Beck, Merres and Smith are described. C. C. DAVIS

Lead poisoning from lead-piped water supplies. WADE WRIGHT, C. O. SAPPINGTON AND ELEANOR RANTOUL. *J. Ind. Hyg.* **10,** 234–52(1928).—Of ninety sources including city, well and spring waters, all contained lead, and 35 of them caused poisoning as detd. by hemoglobin detns. and the making of blood smears. Of 253 exposed persons, 63 or 24.9% were poisoned. C. M. SALLS

The allowable limit of lead in drinking water and water for other uses. HANS BEGER. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwasserbeseitig.* **2,** 171–3(1926); *Chem. Zentr.* **1927,** II, 1743.—A study of the literature shows a disagreement over the limiting value above which Pb in water is toxic, the limits varying from 0.025 to 1.0 mg. of Pb per l. C. C. D.

Manganese in Iowa City waters. EDWARD BARTOW AND W. T. BAILEY. *Proc. Iowa Acad. Sci.* **34,** 191–5(1927).—A deposit showing quantities of MnO_2 as indicated by the evolution of Cl from HCl was found in the H_2O pipes from University of Iowa well No. 2 which is located at the laundry. The purpose of the investigation was to det., if possible, whether or not the Mn occurred in any definite strata and whether or not it could be eliminated from wells by casing out Mn-bearing waters. Samples from about 50 wells in Iowa City and the immediate vicinity were analyzed and practically all were found to contain small amts. of Mn. The fact that wells located in the glacial drift contain a fairly large amt. of Mn (0.13 to 0.25 parts per million) together with the extremely large amt. found in the infiltration gallery (1.8 parts per million) would indicate that the Mn occurs largely in glacial and alluvial drifts. The presence of fairly large amts. of Mn in such wells in Iowa City might be explained by the fact that the limestone is not solid, but contains many large crevices through which soil waters may be carried into wells. Results indicate that Mn may be concd. in pockets, as is true of iron, and that it would be impossible to predict where a well might be located to secure a H_2O free from Mn, except perhaps in deep wells in rock. Inasmuch as 5 wells penetrating limestone to depths of from 180 ft. to 400 ft. show less than 0.1 p. p. m. it might be possible to prevent Mn-bearing waters from entering such a well by having a good junction of the casing to shut out the waters from the drift. A short bibliography is appended. W. G. GAESSLER

Iron and manganese removal at Wausau, Wisconsin. EMIL FLATTER. *Am. City* **38,** 125–6; *J. Am. Water Works Assoc.* **20,** 275(1928).—The supply from a well is of poor physical character. After aeration over coke and MnO_2 ore, lime and alum are added, and after coagulation in a Dorr clarifier, the water goes to sedimentation basins and is then filtered. Final chlorination is unnecessary. D. K. FRENCH

English view on rapid sand filtration. S. W. FARRINGTON. *Public Works* **59,** 278–80(1928).—F. comparing American and British water-works practice found that in general American practice is much more standardized than British; but automatic control of chem. dosing for proportioning in accordance with water flow is more common

in England than in America. The use of settling tanks is less common in British practice. On the av. Americans use higher filtration rates. Filter washing with water and air or stirring while not usually used here are considered essential in England.
C. C. RUCHHOFT

What is the best rate of filtration? R. B. SIMMS. *Water Works Eng.* 81, 19; *J. Am. Water Works Assoc.* 20, 278(1928).—The usual rate is 2 gal. per min.; rate of wash water about 15 gal. per min.; length of wash 5 to 6 min. and amount, less than 5% of water filtered.
D. K. FRENCH

Elements of successful coagulation and filtration. HARRY N. JENKS. *Water Works* 67, 203–6(1928); *Can. Eng.* 54, 630(1928).—Adequate pretreatment of the water applied to rapid sand filters is an important factor in maintaining high standard effluents. The proper design of chem. feed app. and of the mixing devices is necessary for insuring accurate measurement of chemicals and proper flocculation. Mech. stirring devices are considered better than gravity mixers. The well-formed floc should not be broken up and the well-clarified water should carry a residual well-formed floc as it reaches the filters. The influences of plant design and operating methods on filtration are discussed.
C. C. RUCHHOFT

Some old and new factors in water softening. DANIEL H. RUPP. *Proc. 10th Texas Water Works Short School* 1928, 115–7; *U. S. Pub. Health Eng. Abstracts* E-607, 60(1928).—Numerous features and methods employed in water softening such as lime and soda ash, split treatment of over-softening the larger portion of flow with subsequent mixing with untreated portion, use of sludge return, and use of the more modern mech. mixing chambers and clarifiers are discussed. Larger alum dosage to obtain reduction of residual hardness below the theoretical quantities which the coagulant should remove and pebble lime as an aid to filtration and softening due to its lower cost per unit of CaO and ease of handling are considered. Reference is made to recarbonization of settled softened water for the purpose of eliminating incrustation of filters and distribution systems and the strides made by the zeolite process in large municipal plants. The treatment known as "the use of CO_2 as a softening reagent together with the excess lime treatment" used at the Piqua, Ohio, softening plant is given in detail. A distinct advantage of the excess lime treatment is the effectual disinfection by the causticity in what is usually the first step of the purification process, the coagulating basins, leaving the filtration and chlorination processes a double factor of safety.
J. A. KENNEDY

Zeolite softening of lime-treated water at Columbus, Ohio, water-softening and purification works. CHARLES P. HOOVER, VIRGIL L. HANSLEY AND CLYDE Q. SHEELY. *Ind. Eng. Chem.* 20, 1102–5(1928).—The purpose of this investigation was to det. whether or not it would be better and more economical for this city to continue to soften its public water supply with lime and soda ash or to use lime treatment in connection with zeolite as a substitute for the soda-ash treatment. The investigation is not as yet complete. Details of operation, data so far accumulated and savings to the city are given.
J. A. KENNEDY

Modern water-softening plant. ANON. *Textile Recorder* 46, No. 542, 45–6(1928).—An illustrated description of the "Osilameter" automatic feed gear for lime and soda ash made by the Paterson Engineering Co., London.
RUBY K. WORNER

Twenty years of experience of sanitary progress in India. F. C. TEMPLE. *J. Roy. Sanit. Inst.* 49, 13–24(1928); *U. S. Pub. Health Eng. Abstracts* E-607c, 17 (1928).—Public water supplies increased from 35 in 1905 to 92 in 1927 in 5 provinces. By judicial use of H_2SO_4 and soda ash, all but one ton of silt p. m. g. is brought down in the settling basins. Drainage progress has been even greater. Expts. have shown that for Indian conditions 2 cu. ft. per user, and 5 and 40 gal. limits of dilns. are approx. the correct septic-tank capacity and sewage dilns.
J. A. KENNEDY

The carbon dioxide tension of the Fraser River and its lower tributaries and of certain tributaries of the Columbia River. EDWIN B. POWERS AND THERSA A. HICKMAN. Univ. of Tennessee. *Pub. Puget Sound Biol. Sta.* 5, 373–80(1928).—Lakes and rivers draining lakes had in general a lower CO_2 tension, av. 0.57, than rivers not fed by lakes, av. 1.05 mm. Hg. Typical mountain streams apparently had a higher CO_2 tension than streams of the lower land. Certain streams, as the Clark Fork of the Columbia River and the Yellowstone River had very low CO_2 tensions, the reasons for which are not well understood. **The carbon dioxide tension, oxygen content, the p_H and the alkali reserve of natural waters mostly of the western portion of the U. S.** EDWIN B. POWERS. *Ibid* 381–91.—The waters of lakes and of rivers draining lakes, other things being equal, had a lower CO_2 tension and a higher O content than

the waters of rivers not fed by lakes. Mountain streams in general had a lower p_H than the streams of the lower lands. L. W. Riggs

Chemical study of the waters of Argyle Lagoon. I. Phoebe Blalock and Thomas G. Thompson. Univ. of Wash. *Pub. Puget Sound Biol. Sta.* 5, 341–53(1928).—The sea water of Argyle Lagoon during the summer months differs from the av. sea water at the Puget Sound Biol. Sta. in its higher temp., greater concn. of dissolved O and a slightly greater p_H. Differences between surface and bottom samples show a definite stratification of the water, even in these comparatively shallow depths. This is especially noticeable at or near the high tides. The condition of the water in the lagoon is affected both by tidal changes and by local meteorological conditions; the influence of the latter predominates except at times of high tide. The org. silt at the bottom of the lagoon contained H_2S. The presence of this gas was not detected in the water. **Chemistry of the waters of Argyle Lagoon. II.** Geo. H. Hitchings, Seldon P. Todd and Thomas G. Thompson. *Ibid* 325–32.—In addn. to the differences noted above, the water of the lagoon has a lower concn. of dissolved and of chem. combined CO_2 than av. sea water. During the summer months, the salinity of the surface waters of the lagoon varies with that of adjacent waters, while the salinity at the bottom remains practically const. With the possible exception of organisms living at the bottom in the deeper portions, the differences in the marine life of the lagoon from that of adjacent waters cannot be attributed to salinity differences. The seasonal variations in the waters of the lagoon are much more marked than those of adjacent waters. L. W. Riggs

Results of a systematic study of water from the Vistula. T. Kirkor. State Hydrological Lab., Warsaw. *Przemysl Chem.* 12, 285–94(1928).—The period covered by this investigation was from March, 1923 to July, 1924. Samples of water were drawn from the Vistula above Warsaw and 42 chem. and 27 bacteriol. analyses were made. The compn. of the water changes over a wide range at different seasons. The averages in mg. per l. were: suspended matter 72.2; residue dried at 110° 214.7; NH_4 0.10; NO_3 trace; NO_3 0.7; SO_4 14.3; Cl 11.2; O_2 (72 hrs. at 20°) 2.2; Fe 0.24; total hardness 14.7 degrees; permanent hardness 0.6; CaO 68.0; MgO 10.0. The bacteriol. analyses gave: bacteria per cm.^{3} 2000; titer for *B. coli comm.* 0.05. Phys. properties: turbid, and of yellow color; the suspension is largely sand and clay. Analyses of waters from Oder, Laba, Danube, Neva, Dnieper and Vistula 50 yrs. ago are given for comparison. A. C. Zachlin

Clarification of the Catskill water supply of New York City. Wm. W. Bush. *Water Works* 67, 141–4(1928).—During November 1926 very heavy rains resulted in turbidities around 100 in the Schoharie and Ashokan reservoirs of the Catskill system. Examn. showed that prolonged standing would not satisfactorily remove this turbidity and therefore clarification with soda ash and alum was necessary. The soda ash was introduced into the aqueduct at the Ashokan reservoir 75 miles above the Kensico reservoir and the alum was added to the aqueduct at Pleasantville 3 miles upstream from the Kensico reservoir. The floc settled in the Kensico reservoir and a satisfactory water was produced. The treatment was continued from December 1926 until May 1927. C. C. Ruchhoft

Factors considered in the design of the Abilene, Texas, water-purification plant. O. K. Hobbs. *Proc. 10th Texas Water Works Short School* 1928, 57–61; *U. S. Pub. Health Eng. Abstracts* E-576b, 56(1928).—Lake Abilene, located 19 mi. S. W. of the city of Abilene, furnished that town with a water supply by gravity through 18 in. cast iron pipe to two 20-million-gal. storage basins. A 4 m. g. d. treatment plant has been designed to include special methods of proportioning the chem. dosage. Specially designed chem. control machines have been installed, operating under the principle of the under-shot water wheel placed in a channel carrying water to the treatment plant, the wheel acting as a positive displacement meter and furnishing power to drive the machines which mechanically measure out the lime slurry and the iron soln. used in the softening and coagulation of the raw water. Special types of mixers and weirs have been included in the design and are discussed. The sedimentation basins are sepd. into 2 compartments, the first giving a detention period of 45 mins. and taking 95% of the deposit. The settled coagulant can be withdrawn from the basin daily by the hopper bottom flushing arrangement. The basin is baffled on the over and under system and all units are arranged so that the plant can be operated by one attendant. The cost of treating this water, including labor, power, chemicals and interest and depreciation on the plant, amounts to $26 at a 2 m. g. d. rate. Expectations are that this cost will be reduced to $5.94 when the designed capacity of the plant is reached. J. A. Kennedy

The new Bloomington, Indiana, water works. PAUL HANSEN. *Water Works*, **67**, 219–21(1928); *U. S. Pub. Health Eng. Abstracts* **E-576b**, 56(1928).—Historical development of this city's water works is given. In 1927, pumping and filtration works of 2 m. g. d., which may be extended to 8 m. g. d., were authorized. J. A. KENNEDY

Municipal undertakings at Exmouth (England). SAMUEL HUTTON. *Munic. Eng. Sanit. Record* **81**, 332–3(1928).—The consumption of water varies from 410,000 gals. (Jan., 1928) to 600,000 gals. (summer) per 24 hrs. The trunk-main capacity is 760,000 gals. The available supply is over 1 million gals. New mains are being built as required. All the sewage discharges into the channel at all tides; that from about $^2/_3$ of the population is by gravity and the rest by pumping. The system is 28 yrs. old; it will be improved at the expiration of certain loans in 1930. C. H. BADGER

Scarborough (England) water works. HERBERT LAPWORTH. *Munic. Eng. Sanit. Record* **81**, 320(1928).—The water supply is obtained from a deep well and bore hole 428 ft. deep. Two low lift and 2 high lift pumps operated by 2 steam engines pump 1,300,000 gals. per day. The low lift pumps raise the water from the wells to the sand filters and the high lift pumps force the filtered water through $3^1/_2$ miles of main to service reservoirs. The present pumping plant is over 40 yrs. old. The new scheme provides for a water supply of 2,640,000 gals. per day (an addnl. well and bore hole 430 ft. deep having been completed) pumped by 2 low lift and 4 high lift pumps, electrically driven, into 2 mains. The estd. cost is £ 102,150. C. H. BADGER

New water works and filtration plant at Laredo, Texas. R. T. REILLY. *Water Works* **67**, 247–8(1928).—The new filter plant located on high ground upstream from the source of pollution has its intake in the Rio Grande River and includes low lift pumps, aerators, mixing and coagulation basins, filters, clear well and high lift pumping station. The mixing will be accomplished in circular tanks by peripheral velocity without mech. agitation. The settling basins are circular with a total detention period of 6 hrs. There are 4 filters with a total capacity of 6 m. g. d. C. C. RUCHHOFT

The newly completed water works of the city of Oneida, New York. NICHOLAS KNIGHT. Cornell Coll., Mt. Vernon, Ia. *Proc. Iowa Acad. Sci.* **34**, 219(1927).—The supply comes from Florence Creek, 22 miles north of the city. A 20-in. main conveys the H_2O. The watershed contains 17 sq. miles, very sparsely settled and the danger from contamination is slight. There is an unusual amt. of pptn in that section of New York State; in the dryest year of recent times, the rainfall was 41.28 in. A dam 400 ft. long and 50 ft. high, near the village of Taberg will impound the H_2O, 200,000,000 gals. It is estd. that this would furnish the city a 3 months' supply, should no rain fall during the period. The former supply was found unusually hard in $CaSO_4$; an analysis of the new supply showed it to be unusually soft and pure. W. G. G.

San Francisco water supply. G. A. ELLIOTT. *J. Am. Water Works Assoc.* **20**, 294–307(1928).—The nature and extent of the Hetch Hetchy development are described While the water is of excellent quality, as a precaution, chlorination plants are located at the outlets of all sources of supply. D. K. FRENCH

The St. Louis water problem. L. A. DAY. *Proc. 10th Texas Water Works Short School* **1928**, 105–11; *U. S. Pub. Health Eng. Abstracts* **E-607b**, 62 3(1928).—D. describes the source of supply of the water, its delivery from the Mississippi River at the Chain of Rocks Plant to the grit chamber and mixing conduit where milk of lime and a soln. of sulfate of Fe are added. There are 6 coagulation basins, each of 30 m. g capacity. Secondary coagulation with Al sulfate is provided. There is included a description of the Howard Bend Plant on the Missouri River. Advantages expected from the new plant are discussed. J. A. KENNEDY

Boiler-feed water W. R. MCALLEP. *Facts About Sugar* **23**, 950 1(1928). —To replace steam losses under the conditions obtaining in Hawaiian sugar mills some 130 to 260 lb. of make-up water is required per ton of cane. Fresh water is generally used for this purpose. M. recommends the use of condensed vapors (as in beet sugar plants), of which there is an excess of about 400 lb. per ton of cane after the requirements of the maceration and filters are satisfied For maintaining the required p_H in the boiler water he suggests the use of lime water in preference to Na_2CO_3. NaOH, derived from the latter by hydrolysis under modern boiler pressures, may accumulate to such a concn. around rivets and in other capillary spaces as to involve embrittlement hazards. M. J. PROFFITT

Treatment of boiler feed waters of low incrustant content. S. C. JOHNSON. Water Supply Dept. Chesapeake and Ohio R. R., Huntington, W. Va. *Ind. Eng. Chem.* **20**, 1071–2(1928).—Few water supplies are so good that some form of treatment does not improve them. The controlled addn. of predetd. amts. of suitable softening agents and

a satisfactory blowoff schedule amply reward the efforts and expenditures involved in the treatment of waters of even low incrusting solid content. J. A. Kennedy

Minerals affect feed water. J. B. Romer. *Power Plant Engineering* **32**, 923 (1928).—Impurities in boiler feed water result in scale, corrosion, embrittlement, priming and foaming with consequent weakening, early failure and wet steam. Boiling water at atm. pressure removes Ca, Mg and carbonate. These, in pptd. form, should be allowed to settle out before the water enters the boiler. The decreasing soly. of $CaSO_4$ with rise in temp. causes it to ppt. on the hottest parts, making an insulator and causing blister, and eventually ruptures in boiler tubes. Non-scale-forming salts, such as $MgSO_4$, $CaCl_2$, $MgCl_2$ and $NaHCO_3$ after they have been hydrolyzed may cause corrosion. Ideal feed water is hard to obtain and treatment inside the boiler is never as good as outside treatment. S. D. Poarch

Corrosion of iron water pipes and methods of treating water to reduce corrosion. J. R. Baylis. *Baltimore Eng.* **2**, 6–10; *J. Am. Water Works Assocn.* **20**, 285.—Much theoretical discussion is added to the material of a previous paper (*C. A.* **21**, 2751). D. K. French

Prevention of corrosion in the chemical cleaning of condensers and boilers. Fr. Lieneweg. *Wärme* **50**, 507–11; *Chem. Zentr.* **1927**, II, 1301.—The influence of boiler scale on the economy of condensers and boilers is discussed. and the necessity of a thorough and frequent removal of the scale emphasized. The corrosion sometimes occurring in the cleaning (with HCl, etc.) is limited by adding preservatives. The various kinds of corrosions are described and advice is given for their prevention. G. Schwoch

Experience with a boiler-scale preventive. N. Broglio. *Arch. Wärmewirt.* **9**, 111–5(1928).—B. describes the good results obtained with a proprietary product, "Tartricid," stated to consist mainly of substances similar to *tannic acid.* E. W. T

The countercurrent electro process. E. Schulz. *Arch. Wärmewirt.* **6**, 247–8 (1925).—The front and back of the boiler are connected to the 2 sides of a d. c. line through 2 C-filament lamps. This prevents the formation of boiler scale, and loosens old scale. The mechanism is doubtful; presumably it is an electrolytic effect. Ernest W. Thiele

What effect has the introduction of sulfite waste liquor upon the acidity of river water? Erik Öman. Techn. Hochschule, Stockholm. *Papier-Fabr.* **26**, 529–32 (1928).—The titratable acidity is of less importance than the actual acidity, which was detd by colorimetric p_H measurements on samples removed periodically from various points in the stream. The values found were: river water above mill, 6.6; with waste liquor in 1:350 diln., 4.8; with waste liquor in 1:3000 diln., 6.4. The buffer capacity of the water may have a considerable effect. Atm. oxidation of SO_2 to SO_3 may further decrease the p_H by about 0.2 units. The highest acidity found is probably without harmful effect upon aquatic life; this does not preclude such an effect from other components of the liquor. R. H. Doughty

Stream pollution—self purification of streams. H. W. Streeter. *Proc. 10th Texas Water Works Short School* **1928**, 240–7; *U. S. Pub. Health Eng. Abstracts* **E-637**, 50(1928).—A résumé of the increasing importance of the stream pollution problem, and of the work which is being carried on in order to measure quantitatively the effects of stream self purification and to det. the main factors responsible for it. J. A. K.

Phenol pollution of public water supplies in the Middle West. Herman N. Bundesen. *Water Works* **67**, 240–6(1928).—The work that has been done on the elimination of coke-plant phenol-carrying wastes from public water supplies is reviewed. The 3 methods used for disposing of these wastes are: evapn. by coke quenching, extn. by light oils or benzene and biological absorption in sewage. The phenol wastes produced by the 3 large coke plants in the Calumet Harbor region at the south end of Lake Michigan could be disposed of by either one of the first 2 methods discussed. C. C. Ruchhoff

The double fermentation process with intermediate liming (Hildesheimer process). A contribution to the question of the purification of waste liquors from the sugar factory. E. Nolte. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **3**, 121–33; *Chem. Zentr.* **1927**, II, 1878.—The double fermentation process is suitable when with the existing water supply the water purification is to be increased at a low cost. With a low water flow the putrefactive fermentation process is preferred. Both processes can, however, be recommended under proper surroundings only for the purification of press and diffusion liquors, and not for other waste liquors from the sugar plant. J. S. R.

The biology of activated sludge. R. Kolkwitz. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 1926, 3,

Beiheft. 70–4; *Chem. Zentr.* 1927, II, 1744.—Biological studies carried out at the exptl. plant at Essen with activated sludge suggest a microscopical biological method of control. C. C. Davis

The present status of new biological processes for the purification of waste water with activated sludge. C. Reichle and R. Weldert. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 1926, 3 Beiheft 3–69; *Chem. Zentr.* 1927, II, 1774.—A description of processes in America, England and Germany. C. C. Davis

The occurrence of arsenic fungi on sludge. Else Huth. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 2, 152–4(1926); *Chem. Zentr.* 1927, II, 1744; cf. Tiegs, *C. A.* 22, 4561.—Arsenic fungi are found in the sludge of settling basins of Königsberg and at the surface of the silt of the Frische Haff. C. C. Davis

The transformation of organic and of inorganic substances in general. I. K. Thumm. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 2, 30–2(1926); *Chem. Zentr.* 1927, II, 1744.—As an introduction to a detailed descriptive account of the transformation of the components of waste water by biological processes, the underlying principles are explained. C. C. Davis

Sewage works analyses. F. W. Mohlman. *Proc. 10th Texas Water Works Short School* 1928, 221–32; *U. S. Pub. Health Eng. Abstracts* E-637, 50(1928).—M. points out the necessity of intelligent interpretation of sewage and effluent analyses and suggests that the less informative methods of past years be discarded in favor of more valuable methods now being improved and standardized. The technic of the *biological oxygen demand detn.* and its significance in sewage treatment and stream pollution are discussed. J. A. Kennedy

Calculating the capacity of sludge-digestion tanks. Karl Imhoff. *Am. City* 38, 124–5(1928); *U. S. Pub. Health Eng. Abstracts* E-637a, 52.—Ordinarily with a mean temp. of 59° F., 1 cu. ft. per capita sludge vol. is required. At 50° F., the vol. must be doubled. In the northern part of the U. S. where the winters are more severe, and in towns of less than 5000, the capacity of the sludge tank should be increased. The size depends upon the time interval between draining sludge in the fall and spring. At 59° F., 2 months time is necessary for complete digestion. Addnl. allowance must also be made for wastes likely to retard digestion. J. A. Kennedy

Preliminary results on relation between total acidity, carbon dioxide in solution, organic acids and colloidal material in the course of fresh solids digestion. Willem Rudolfs. *Rept. of the Dept. of Sewage Disposal of the N. J. Agr. Expt. Sta. for the year ending June 30,* 1927, 295–9; *U. S. Pub. Health Eng. Abstracts* E-607b, 46(1928).—For the first 3 days the increase in total acidity was practically all accounted for by the CO_2 in soln. but after 3 days the org. acids began to accumulate rapidly and during the next 10–20 days constituted approx. $^1/_2$ of the total acidity. This would indicate that the decompn. of the carbonaceous substances producing the acids is faster than the decompn. of the acids themselves with the consequent accumulation of the acid material. After 20 days the org. acids decreased rapidly and after 30 days only traces were left. Accumulation of org. acids increased the duration of digestion. Decompn. of nitrogenous substances seemed fastest after the org. acid disappeared. J. A. K.

Filtering materials for sewage work—kind, size and depth. N. T. Veatch, Jr. *Proc. 10th Texas Water Works Short School* 1928, 183–6; *U. S. Pub. Health Eng. Abstracts* E-607d, 49(1928).—Granite, trap rock, quartzite and gravel have proved almost uniformly satisfactory. The size of material used ranges from a grading of $^1/_4$–$2^1/_2$ in. to 2–3 in. With ample head the depth ranges from 6 to 9 ft. for trickling filters, whereas contact beds are usually from 4 to 6 ft. Fine-grained filtering materials usually consist of sand and appear to give the results best of all types of plants. A majority of the beds range from 3 to 4 ft. in depth above the drains. Uniformity of coeff. ranges from 2.5 to 3.5 and effective size from 0.25 to 0.50 mm. in the majority of the plants. J. A. Kennedy

Power gas from sludge. F. C. Vokes and C. B. Townsend. *Water Works* 67, 222(1928).—See *C. A.* 22, 655. C. C. Ruchhoft

Plants for clarifying and purifying sewage. A. Battige. *Apparatebau* 40, 206–9 (1928).—Directions for constructing septic tanks for single dwellings. J. H. M.

Precast concrete simplifies Imhoff tank work. Walter L. Couse. *Eng. News-Record* 101, 430–3(1928).—An illustrated description of the construction of the Imhoff tanks of the new Flint, Mich., sewage works. R. E. Thompson

Seeding new tanks. William Rudolfs. N. J. Agr. Expt. Sta. *Rept. Dept.*

Sewage Disposal 1927, 284–92; *Pub. Health Eng. Abstracts* E-545, 30(1928).—The difficulty sometimes experienced in starting the operation of a new tank was deemed of sufficient importance to warrant lab. expts. to det. a substitute for ripe sludge when the latter was not available. Definite quantities of fresh solids were mixed with ripe sludge, horse manure, cow manure and muck from a creek and results compared with fresh solids seeded with ripe Imhoff sludge. It was found that neither manure nor muck is as effective for seeding as ripe sludge. Muck was about half as good as ripe sludge and cow or horse manure still poorer. If sludge from a pollution stream is available for seeding it should be used. Seeding with lime and horse manure is beneficial but is still inferior to ripe sludge. Addns. of lime to fresh solids when ripe sludge is present for seeding, aids materially in keeping down the floating solids.
C. R. Fellers

Studies on controlling Psychoda alternata Say in sprinkling filters. Daggmar H. Peterson. N. J. Agr. Expt. Sta. *Rept. Dept. Sewage Disposal* 1928, 300–10.—The life cycle of *Psychoda* requiring about 12 days is given. Expts. were made to det. the effectiveness of 50 com. and lab. insecticidal prepns. Aside from flooding the filter bed, no economical method of control for *Psychoda* was found. Oils were more effective than emulsions. *o*-Dichlorobenzene mixed with an equal part of kerosene killed over 90% of the larvae when a l. per sq. ft. was applied. "Flit" at 75 cc. per sq. ft. was equally satisfactory. *p*-Dichlorobenzene in cryst. form caused a high % of deaths when 50 g. per sq. ft. was applied. CS_2 was lethal in an emulsion of 1:100. Continuous application of Cl reduced the no. of larvae but not sufficiently to warrant the expense. Flooding the filter beds greatly decreased the nos. but the larvae were not destroyed.
C. R. Fellers

Emscher basins and separate sludge digestion in the last 22 years. F. Fries. *Gesundh.-Ing.* 51, 577–83, 601–5(1928).—Much improvement has been effected in mech. treatment of city sewage during the last 22 years. All successful installations consist of sep. sedimentation and digestion chambers. With the exception of plants designed to dispose of sewage from individual dwellings, the one-chamber processes have been replaced by sep. sedimentation and digestion. Of the various systems now in use, the Emscher basin is among the best. One of the improvements possible is the simplification of the size and shape of the app. used in gathering the gas produced during the digestion of the sludge. Agitation or mixing of the sludge has been used for some time. In regard to decompn. of the sludge, the temp., the p_H value and the ratio of fresh sludge to digested sludge in the digestion chamber are important. When large digestion chambers with flat bottoms are employed, rakes may be used for the economic removal of the digested sludge from the digestion chambers. In sep. sludge digestion, the best results are obtained when the fresh sludge is admitted at a const. rate. The efficiency is increased by raising the temp. of the digesting sludge. The proportion of the gas obtained to that employed for heating depends upon the size and characteristics of the digestion chamber as well as upon the time of digestion. Economy of operation, when the digesting sludge is warmed, is possible only when the water content is low. Emscher basins, using prewarming of the sludge, have proved very efficient at Essen-Rollenhausen. From this it is concluded that pre-warming of the sludge more than any other factor causes increased efficiency without noteworthy rise in operating costs. The question as to whether the 2 chambers should be built alongside of each other or one on top of the other depends upon local conditions. Views are given which illustrate principal methods of sewage treatment. W. L. D.

Criticism of domestic sewage-treatment plants. Leiner. *Gesundh.-Ing.* 51, 552–5(1928).—Centralized treatment of sewage is much better than treatment in small plants. However, in many instances this method is not available and in such cases, it is better to install small treatment works. Criticism as to the size of decompn. chambers, sepn. of the sludge, velocity of inflowing sewage and construction of small installations is given.
Wayne L. Denman

The design of settling basins for sewage-treatment plants. Karl Imhoff. *Water Works* 67, 229–30(1928).—Settling basins for sewage having a flocculent sludge should be designed according to time and for sewage with a granular sludge according to surface area. Design on the basis of velocity is important in grit chambers.
C. C. Ruchhoft

Novel sewage-treatment methods in small plant. Harry R. Hall. *Public Works* 59, 246–8; *Water Works* 67, 235–9(1928).—The plant described has a capacity of 250,000 gallons per day for a population of 2500 people. A primary settling Imhoff tank and a circular sep. sludge digestion tank are provided. This is unusual for this size of plant, but they were built on account of the saving in construction which was

effected. The plant also includes a secondary settling tank and a sprinkling filter, the stone of which is sloped at a 45° angle on 3 sides instead of being confined by a wall. C. C. RUCHHOFT

Sewage treatment abroad. WILLEM RUDOLFS. *Public Works* **59**, 265–8, 310–12 (1928).—This paper describes briefly new grease removers, submerged contact aerators, several new types of aeration tanks, new Imhoff tanks and gas collectors which have been developed in Holland and Germany. C. C. RUCHHOFT

Sewage works designed to meet needs of automobile town. WALTER R. DRURY. *Eng. News-Record* **101**, 357–8(1928).—A description of the recently completed sewage works of Flint, Mich., consisting of radial-flow Imhoff tanks and sludge-drying beds. Trickling filters, secondary sedimentation tanks and chlorinating equipment will be added in the near future. The city is sewered on the separate plan and the sewage is very strong, contg. oil and grease and other trade wastes. The sewage flow is 10$^1/_2$ million gallons per day from a connected population of 120,000. There are 4 Imhoff tanks designed for a capacity of 4 million gallons per day each, the sludge capacity being equiv. to 2.75 cu ft. per capita. The sludge-drying area provided is equiv. to 0.75 sq. ft. per capita for a population of 160,000. R. E. THOMPSON

Activated-sludge disposal plants at Charlotte, N. C. E. G. MCCONNELL. *Public Works* **59**, 268–74(1928).—The Irwin Creek plant, which is described, includes coarse bar screens, 6 aerating and settling tanks with a rated capacity of one million gallons each, 2 conditioning tanks and 2 Oliver filters. Each coupled aerating and settling tank is a complete unit. The settling tanks are equipped with Link Belt type sludge collectors. $FeCl_3$ and alum are used as conditioning chemicals, about 8 lb. of the former being used per 1000 gallons under av. conditions. About 7 tons of 80% moisture filter cake are produced daily and have been spread upon the grounds adjoining the plant, plowed under and planted without appreciable odors. C. C. RUCHHOFT

Sewage treatment in the region of Chicago. PAUL HANSEN. *Proc. 10th Texas Water Works School* **1928**, 210–21; *U. S. Pub. Health Eng. Abstracts* **E-637**, 50(1928).—The work being done in sewage treatment, both by the city of Chicago and in its various Sanitary Districts is summarized. General design data are given for the North Side, Des Plaines, West Side and Calumet plants in Chicago, as well as those for *Indianapolis, Milwaukee, Elgin, Springfield, Decatur, Urbana-Champaign, Hinsdale* and *Wheaton* Sanitary Districts. J. A. KENNEDY

Industrial waste work of the sanitary district of Chicago. F. W. MOHLMAN. *Water Works* **67**, 163–6(1928).—The biological O demand of domestic sewage per capita per 24 hrs. at 20° has been detd. as 0.167 lb., 0.220 lb. and 0.244 lb. for 5, 10 and 20 days, resp. These factors are used to convert industrial wastes of an org. nature into terms of equiv. population. Treatment of the 3 principal wastes including *packinghouse, tannery* and *corn products*, which were equiv. to a population of 1,537,000 in 1922, have been studied extensively in exptl. treatment plants (testing stations). The activated-sludge method was found satisfactory for packinghouse wastes. Biological treatment proved uneconomical for tannery wastes and screening and sedimentation proved most successful. Neither settling nor the activated-sludge method proved satisfactory for corn products wastes while a 7.5-ft. deep trickling filter gave satisfactory effluents at a rate of 700,000 gallons per acre per day. By a recirculation of the waste waters from the starch and gluten settlers and a removal by concn. of feed material, the population equiv. of the corn products wastes was reduced from 380,000 in 1922 to 75,000 at present. About 8 to 10 tons of H_2SO_4 from the Sherwin Williams Paint Co. is being discharged daily in the sewers entering the Calumet Treatment Works which was receiving about 41 million gallons of sewage per day. This waste reduced the p_H and the bacterial content of the raw sewage and produced a harmful effect in the plant, especially the activated-sludge tanks. Storage tanks for equalizing the flow of acid are being installed. C. C. RUCHHOFT

Sewage-disposal plant construction at Fond du Lac, Wisconsin. L. R. HOWSON. *Water Works* **67**, 232–3(1928).—The new plant with a capacity of 4 m. g. d. includes coarse screens and pumping station, settling tanks with Dorr clarifier equipment, sludge-digestion tanks with Dorr digestor equipment, sludge-drying beds, sprinkling filters and an outfall into Lake Winnebago. C. C. RUCHHOFT

The design of small sewage-treatment works at Gaithersburg, Md. HARRY R. HALL. *Water Works* **67**, 235–9(1928); *U. S. Pub. Health Eng. Abstracts* **E-637**, 51 (1928).—This is an account of a painstaking study to fit a high grade of treatment (sprinkling filter) to a town of 2000 people by designing economically with easiest extension of the plant. A full description is given. J. A. KENNEDY

Recent sewage studies at Houston, Texas. G. L. FUGATE AND W. S. STANLEY.

Proc. 10th. Texas Water Works Short School **1928,** 199–201; *U. S. Pub. Health Eng. Abstracts* **E-607d,** 47–8(1928).—When the activated sludge in the lagoons falls below p_H 7.0, crusting of the surface and highly offensive odors result. Persistent stirring and hosing alleviate the condition somewhat. Expts. on dewatering and drying the sludge, instead of lagooning, finally indicated that a vacuum disk filter would be the most economically efficient method of handling the sludge. Activated sludge should be conditioned to a p_H of 5.4, well aerated, and with as little agitation as possible after the addn. of the conditioner, for successful filtration. If the moisture content was kept below 85%, no difficulty was presented in drying the cake obtained after filtration.
J. A. KENNEDY

The Jacksonville, Texas, sewage-disposal plant. H. L. THACKWELL. *Proc. 10th Texas Water Works Short School* **1928,** 204–7; *U. S. Pub. Health Eng. Abstracts* **E-607d,** 48(1928).—This plant treats 400,000 gals. of domestic sewage per 24 hrs. The units comprise a combined grit and screen chamber above ground; primary settling tanks with 1-hr. retention; and a contact aerator with 1-hr. retention, employing brush-wood media on a Monel metal hammock over filtros plates in precast concrete containers. Air is applied in this last unit at the rate of 0.25 cu. ft. per gal. of sewage. The coagulated sewage from this activation plant is then passed into a secondary settling tank for a 15-min. detention period and after rising through a gravel filter supported on a Monel metal screen, the effluent falls over a step aerator into a dosing tank. The dosing chamber sprays the sewage under a $9^1/_2$-ft. head to a trickling filter bed rated at 500,000 gals. per acre ft. The bed is 6 in. deep with perforated tile under-drains. The effluent is chlorinated and then run through a humus tank of the Imhoff type with a 20-min. retention period. Sludge is cared for in a covered concrete sludge tank arranged for digestion. The glassed-over sludge-drying bed is provided for drying and removal of digested sludges. The total cost was $35,000. The cost of operation is about $22 p. m. g. which includes pumping costs of 2 lift stations.
J. A. KENNEDY

Experience with the construction and operation of the purification plant at Kettwig. MAHR. *Technischen Gemeindeblatt* **31,** 15 pp.(1928); *U. S. Pub. Health Eng. Abstracts* **E-637a,** 52(1928).—Kettwig is a small town of about 7000 on the lower Ruhr. The sewage treated contains in addn. to normal constituents, large amts. of wastes from spinning mills, cloth factories (heavily polluted with dyes), and wool-washing plants. The process includes circulation of sewage on long, shallow sand beds, Imhoff-tank treatment and sludge-drying beds. A complete description of the plant construction and methods employed is given. J. A. KENNEDY

Luton (England) new sewage pumping station. J. W. TOMLINSON. *Munic. Eng. Sanit. Record* **81,** 338(1928).—A brief description of the equipment of the plant such as the kinds of engines, pumps, boilers, etc., is given. C. H. BADGER

Schenectady sewage-plant operation. MORRIS M. COHEN. *Public Works* **59,** 223–5(1928).—During 1927 a reduction in the amt. of hosing to the gas vent scum was accompanied by a reduction in the foaming, a better texture of the sludge withdrawn and a reduction in the cost of labor at the plant. In the spring as the level of the scum built down to the level of the slots and solids belched through the slots the tanks were rested until the slots became clear. Units were rotated in non-operation until May. Parallel operation of tanks with and without chlorination (4 p. p. m.) of the raw sewage showed no deleterious effect. The trickling filters operated well. They were flooded 8 times for *Psychoda* control. An interesting attempt was made to distribute *Archorutus viatrius* after flooding. These insects were floated to the surface during flooding, skimmed off and stored in metal baskets during the period of flooding and then put into the siphon chambers for distribution over the bed area.
C. C. RUCHHOFT

Waco's new activated-sludge disposal plant. C. C. HAYS. *Proc. 10th Texas Water Works Short School* **1928,** 207–9; *U. S. Pub. Health Eng. Abstracts* **E-637,** 50 (1928).—This plant of 4 m. g. d. capacity comprises bar screens, grit chambers, presedimentation tanks with mech. sludge-removal equipment, aeration tanks of the Manchester design, and settling tanks with the mech. sludge-removal equipment. Sludge is disposed of in adjoining lagoons. Operation costs are $11.90 p. m. g.
J. A. KENNEDY

The treatment and utilization of vegetable refuse. P. S. WOOLEY. *Munic. Eng. Sanit. Record* **81,** 264–5(1928).—The incoming vegetable refuse is mechanically pulverized. The pulped mass is agitated in a sepg. device where stones, crockery, iron, etc., are removed by gravity. The surplus water is screened through fine copper gauze on a slowly revolving drum. Heavy rolls next break down the cell matter and

free the contained water. It passes on to a traveling felt where the water is squeezed out between other heavy rolls. The residue is dried; a salable and hygienic product is thus produced. C. H. BADGER

Sewerage and sewage disposal as affecting public health. ERIC RIDEAL AND H. C. H. SHENTON. *Munic. Eng. Sanit. Record* **81**, 368–9(1928).—Sewage works should deliver 0.18 to 0.27 lb. of easily assimilable O per capita per diem at min. expense. Since all sewage undoubtedly contains pathogenic bacteria, *e. g.*, *B. tuberculosis* the air near sewer overflows and lagoons of septic sewage is potentially dangerous. Bacteria are set free by evapn. of droplets and through splashing or bursting of gas bubbles from septic sewage. These may be kept afloat for days by air currents because of their lightness and large surface area. Sewage also contains an enormous no. of organisms likely to cause food spoilage. The oscillation of a water piston up and down tidal rivers or the rate of displacement of sewage effluent by fresh and sea water dets. whether a menace will be caused or not. Spores of fungi and molds develop into mature organisms on food material available for them in many discharges and make the lower regions of rivers unsightly for miles and possibly affect fish life. C. H. BADGER

Chemical determinations in the field of air hygiene. I. W. LIESEGANG. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **3**, 4–10; *Chem. Zentr.* **1927**, II, 1990.—Detns. of the sulfate in pine needles and in snow furnishes a starting point towards estg. the extent of contamination of air by flue gas. C. C. DAVIS

Effect of antiseptic sprays on the bacterial content of air. S. R. DOUGLAS, LEONARD HILL AND WILSON SMITH. *J. Ind. Hyg.* **10**, 219–26(1928).—Expts. on two antiseptic sprays suitable for use in places of public assembly or in crowded workrooms show a distinct bactericidal effect on *Bacillus coli communis* suspended in the atmosphere. C. M. SALLS

Carbon monoxide. D. STAVORINUS. Westergasfabriek, Amsterdam. *Het Gas* **48**, 338–41(1928).—From literature data it is shown that CO liberation by escaping illuminating gas is very insignificant as compared with the pollution of the atm. by CO from internal-combustion engines. B. J. C. VAN DER HOEVEN

Investigation of atmospheric pollution. ANON. *Dept. Sci. Ind. Research (Brit).* **1927**, 13th Rept., 54 pp.—Observations in the year ending March 31, 1927, on 79 deposit gages and 11 automatic filters maintained at 34 stations in England are reported, and the deposit of impurity at 80 different stations is considered. A classification is made according to standards of increasing quantity of deposit. During the 13-year period an improvement was noted at stations where there was only moderate pollution; but at stations where the pollution was greatest, little improvement was noted. Carbonaceous or sooty matter made its highest deposit at Newcastle-on-Tyne, the lowest being at Rothamsted. The highest deposit of sulfates was at Burnley, the lowest at Southport (Hesketh Park). There is a wide variation in the compn. of deposits, depending upon both season and location. The increasing use of gas partly accounts for the reduction of sulfates noted during recent years. The hourly variation in suspended smoky matter in the air and the effects of the coal stoppage of 1926, are demonstrated graphically. An account of the salt haze at Norfolk is given and a method of trapping it for examn. is described. A curve demonstrates the fact that nearly the whole of the ultra-violet radiation of the sun is cut off by a comparatively small amt. of smoke in the air. C. M. SALLS

Air investigations to determine smoke damage. M. BAMBERGER AND J. NUSSBAUM. Technische Hochschule, Vienna. *Z. angew. Chem.* **41**, 22–6(1928).—To det. the av. SO_2 content of air over a long period of time a 1.5-l. wide-mouth bottle was wrapped in absorbent cotton wet with a soln. contg. 1 part K_2CO_3, 1 part H_2O and 2 parts (all by wt.) of glycerol (sp. gr. 1.26), and then placed in a glass dish to catch the excess of soln. A wooden stopper in the bottle supported a protective shade for the app., and through the stopper a funnel passed into the bottle (which contained some K_2CO_3), thus converting it into a rain-gage. The whole app. was fastened securely to a support, say on a roof. After an exposure of some months the cotton was washed off thoroughly with H_2O, the soln. oxidized with Br-water, concd. by evapn., acidulated with HCl, and then pptd. with $BaCl_2$. Results obtained with a number of these pieces of app. distributed over a region under investigation for smoke damage gave surprizingly clear indications as to the probable distribution of the SO_2, *i. e.*, of the smoke. By observing the form and extent of the smoke cloud it was concluded that its height above the ground remained fairly uniform for a given state of the weather, but rose or fell greatly with changes in the weather. The av. values of the SO_2 content of air at a given place depends upon the length of time the smoke is present. A formula

$S = a.\dfrac{b - H}{D}$, is proposed for connecting the SO_2 content of the air (S) with the altitude above sea-level (H) and distance from the source (D) of smoke; a represents a const. depending upon the duration of the investigation, frequency and strength of the smoke, size of the impregnated fabric, quantity of smoke emitted, weather conditions, etc., and b is a height depending chiefly upon weather conditions. The const. a applies only for a given wind direction; if all the a-values are taken as vectors with respect to the source of the smoke there is obtained the so-called "ellipse of damage"—a figure that varies from this form considerably with conditions of the terrain. By treating graphically observations on SO_2 made at 12 stations over a 100-day period a curve was obtained that agreed well with calcns. based upon the formula above, the product DS is a const., showing that the concn. of SO_2 varies inversely with the distance from the source. It is claimed that this proves the usefulness of this form of "roof apparatus" in detg. smoke distribution over a given area. Formulas are proposed for detg. the amt. of SO_2 from each of 2 sources passing over a given station, but with wind currents such computations are valueless. A law connecting the amt. of damage with SO_2 content of the air is as yet unknown. The methods proposed are not to replace other ways for detg. smoke damage, but are to contribute their own share in solving such problems. W. C. Ebaugh

Chemical control of ventilation at the Holland Tunnel. S. H. Katz and H. W. Frevert. *Ind. Eng. Chem.* 20, 564–70(1928).—Concns. of CO are controlled through 14 continuous, automatic CO recorders. Tunnel ventilation is increased only when recorders show increasing concn. of CO, thus effecting a saving of power. On one day when 51,750 cars passed through the tunnel in 24 hrs. the highest CO concn. was 3.2 p. p. t. t. and the max. average for one hour was 2.2 p. p. t. t. On a normal business day only one-half of the ventilating capacity was used and max. average during any one hour was only 0.7 p. p. t. t. C. M. Salls

The use of chloropicrin for disinfection and disinfestation of clothing and dwellings. O. Galler and T. Sassiquine. *Rev. Microbiol. Epidem.* 6, 275–9(1927); *Bull. Hyg.* 3, 500(1928).—Besides those present bugs and bacteria were placed in most inaccessible places and the house was sealed. Chloropicrin was injected into the house, 5 to 10 cc. per cu. m. After 48 hrs. all bacterial cultures and bugs were killed. G. R. G.

Is Paris green a better larvacide for anopheles than naphtha or petroleum? O. Hermann, J. Kolossow and N. Lipin. *Arch. Schiffs-Tropen Hyg.* 32, 140–3(1928).—Paris green may be used only when naphtha or petroleum is inapplicable. F. K.

Malaria control for cities and towns. L. L. Williams, Jr. *Va. Med. Monthly* 55, No. 3, 198–200(1928); *Pub. Health Eng. Abstracts* E-576c, 18(1928).—There are but 2 certain measures of control for malaria, namely, adequate screening and the control of the breeding of the anopheles mosquito. Expts. prove definitely that screening, if thoroughly done, is efficacious. Drainage is the most effective method of controlling the production of mosquitoes. Undrainable places must receive a weekly dose of oil to prevent breeding during the summer season. Where anopheles only are to be stopped, it is only necessary to det. their breeding places and control them by drainage or oil. Paris green mixed with road dust (1 to 99) and cast on the windward side of a breeding area is effective. The rate of application should be 1 lb. per acre. Since *Anopheles quadrimaculatus* breeds only in water with no apparent current, quiet water ponds, pools and sluggish brooks within a mile from the town or city, must be drained or be treated with Paris green once a week. C. R. Fellers

The process of digestion in tsetse flies. H. M. O. Lester and Ll. Lloyd. *Bull. Entomol. Research* 19, 39–60(1928).—The salivary glands of the tsetse flies (*Glossina mortisans; G. tachinoides*) contain a powerful anticoagulin, which delays the clotting of the blood of mammals, birds, reptiles and batrachians. Its purpose is to prevent clotting and blood coagulation in the crop of the flies. The proventriculus and the first third of the mesenteron take no part in blood coagulation but contain the anticoagulin, which is derived from the salivary secretion. The posterior part of the mesenteron contains a powerful coagulin which neutralizes the effect of the anticoagulin and liquifies the blood food in this region. Both enzymes have the ordinary properties of enzymes, the salivary enzyme being the more stable. When mixed they probably unite to form some inactive compd. The salivary enzyme is probably so combined with some substance in the blood that its neutralization by the coagulant enzyme is delayed. It seems to take part in the formation of thrombin and to be akin to antikinase. The mesenteric enzyme (coagulin) does not affect blood from which Ca has been removed; therefore it is not like thrombin. It probably also influences the first phase of clotting, behaving like kinase. The mechanism of draining of the blood

meal is described. The Malpighian tubules function properly only when the fluid food has an osmotic pressure near that of blood. A large meal of water generally kills the fly. C. H. RICHARDSON

An examination of the efficacy of arsenical solutions in the reclamation of tsetse areas. H. L. DUKE, G. N. HALL AND E. C. HADDON. Uganda Protectorate, Africa. *Bull. Entomol. Research* **19**, 7–21(1928).—The tsetse fly (*Glossina palpalis*) can take up a toxic dose of As from an As-impregnated area by means of the proboscis. It can also remove a toxic dose from a wet or dry impermeable surface. The chance of obtaining a poisonous dose of As from the skin of a dipped animal is much less than from other types of treated surfaces. The risk is greater from the wet than from the dry skin. The use of "dummy" animals impregnated with As is discussed and seems of questionable value. Experiments to determine the effect of dipping with As-contg. solns. to rid infected animals of trypanosomiasis were inconclusive. This treatment probably tends to develop As-fast strains. Dipping with As solns. leads to a general improvement in the condition of the animal. C. H. RICHARDSON

Observations on the thermal death points of the blow-fly at different relative humidities. M. V. F. BEATTIE. London School Hyg. and Trop Med. *Bull. Ent. Research* **18**, 397–403(1928).—The thermal death point of the blow-fly (*Calliphora erythrocephala*) is definitely influenced by humidity, satd. and dry air lowering it. Relative humidities of 60–80% were more favorable and 70% was found to be an optimum point. Death in satd. air was due to the inability of the fly to regulate its body heat by evapn. Death in dry air was not explained. C. H. RICHARDSON

Mosquito breeding and malaria in relation to the nitrogen cycle. K. B. WILLIAMSON. *Bull. Entomol. Research* **18**, 433–9(1928).—The following conditions are important: (1) efficient oxidation of the products of protein lysis in the water; (2) the ratio between the oxidized and ammoniacal N; (3) the amt. of dissolved O_2 in the water; (4) presence of microörganisms which serve as food or produce disease. The p_H of the water is not of great importance. C. H. RICHARDSON

The reaction of the breeding places of Anopheles in Macedonia. (MISS) H. RUSSELL. *Bull. Entomol. Research* **18**, 155–8(1928).—The common anopheline mosquitoes of Macedonia (*Anopheles bifurcatus, A. superpictus, A. maculipennis*) breed in alk. water ranging from p_H 8 to 9.5. The local culicine mosquitoes are not so selective, being found in water ranging from p_H 6.5 to 10. The p_H of the water is often an index of the presence of anopheline larvae and so is of practical value to the anti-malaria worker. The geological formation of Macedonia is such that a study of the reaction of its natural water will be of great interest to students of mosquitoes and to sanitary engineers. C. H. RICHARDSON

Determination of H_2SO_4 in water (DOBROWSKY) **7**. Classification of saturated salt lakes (KROTOV) **8**. External corrosion of Cu and brass service pipe (LOGAN, EWING) **9**. Paralana hot spring (MAWSON) **8**. The preparation and testing of food gelatin for the bacteriological investigation of water (BEGER) **11C**. The disposal of effluents from sugar-beet factories (UNDERWOOD) **28**. Catalytic action of mineral waters (GAISSER) **2**. Metal-metal oxide electrodes (WATSON) **2**. Mixing solids with liquids such as in water purification (U. S. pat. 1,686,076) **13**.

Venturi and valve construction for controlling the flow in water-purification systems. MILTON F. STEIN (to General Zeolite Co.). U. S. 1,685,205, Sept. 25.

Mixing apparatus for purifying water by treating it with chemicals. WILSON EVANS (to National Aluminate Corp.). U. S. 1,686,078, Oct. 2.

Apparatus for purifying water by chemical treatment, settling, etc. WALTER H GREEN (to General Zeolite Co.). U. S. 1,684,822, Sept. 18.

Degasification of water. JOHN C. HOVEMAN, CHARLES R. HOVEMAN and HENRI L. F. MOUZET. Fr. 635,388, June 1, 1927. Water for certain industrial uses is submitted in the form of a fine spray to a high vacuum.

Apparatus for softening water by zeolitic material. WILLIAM J. KENNEY (to Zeolite Engineering Co.). U. S. 1,685,816 and 1,685,817, Oct. 2. Structural features U. S. 1,685,818 (not assigned when issued) also relates to a combined filter and upflow water-softening app.

Base-exchange silicates. ESKEL NORDELL (to Permutit Co.). U. S. 1,687,036, Oct. 9. Reaction is effected between Al acetate or other suitable sol. Al salt of an org. acid and a soln. of an alkali metal silicate, the gel product is partially dried, leached, broken up and screened to size for use, *e. g.*, in *softening water.*

Treating evaporator water containing scale-forming impurities. GEORGE W

SMITH (to John M. Hopwood). U. S. 1,686,715, Oct. 9. Impurities which would tend to soften the scale are removed from water, *e. g.*, by filtration to sep. suspended $CaCO_3$, etc., and the water is evapd. to such a concn. as to cause the formation of a hard scale on the heating surfaces of the evaporator; these surfaces, which may be in the form of helical brass pipe coils are periodically deformed, *e. g.*, by increase of steam pressure, to crack off the scale. An app. is described.

Use of iron silicate as a filtering medium for hot alkaline boiler waters. RALPH E. HALL (to John M. Hopwood). U. S. 1,686,558, Oct. 9. An app. is described.

Preventing corrosion and incrustation in boilers. SOC. DES PERFECTIONNEMENTS APPLIQUÉS A L'INDUSTRIE. Brit. 285,057, Feb. 10, 1927. An emulsion is formed from vegetable seed cake such as linseed cake, for use in preventing incrustation or corrosion.

Preventing incrustation in boilers. H. BREYER. Brit. 284,629, Feb., 1927. An incrustation preventive is prepd. from myrobolan, quebracho, $NaHCO_3$ and NaF.

Treating polluted acid wastes. JOHN T. TRAVERS (to Travers-Lewis Process Corp.). U. S. 1,685,300, Sept. 25. Acid wastes such as those from *mines or steel mills* are passed through porous $CaCO_3$ and maintained in contact with the $CaCO_3$ for 2–5 min. in order to avoid deposition of $Fe(OH)_3$ on the $CaCO_3$. U. S. 1,685,301 specifies the use of travertine or a $CaCO_3$ material of similar porosity. Cf. *C. A.* **22,** 2632.

Treating sewage and other waste products. AKTIESELSKABET DANSK GAERINGS INDUSTRI. Brit. 284,267, Jan. 26, 1927. Waste waters from *distilleries* and from *yeast, sugar* and other *factories* utilizing molasses are purified by the action of aerobic or anaerobic betaine-destroying microörganisms which may convert the betaine and its derivs. into CO_2, NH_3 and formic acid. In a second stage, the org. acids such as formic acid may be removed by bacterial decompn. The waste water contg. humus may also be treated with organisms which may be used in the first or second stage of the process. Albuminous substances may be removed by albumin-decompg. bacilli or by filtering and yeast cells may be removed mechanically or by plasmolysis or by heating and use of albumin-destroying microörganisms. Various details and a diagrammatic plan of app. are given.

Apparatus for treating sewage with disinfectants in "sanitary closets." EPHRAIM L. JACKSON. U. S. 1,687,336, Oct. 9.

Treating garbage. REVERE P. KINKLE. U. S. 1,684,448, Sept. 18. Garbage is subjected to the drying action of a current of hot gases and NH_3 is recovered from the gases. The dried garbage is burned and the heat produced is utilized for the drying and NH_3-recovery operations.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Monolithic soil profiles. J. E. CHAPMAN. N. Dakota Expt. Sta. *Science* **68,** 299(1928).—A rapid method of taking monolithic soil profiles to a depth of 40 in. in stone-free soils is described. E. F. SNYDER

Do soil samples become more acid upon drying? WIDAR BRENNER. *Z. Pflanzenernähr. Düngung. Bodenk.* **11A,** 141–4(1928).—From a review of the literature on the influence of drying on the H-ion concn. of soil suspensions and exts., B. concludes that drying does not significantly change the p_H value of soils. R. M. BARNETTE

The laboratory for soil research. J. HUDIG AND C. W. G. HETTERSCHIJ. *Chem. Weekblad* **25,** 501–6(1928).—Descriptive. B. J. C. VAN DER HOEVEN

Theoretical viewpoints on the analyses of soil for plant nutrients. S. GERICKE. Oldenburg i. O. *Z. Pflanzenernähr. Düngung. Bodenk.* **11A,** 144–50(1928).—A critique giving advantages and disadvantages of the different methods used in arriving at the plant nutrient content of the soil—*i. e.*, Mitscherlich mathematical formulation, Neubaurer plant method and chem. methods. R. M. BARNETTE

Making a correct mechanical analysis of soils in fifteen minutes. GEORGE J. BOUYOUCOS. Mich. Agr. Expt. Sta. *Science* **67,** 587–8(1928).—A brief discussion of the points of agreement and disagreement between the hydrometer and mech. analysis methods of soil analysis. The criticisms of Joseph and Keen regarding the hydrometer method are not justified. E. F. SNYDER

Formula for the control of the apparatus used for the mechanical analysis of the soil. MIECZYSLAW JANOWSKI. *Rocsniki Nauk Rolnicsych I Lesnych* **18,** 31–7; *Chem. Zentr.* **1927, II,** 1885.—A formula is given for calcg. the height of water in the piezometer

tube of the hydraulic app. using an upward flowing water current for the mech. analysis of the soil. G. SCHWOCH

The relation between the mechanical composition and the hygroscopicity of a soil. FRITZ GIESECKE. Göttingen. *J. Landw.* **76**, 33–40(1928); cf. *C. A.* **22**, 2633.—No relation could be found between the hygroscopic coeff. and the clay content or the ratio of clay to fine silt. E. F. SNYDER

Extraction of soils by the hydrochloric acid method. E. BLANCK AND A. RIESER. *J. Landw.* **76**, 25–31(1928).—Three modifications of the method proposed by the International Commission were compared with the Commission's method and differences observed in the subsequent analyses. The method of prepn. of the soil for analysis also affected the proportion dissolved by HCl. E. F. SNYDER

Comparison between soil examinations by the seedling method and the method of Mitscherlich. H. NEUBAUER, W. BONEWITZ AND A. SCHOTTMÜLLER. Staatlichen Landw. Versuchsanstalt, Dresden. *Landw. Versuchs. Sta.* **107**, 131–42(1928).—The comparison of results of soil examns. by the 2 methods depending upon entirely different principles offers valuable suggestions for further work. One cannot, however, conclude without further work, on a failure of the seedling method, if their results in certain cases do not agree sufficiently with those by Mitscherlich. E. F. SNYDER

Soil acidity methods as applied to soil survey work. S. D. CONNER, M. F. MORGAN AND G. W. CONREY. *J. Am. Soc. Agron.* **20**, 881–92(1928).—A brief discussion of soil acidity and crop growth, soil-acidity methods and their value in soil survey work. E. F. SNYDER

Reaction of South Australia soils. JAMES A. PRESCOTT. Univ. Adelaide. *Trans. Proc. Roy. Soc. S. Australia* **51**, 287–90(1927).—The soil reactions were detd. by the technic of Biilman and Torborg-Jensen (cf. *C. A.* **22**, 1644). The results are tabulated in a form which brings out the facts as to locality, rainfall and soil reaction. . There is a limit on the acid side which is governed by rainfall conditions. Generally, acid soils do not occur with a rainfall much less than 20 in. The reaction of calcite in equil. with the CO_2 of the atm. is about p_H 8.4, which, with few exceptions, is approx. the limit of alky. of the surface soils. Many of the subsoils have a high alky. with an extreme limit of p_H 9.3. Analyses, using the method of base exchange, show that these highly alk. soils have their reactive fractions partially satd. with Na. Examn. of the aq. exts. for salt content further indicates the presence of free carbonate ions. L. W. R.

A schematic soil map of European Russia, 1927. L. J. PRASSOLOV. *Ernähr. Pflanze* **24**, 348–51(1928). LAWRENCE P. MILLER

The so-called "Tepetate" soil in Mexico. H. HELLMERS. Preuss. Geol. Landesanstalt, Berlin. *Z. Pflanzenernähr. Düngung. Bodenk.* **11A**, 112–4(1928).—The chem., phys. and microscopic examn. of a "Tepetate" soil from Hacienda Amalúcan, Mex., showed that this soil must have been formed primarily from fine volcanic sand. R. M. BARNETTE

The reaction of the soils of Württemberg. M. v. WRANGELL AND K. W. MÜLLER. *Jahresb. Ver. Vaterl. Naturk. Württemberg* **83**, 112–45(1927).—For detg. p_H 40 g. soil was mixed with 100 cc. H_2O, allowed to stand with occasional shaking for 12 hrs., and filtered, detns. being made immediately with nitrophenol indicators. The data are tabulated with respect to geological formations and soil texture. About 16% of the soils showed $p_H > 7$, 74% 6.5–7.0, 8% 6.0–6.4, and 2% $p_H < 6$. The p_H varied from month to month, the max. difference, 1.6 p_H unit, being shown by a sandy loam. The presence or absence of single plant species is not a safe guide for judging reaction, as the supposedly acid-soil plant, sorrel, was found growing with neutral-soil clovers in a soil of p_H 6.7. A loam soil of original p_H 6.5 was brought to various values with H_2SO_4 and CaO, and used for growing 8 crops. The optimum yields were obtained for: oats and rye at p_H 5–6; barley, wheat, peas and red clover, p_H 6–7; sugar beets and corn, p_H 8 (falling to 7.5 toward the end of the expt.) Suggestions of bimodal curves were obtained with some of these. Except for isolated cases injury by soil acids and alkalies is not to be expected in this province. E. T. WHERRY

Chemical soil analysis and molecular proportion. K. UTESCHER. Geologischen Landesanstalt, Berlin. *Z. Pflanzenernähr. Düngung. Bodenk.* **11A**, 265–81(1928).—As the mol. proportions of the SiO_2: Al_2O_3: bases in clay as detd. by the methods used at the Geologischen Landesanstalt in Berlin have been criticized by numerous investigators who failed to obtain the mol proportions as found at the Berlin institute, U. has made a critical examn. of the methods used by other workers and shows that the method of making the HCl extn. (*i. e.*, heating on water bath or with reflux condenser) makes a great difference in the calcn. of the mol. proportions and gives results which are not comparable with those obtained in the Berlin institute. The methods used at the

Preuss. Geologischen Landesanstalt are definitely and accurately described so that they may be available to other workers. R. M. BARNETTE

The chemical determination of soil fertility. K. BAMBERG. Universität, Riga. *Z. Pflanzenernähr. Düngung Bodenk.* 11A, 115–41(1928); cf. *C. A.* 22, 294.—The soly. of soil phosphates, Al_2O_3, Fe_2O_3 and org. matter in HNO_3 and citric acid of varying concns. was increased by drying. The soly. of $Ca_3(PO_4)_2$ (Kahlbaum) and $AlPO_4$ (Kahlbaum) was greater in HNO_3 than in citric acid at the same H-ion concn. $FePO_4$ (Merck) was more sol. in citric acid. From a comparison of the Mitscherlich method, the Neubauer plant method and the soly. of soil P_2O_5 in HNO_3 (adjustment of soils to an end p_H of 2) and in neutral ammonium citrate, it is maintained that in soils with a low P_2O_5 content all three methods give a satisfactory agreement, but in soils with a high P_2O_5 content the Neubauer method gives low results and that better agreement is obtained between the Mitscherlich and the chem. methods. The soly. of soil K_2O is dependent upon the end p_H which is obtained with the different acids. The anion of the acid does not influence greatly the soly. of the soil K_2O; however, the H-ion concn. of the original soil does influence the results. A comparison of the Mitscherlich figures with those obtained by the Neubauer plant method and chem. methods (K_2O sol. in HNO_3 at an end p_H 2, or in 1 or 2% ammonium citrate, or 2% ammonium acetate) shows that the Neubauer method agrees closely with the chem. methods, while the Mitscherlich procedure gives low results. From a comparison of field observations with chem. analyses (soly. of soil K_2O and P_2O_5 in acid) it is maintained that valuable information relative to the response of soils to applications of fertilizer salts can be obtained. R. M. BARNETTE

Acidity of moorland soils. B. TACKE, P. ARND, W. SIEMERS AND J. SAFFRON. *Landw. Jahrb.* 65, 66–103(1927); *Biederman's Zentr.* 57, 7–8(1928).—The Tacke-Süchting method shows no exchange acidity in moorland soils. Results indicate a decompn. of neutral salts by soils rich in org. matter. Liming effects a 50% neutral salt decompn. Decompn. is influenced by the nature of both ions. The resistance to decompn. is of the following order, chlorides, nitrates and sulfates. G. R. G.

The exchange acidity of soils formed by the weathering of igneous rocks. RUDOLF PUERCKHAUER. Hochschule Weihenstephan. *Z. Pflanzenernähr. Düngung Bodenk.* 11A, 359–98(1928).—In this investigation, all the soils formed from the weathering of igneous rocks were acid under uncultivated conditions. Under the influence of cultivation and culture the top soil showed a tendency to be less acid than the uncultivated conditions, though the av. of a large no. of detns. on different soils showed that this tendency was not great. The av. p_H value of KCl exts. was 4.91 ± 0.572. The av. p_H value of the subsoil at different depths of sampling was almost the same for the different depths. An av. of 508 detns. was p_H 4.48 ± 0.25. Despite this fact, in individual cases certain factors changing the acid character of the subsoil could be detected. The reaction of these soils is not influenced to any great degree by their orthographic position, the depth of the weathered layer, nor the stone or clay content. These soils under a forest growth show a greatly increased acidity even in the lower depths. This increased acidity in the lower depths persists long after the soils have been brought into culture. A difference in reaction due to the utilization of the soils for meadows or culture could not be detected. Differences which were encountered were founded in the different fertilizer practices which were followed. Correct use of the soil for pasture seemed to have a favorable influence on the reaction. Utilization of these soils for gardens leads to a significant change in the reaction of even the lower depths toward the alk. side. Physiologically acid fertilizers on these soils played a very subordinate role in changing the reaction. Lime changed the reaction significantly as did also stable manures. The buffer content of these soils is low. The garden soils had the highest content of buffering materials. Clover grew satisfactorily on these soils even under p_H 4.5. R. M. BARNETTE

Acid properties of artificial and soil permutites from which the bases have been removed. W. U. BEHRENS. Univ. Koenigsberg i. Pr. *Z. Pflanzenernähr. Düngung Bodenk.* 11A, 281–7(1928).—From a study of a permutite (Permutit A.-G., Berlin), treated with CH_3COOH to remove the Na together with the untreated Na permutite and combinations of the 2 permutites in their reaction with different concns. of KCl, B. concludes that the acid permutite may be considered an acid permutitic acid as it contains H, can split off H ion and shows a titrable acidity. The H-ion concns. of mixts. of Na permutite and permutitic acid were measured and it was found that the p_H value depends upon the electrolyte content (in this case KCl) of the soln. The permutitic acid has about the same dissocn. const. as carbonic acid. The corresponding acid combinations of the soil are generally somewhat stronger than that of the permutite.

The phenomena of treating a permutite or soil with a neutral salt soln. may be explained on the basis of the law of mass action and soly. laws without the use of the "adsorption" ideas. R. M. Barnette

Adsorption phenomena in acid soils. Walter Hillkowitz. Landw. Hochschule, Bohr-Poppelsdorf. *Z. Pflanzenernähr. Düngung Bodenk.* **11A**, 229-64(1928).—For the study of the influence of the H-ion concn. on the adsorption of certain cations and of phosphates, soils of different replaceable base content were prepd. by treating an almost neutral soil with 0.1 *N*, 0.4 *N*, 0.2 *N* and 0.01 *N* HCl and the soils subsequently washed free of chlorides. From analyses of the exts. it was ascertained that only the 0.1 *N* HCl attacked perceptibly the zeolitic complex of the soil (manifested by the Al in soln.). The titrable acidity by the Daikuhara-Kappen method increased with the increased removal of bases from the soil; *i. e.*, after treatment with the different concns. of HCl. Adsorption of K from KCl and NH_4 from NH_4Cl decreased with an increase in the removal of cation from the zeolitic complex, *i. e.*, with increased H-ion concn. of soil; however, adsorption of Ca from $CaCl_2$ increased with an increase in H-ion concn. of the soil showing that the adsorption was probably an exchange reaction between the cation of the salt and the Ca of the soil (in case of Ca absorption between the Ca of the $CaCl_2$ and the Al of the zeolitic complex). The adsorption of P_2O_5 from $Ca(H_2PO_4)_2$ increased with the increase in H-ion concn. in consequence of the formation of difficultly sol. phosphates, *i. e.*, Al phosphates. However, the adsorption of P_2O_5 from $(NH_4)_2$-HPO_4 was greatest in the untreated (less acid) soil because of the formation of difficultly sol. phosphates, $Ca_3(PO_4)_2$. The increase in the removal of bases from the soil decreased the buffer capacity of the soil to acids. A study of permutite following the same line of thought gave results which substantiated the soil results. After treatment with acids for the removal of bases (cations) and a neutralization to restore the bases, the adsorption of bases by the soil does not reach the amts. in the untreated soil or permutite, showing that the treatment with acids has partly disintegrated and removed the zeolitic complex. Analyses of acid-treated permutites substantiated this finding. The different methods for the detn. of the replaceable bases were compared and the method of Gedroiz-Hissink was found to be the most reliable. A method for the estn. of the replaceable CaO in $CaCO_3$-free soil by shaking 100 g. of soil with 250 cc. of *N* KCl soln. for 1 hr. and filtering, detg. the CaO in 125 cc. of the filtrate and multiplying by the factor 2.5 gave relatively satisfactory results when compared to results obtained by the Hissink method. By treatment of 50 g. of soil with 250 cc. 0.1 *N* HCl, shaking for 1 hour, filtering after 24 hrs., titrating 125 cc. of the filtrate with 0.1 *N* NaOH with phenolphthalein as an indicator, the "neutralization power" of the soil was detd. By expressing this power in mg. equivs., the total replaceable base content is detd. for acid soils and soils contg. no $Ca_3(PO_4)_2$ and $CaCO_3$. By due calcn. of the bases combined with the phosphate and as $CaCO_3$, the method gives satisfactory results with soils contg. phosphates and carbonates. R. M. Barnette

The significance of soil respiration in the carbon dioxide feeding of plants. P. Hasse and Z. Kirchmeyer. *Z. Pflanzenernahr. Düngung Bodenk.* **10A**, 257-99(1928).—Contrary to the findings of Lundegårdh (*C. A.* **22**, 292), the authors could not ascertain a significant variation of the CO_2 content of the air in various heights in and above the plants, during the day or in the night. No significant influence of the CO_2 from the soil could be detected. $^4/_5$ of the CO_2 set free from a soil planted to lucerne can be attributed to the respiration of the roots. An improved app. for *measuring the CO_2* content of the air is described. R. M. Barnette

Does the supply of soluble plant nutrients change in unfertilized and fertilized soils during the period of vegetation? H. Neubauer, W. Bonewitz and A. Schottmueller. Landwirtschaftlichen Versuchsanstalt Dresden. *Z. Pflanzenernähr. Düngung Bodenk.* **12A**, 108-14(1928).—Soils unfertilized and fertilized with different chemicals and stable manure were subjected to a period of incubation at an av. warm temp. (in green-house) and at an av. cold temp. (in cellar). Samples were taken for the Neubauer method for testing the sol. K_2O and P_2O_5 after 57 days of incubation and at intervals after this time. There was no significant difference in the quantities of K_2O and P_2O_5 taken up by the seedling in the soils held at the different temps. at the initial sampling nor subsequent samplings. The utilization of the K_2O applied to the soils was very high in all cases. It was better in the light than in the heavy soil. Fertilization with superphosphate increased the utilization of the added K_2O. Thomas meal decreased the utilization of added K_2O as well as soil K_2O. The utilization of the K_2O in manure was very large, 92 to 99% of the quantity applied being recovered in the seedlings. Also a larger % of the P_2O_5 applied in manure was absorbed by the seedlings than from any other P_2O_5 fertilization. Added K_2O had little or no influence

on the utilization of P_2O_5 added as superphosphate or Thomas meal. The P_2O_5 of superphosphate was utilized to about the same degree in both the heavy and light soil; on the other hand the P_2O_5 of Thomas meal was utilized better in the light soil than in the heavy soil. Further expts. with KH_2PO_4, beer barm and manure on a heavy soil, a light soil and sand gave a utilization of all forms of P_2O_5 and K_2O in the descending order sand, light soil, heavy soil. The P_2O_5 and K_2O in beer barm are readily utilized.
R. M. BARNETTE

Soil reaction and its influence on the results of the Neubauer method. B. DIRKS. Universität Halle, S. *Z. Pflanzenernähr. Düngung Bodenk.* **12A,** 65–95(1928).—The satn. curve of KCl exts. of zeolite-contg. as well as zeolite-free sandy soils were detd. before and after boiling. Zeolite-free soils give curves which agree closely before and after boiling. Zeolite-contg. soils give curves which deviate widely before and after boiling up to a p_H value 8–8.3, after which the curves of the boiled and unboiled suspensions tended in the same direction and lay closer together. From this, the zeolite content of a soil can be estd. by the amt. of lime water necessary to bring a boiled sample of the soil suspended in a KCl soln. to a p_H value of 8–8.3, while the p_H values before the boiling give no sharp limits of the amt. of lime necessary. Raising the p_H value over 8.3 may be brought about by $CaCO_3$ and by alkali carbonates. Soils were adjusted to p_H values varying between 2.9 and 9 by treating with acid or lime as required. The Neubauer plant method was used to study the absorption of P_2O_5 and K_2O from the soil by the seedlings increased from the lower p_H values up to a p_H value of about 6; from p_H 6 to 8.3 there was no significant difference in the absorption; however, at a p_H value higher than 8.3 there was a decrease in the absorption of the K_2O and P_2O_5. The absorption curve of K_2O and P_2O_5 in relation to the p_H values showed a distinct max. between 6 and 8.3. Without considering the lower absorption of K_2O and P_2O_5 by the seedlings in the extremely acid soils, D. attributes the lower absorption in the alk. range (above 8.3) to the presence of carbonate in the soil soln. By drying and heating to 80–100°, the sol. carbonate decreased and a subsequent increase in K_2O and P_2O_5 absorption at p_H values higher than 8.3 occurred. This can best be detected by boiling a KCl ext. of the soil. The shrinkage of the colloidal material of the soil upon drying cannot be the cause of the increased soly. of K_2O and P_2O_5. R. M. BARNETTE

The influence of pulverizing and drying of soils on their productivity. A. ACHROMEIKO. Landw. Akademie, Moskau. *Z. Pflanzenernähr. Düngung Bodenk.* **11A,** 65–89(1928); cf. *C. A.* **22,** 2427.—The H_2O-sol. P_2O_5, org. and mineral matter, nitrates and H-ion concn. of differently pulverized and dried soils were detd. in a 3-min. extn. of 200 g. of soil with 400 cc. of distd. H_2O. Changes in the degree of dispersion were observed by using the Robinson method. Detns. were made on soil handled in the following ways: (1) natural moist soil, (2) natural soil dried in the sun, (3) natural soil dried at 100–110° in the thermostat. The changes in the sol. P_2O_5, sol. org. and mineral matter and H-ion concn. do not depend upon the non-capillary porosity of a soil; the degree of the dispersion of the pulverized soil was higher than that of the natural soil, which in turn was higher than that of the soil with the crumb structure. Drying the soils in the sun increased the water-sol. P_2O_5, org. and mineral matter content of soils; alternate wetting and drying increased these sol. constituents more than a single drying. The drying decreased the amts. of nitrate. Drying in the thermostat and sterilization with steam in the autoclave increased the soly. of these constituents more than did drying in the sun. The sol. P_2O_5 and org. and mineral materials diminished by keeping the previously dried soil in a moist condition. The amt. of nitrates increased with this treatment. The action of high temp. on the soil was to increase significantly its acidity. By maintaining soils dried in this manner in a moist condition, the H-ion concns. of water exts. and suspensions decreased, which decrease is dependent upon the activity of the soil microörganisms, as such a change did not occur under sterile condition or in the presence of antiseptic media. The increase in soil acidity caused by heating the soil to the higher temps. is correlated with increases in the amts. of sol. acid org. matter. Previously dried soils which were moistened and kept under sterile conditions showed no change in the sol. org. matter, but the soly. of the P_2O_5 decreased very markedly. Drying increased the degree of dispersion of the org. matter of the soil, but decreased the degree of dispersion of the mineral portion of the soil. Drying in thermostats was equally active in increasing the degree of dispersion of the org. part of the soil and decreasing the degree of dispersion of the mineral portion; however, the sun was more active in decreasing the degree of dispersion of the mineral portion than in increasing that of the org. portion. By wetting the dried soil it returned to the state of aggregation, which it showed before drying. R. M. BARNETTE

The significance of the absorptive power and the water-conducting ability of the

soil for plants. HANS GRADMANN. *Ber. deut. botan. Ges.* **46**, General Meeting Number, 68-73(1928).—Plants through their own absorptive power can overcome to some extent the absorptive power of the soil and the resistance to the movement of water through the soil. Different types of soil give up different amts. of water under conditions of increased suction. These factors should not be overlooked in ecology. L. P. M.

The determination of the organic, especially the humified, substance in soils. ULRICH SPRINGER. Geol. Landesuntersuchung am Oberbergam, München. *Z. Pflanzenernähr. Düngung Bodenk.* **11A**, 313-59(1928).—From a critical examn. of the different methods of detg. the org. matter of soil, S. maintains that the CrO_3 method as modified by him gives results which agree closely with the complete elementary oxidation of the org. matter by the combustion method. The method consists in the wet oxidation of the soil org. matter with 3.3 g. CrO_3, 10 cc. water and 50 cc. of H_2SO_4 to .1-20 g. of soil. The gases are passed over a tube contg. CuO and lead chromate to insure a complete oxidation; subsequently the gases are washed in concd. H_2SO_4 or passed over $CaCl_2$ for drying before absorption in KOH. The danger of the application of a factor for the conversion of CO_2 (or C) into org. matter is shown by the difference in the C content (cellulose 44.4% C, lignin 55.5% C, pectin about 40% C, humic acid 57.5-60% C, acidum hum. (Merck) 59.77% C, Kasseler brown 62.0% C) of the heterogeneous org. matter of the soil, and S. recommends, therefore, that the C content be always given in addition to the calcd. % of org. matter. For the estn. of the humified substance, the extn. with ammonia, pyridine, etc., gives very unsatisfactory results. Extn. with 5% NaOH and oxidation of the humified substance with $KMnO_4$ have given better results than other methods. The use of 5% soda soln. gives low results, but gives more satisfactory results than the NaOH extn. if colorimetric methods are used. The NaOH decomposes the humic acid and decreases the color intensity of the ext. Uncertainty of the colorimetric method due to its dependence on definite standard prepns. which might or might not be present in the ext. is emphasized. The method of Lapicque and Barbé and the H_2O_2 method do not estimate the humus content of the soil but do give valuable information relative to the easily oxidizable org. matter of the soil. The purification of the humified substance in the soil by the extn. of plant residues and intermediate decomposition products from the soil by AcBr and subsequent detn. of the humified substances in the residue (*i. e.*, by wet combustion method above) is thought to be the most satisfactory method. 45 references are cited. R. M. B.

The chemistry of the organic substances of the soil. A. SHMUK. *Abhandl. Kuban. Landw. Inst.* *Teil I, Lfg. 2*, **1923**, 1-91; *Biedermann's Zentr.* **56**, 289-91; *Chem. Zentr.* **1927**, II, 1389.—The paper contains first a survey of the org. substances existing in the ground and of their compn. In the 2nd part, S. goes into detail about the compn. of the humic acid. According to his investigations, it contains about 14% resinic acids and esters, and about 80% humic acid. The latter is of acid character and contains hydroxyl as well as carboxyl groups. Analysis as calcd. for the ash-free substance gave C 61.8, H 4.2 and N 3.2%. The ash is not bound organically. N is present in the form of the ordinary protein compds. The approx. formula is $(C_6H_4O_3)n$. G. SCHWOCH

Composition of natural organic materials and their decomposition in the soil. III. The influence of nature of plant upon the rapidity of its decomposition. SELMAN A. WAKSMAN AND FLORENCE G. TENNEY. New Jersey Agr. Expt. Sta. *Soil Science* **26**, 155-71(1928); cf. *C. A.* **22**, 1424.—A study was made of the influence of the compn. of plants on decompn. processes and their modification by addition of available nutrients to plant materials. Plants were selected which have a marked variation in compn. Materials used were rye straw harvested as hay, mature corn-stalks, mature oak leaves, stems and leaves of alfalfa tops, pine needles and moss. In most plants, especially when they are mature, there is a lack of balance between the available carbohydrates and the available N and minerals required by the microörganisms which bring about the decompn. of the plant. In those cases, the presence of additional inorg. nutrients greatly hastens the decompn. processes. A number of other factors, such as nature of microflora and microfauna active in the decompn., proper aeration and soil reaction, modify the rapidity and nature of decompn. of the plant material. These factors influence the rate of evolution of CO_2, the amt. of soil org. matter resistant to decompn. that is formed, and the rapidity of liberation of N and of mineral plant constituents. J. J. SKINNER

The coagulation of the soil. L. SMOLIK. *Vestnik Ceskoslov. Akad. Zemedelske* **1926**, 221; *Biedermann's Zentr.* **56**, 193-4; *Chem. Zentr.* **1927**, II, 1389.—The colloidal state of the soil depends on temp., content of electrolytes and tilling. In this study the variability of the total surface with different temps. was examd. The hygroscopicity was detd. according to Mitcherlich, the activity of the catalase according to Koenig.

By air-drying, the soil lost 11-15% of the active surface, and the activity of the catalase decreased. Continual frost had no noteworthy action. G. Schwoch

Determination of the quantity and "quality" of colloids in soils. G. W. Conrey. Ohio Agr. Expt. Sta. *J. Am. Soc. Agron.* **20**, 893-9(1928).—The importance of a detn. of a quantity of colloids in connection with mech. analysis is stressed and the possibility of its substitution for that of the clay-fraction detn. is suggested. In detg. the quantity of colloids the ratio methods are apparently the best available at present. The importance of the quality factor is stressed and further study is necessary to det. what detn. will serve best to characterize the quality of the colloid. E. F. Snyder

Colloidal behavior of soils and soil fertility. IV. Anion effect on the precipitation reactions and degree of dispersion of aluminum and iron hydroxides. J. S. Joffe and H. C. McLean. N. J. Agr. Expt. Sta. *Soil Science* **26**, 47-59(1928); cf. *C. A.* **20**, 639, 1295, 2039; **21**, 4002.—In the presence of the SO_4 anion all of the Al from a 0.0075 *M* soln. is transformed into the gel at p_H 4.7 to 4.8. No sol state of Al exists in the presence of SO_4. The complete pptn. of Fe of the same molar concn. in the presence of SO_4 anions takes place at the zone of p_H 3.2 to 3.8. There is a sol state of Fe under the influence of SO_4 which is transformed into the gel state upon removal of electrolytes by dialysis. In presence of the Cl ion complete Al pptn. from a 0.0075 *M* soln. takes place at p_H 5.4. Molecularly dispersed Al may persist almost to the point of complete pptn. Fe colloid gave similar results with the Cl ion. Molecularly dispersed Fe disappears as soon as the gel appears. Removal of electrolytes does not convert Fe sols into gels in the presence of Cl anions. NO_3 causes complete pptn. of Al at p_H 5.8 to 6.0, and of Fe at p_H 5.4. The NO_3 anion produces similar results to those obtained with Cl. In mixts. of anions the bivalent and tervalent anions control the states of aggregation of the Al and Fe colloids. Under normal soil conditions inorg. ions preclude the presence of Al and Fe in soln. Al may be in soln. from the dissocn. of Al silicate complexes in the soil. Iron is probably supplied to plants by the dissolving action of org. acids or other org. solvents. A. L. Mehring

Some physicochemical effects of organic soil colloids. Walter F. Loehwing. State Univ. of Ia. *Proc. Iowa Acad. Sci.* **34**, 149-52(1927).—An investigation undertaken to det. the reason for injurious effects of lime to grains grown on certain acid org. soils which occur in the Great Lake region. Analyses were made of the soils and crops to det. if a harmful phys. change occurred in the soils after liming or if lime was chemically injurious. Results seem to indicate that decreased potash assimilation is coupled with change from acidity to alky. in the soil or with release by replacement of some toxic substance. The latter is a possibility in this case as the soils contained moderate amts. of Fe, of which toxic quantities were liberated by liming. Clover maintained a const. supply of potash whether soils were limed or not. The best yields of clover were on limed soils. This shows a difference in nutrient requirement or absorptive capacity of roots. Because of the difficulty of securing dispersal of colloidal material, especially in org. soils, much work of the type here reported is open to question. Yet it appears that lime used to correct acidity and improve tilth on org. soils deficient in potash induces profound phys. and chem. changes in the soil which may be more objectional than the original acidity. With grains the injurious effect of lime is due to diminished K intake. Use of potash following lime injury to grains does not restore the yield on org. soils as it has been known to do on mineral soils The response of crops to lime differs according to their nutrient requirements and absorptive ability. W. G. Gaessler

The hydrogen ion concentration of some Porto Rican cane soils. E. J. Colon. *Facts About Sugar* **23**, 617-8(1928).—The p_H and CaO contents of various types of soil in one district of the Island were detd. From the results and from observations and reports on liming it is tentatively assumed that a soil p_H of 6.7 to 7 and a soil content of 0.3 to 0.4% available CaO by 1% citric acid is indicative of a good reaction, and around 0.03% CaO in the cane juice as a sufficiency of lime. J. F. Brewster

The work of Arrhenius on the Java cane soils. O. W. Willcox. *Facts About Sugar* **23**, 854-9(1928); cf. Arrhenius, *C. A.* **21**, 1830, 2350, 2351, 2569, 3411, 3414; **22**, 131, 132, 475, 1003, 2285, 2286; Bennett and Allison, *C. A.* **22**, 2804.—The work of A. for the Java Sugar Syndicate is reviewed and compared with the work of B. and A. on the soils of Cuba. Arrhenius' method of mapping soils on the basis of p_H, phosphates, and nitrification is contrasted with the American soil-type method. The article is illustrated with typical soil maps and with curves comparing percentage areas of sugar beet and cane lands classified according to soil p_H; cane growth plotted against the p_H of clay soil and of light soil; Ca phosphate plotted against p_H; and a relation between the nitrifying power of soil and the $(NH_4)_2SO_4$ requirement. M. J. P.

Results of soil analyses of a number of (Java) sugar mills. O. ARRHENIUS. *Arch. Suikerind.* **36**, III; *Mededeel. Proefsta. Java-Suikerind.* 807–20(1928); cf. *C. A.* **22**, 4195.—The soils of 13 mills were analyzed for p_H, P_2O_5, and nitrate production, and the soils of 5 of the mills also for Cl. The results are given in tables and maps. The principal advantage of soil analyses is that the field expts. will be more efficient and time will be saved, but cultural advice based on chem. analyses alone is not reliable. The variations in the soil are usually so great that samples must be taken short distances apart. The time for which the maps retain their usefulness is 8–10 yrs. in the case of p_H and P_2O_5, provided that the equil. is not disturbed by liming. The maps for nitrate production must be revised every 3 or 4 yrs., and the Cl detns. are of value only for the time at which the sample was taken. P. R. PEKELHARING

The estimation of iodine in soils. ROLAND V. NORRIS AND D. A. RAMA RAO. *J. Indian Inst. Sci.* **11A**, Pt. 7, 75–9(1928).—The method of Hercus, Benson and Carter (*J. Hyg.* **24**, 321(1924)) was tested on soils to which known amts. of I were added and was found unsatisfactory. Expts. with pure quartz sand to which I and Fe had been added indicate that the unsatisfactory results obtained were due to the Fe content of the soil. The method finally adopted is as follows: "The combustion of the air-dried soil is carried out in a Ni boat about 10″ long in a SiO_2 combustion tube in a stream of O. For soils rich in I 5 g. can be used, the quantity being increased if the figure is likely to be low. The combustion tube is heated to about 850° in a simple type of elec. furnace. One end of the tube is drawn out to a fine point which is bent over and passes directly into the absorption vessel contg. a small quantity of 10% NaOH. It is not necessary to use any cooling coil as suggested by McClendon. The combustion is continued for one hr., by which time all the I present in the sample will have been driven over into the alk. soln. The latter, together with the washings of the absorption vessel, is then transferred to a 100-cc. stoppered bottle and neutralized by the careful addition of H_2SO_4; 2 cc. of CCl_4 is added and the I liberated from the iodide by the addition of 3–5 drops of nitrosulfuric acid, prepd. by heating concd. HNO_3 with starch and absorbing the nitric oxide fumes in H_2SO_4. After vigorous shaking the CCl_4 contg. the I is sepd., washed twice with a very small quantity of H_2O and freed from acid by adding 2 cc. of $NaOOCCH_3$ solution. The I is then titrated with $N/1270$ $Na_2S_2O_3$. If necessary a second extn. with CCl_4 may be made. The $Na_2S_2O_3$ soln. is kept in the dark and standardized at frequent intervals." By this method 5 parts of I per 10 million can be detected and greater amounts estd. in a sample of 25 g. H. R. KRAYBILL

The cause of nitrification in Hungarian Szik (alkali) soils. F. ZUCKER. Tech Hochschule, Budapest. *Z. Pflanzenernähr. Düngung Bolenk.* **12A**, 102–7(1928).—Hungarian alkali soils were tested for their capacity to nitrify the NH_3 in an $(NH_4)_2SO_4$ soln. by inoculating a sterile $(NH_4)_2SO_4$ soln. with a small quantity of the soils. Liming increased the rate of nitrification of $(NH_4)_2SO_4$ in the limed alkali soils of Karczag in comparison with similar but unlimed soils of Nagyhortobágy, Ujszász, Tiszasas and Püspökladány in which nitrification of $(NH_4)_2SO_4$ occurred only in a few samples. The action of lime in increasing the nitrification in the Karczag soils extended to the lower depths. The increase in nitrification brought about by liming is attributable to greatly improved phys. properties, *i. e.*, increased aeration. The correlation of nitrification with weather conditions, aeration, etc , of these alkali soils is being studied. R. M.

Relation of climatic factors to the amount of nitrogen in soils. HANS JENNY. Univ. of Missouri. *J. Am. Soc. Agron.* **20**, 900–12(1928).—Analysis of soil samples coming from a wide climatic range shows that the total N content of the soil decreases in the United States from north to south in relation to temp. The change of the N content with temp. is a negative exponential function, provided the rainfall-evapn. ratios are const. For every 10° fall in mean annual temp., the av. N content of the soil increases 2 to 3 times. Practical aspects of the investigation, such as the maintenance and the increase of org. matter and N in the soil, are discussed. E. F. S.

The relation of exchangeable cations to the physical properties of soils. L. D. BAVER. Ohio Agr. Expt. Sta. *J. Am. Soc. Agron.* **20**, 921–41(1928).—The Ca ion produced no significant effect on the moisture equiv., hygroscopic coeff., and heat of wetting. It had a marked flocculating action on soils contg. a high % of clay. It had a tendency to increase the plasticity no. of the soil. No significant change in the moisture equiv. value was produced by the K ion. It decreased the hygroscopic coeff. detd. over 2% and 3% H_2SO_4 as well as the heat of wetting and had a deflocculating effect on the soil suspension. It lowered the plasticity no. of all the soils. The H ion showed no effect on the moisture equiv., hygroscopic coeff., and heat of wetting. It caused a decrease in the state of flocculation of the soil suspension. In soils highly satd. with bases it decreased the plasticity no. The plasticity no. was increased in soils

with a low degree of satn. The Mg ion showed no marked effect on the moisture equiv., hygroscopic coeff., or heat of wetting. It decreased, with one exception, the state of flocculation and had a tendency to increase the plasticity no. The Mn ion produced no significant effect on the moisture equiv., hygroscopic coeff., and heat of wetting. It produced a strong flocculating action below the neutral point. There was a slight tendency towards an increase in the plasticity no. Because of the highly puddled condition of the soil, the Na ion increased the moisture equiv. It decreased the hygroscopic coeff. as detd. over 30% H_2SO_4, as well as the heat of wetting. It caused a deflocculation of the soil suspensions and increased the plasticity no. of the soil by lowering the lower plastic limit. E. F. SNYDER

The application of the antimony electrode to the determination of the p_H values of soils. E. F. SNYDER. U. S. Dept. of Agr. *Soil Science* **26**, 107–11(1928).—In soil suspensions the Sb and H_2 electrodes showed very good agreement on soils ranging from p_H 3.6 to 9.2. Constant and reproducible potentials were generally obtained in about 1 min. The prepn. of Sb electrodes and the electrometric detn. are described. E. F. SNYDER

The significance of the hydrogen-ion concentration in soil nitrification studies. HARRY HUMFELD AND LEWIS W. ERDMAN. Ia. Agr. Expt. Sta., Ames. *Proc. Iowa Acad. Sci.* **34**, 63–6(1927).—Data are presented which show the relation of the reaction of the soil or its H-ion concn. to its nitrifying capacity. The initial reaction of the soil varied from as low a p_H as 5.16 to as high as 7.18. Indications are that nitrification goes on until a p_H of 4.4 to 4.8 is reached while from then on it proceeds slowly. Whenever the final p_H is below 4.2 the amt. of $(NH_4)_2SO_4$ nitrified is small. The data show that when $CaCO_3$ is added nitrification is increased considerably. The final reaction of the soil is somewhat more acid than the initial reaction, which seems to indicate that a somewhat larger amt. of $CaCO_3$ than the theoretical amt. is necessary completely to neutralize the acidity produced. On the whole, there is a close correlation between the soil reaction and the amt. of $(NH_4)_2SO_4$ nitrified. W. G. GAESSLER

The significance of hydrogen-ion concentration for the cycle of nitrogen transformed in the soil. CARSTEN OLSEN. *Compt. rend. trav. lab. Carlsberg* **17**, No. 8, 21 pp.(1928).—From these results it is evident that *ammonification* can proceed in soil whose p_H values lies between 3.7 and 9.0, and that this process proceeds most actively in soil whose p_H value lies between 7.0 and 8.5. Nitrification can proceed in soil whose p_H value lies between 3.7 and 8.8. When the soil is found to be rich in NH_3 the activity of the process increases from a value of 3.7 with the increasing p_H value of the soil to a p_H value of 8.3, at which the process has its optimum. From this point the activity of the process decreases very sharply with rising p_H values of the soil. In soil whose p_H value lies between 4.0 and 8.0 *nitrification* will under natural conditions generally be limited by ammonification, and the rate of the latter process will det. the rapidity of the process of nitrification. In strongly acid soil which is rendered alk. by the addn. of $CaCO_3$, there takes place very rapidly a powerful nitrification unless it is necessary to add inoculating soil from an alk. reacting soil. Providing the nitrifying bacteria working in the acid soil are special kinds which cannot work in alk. soil, the bacteria working in the alk. soil must either be found in slight quantities in the originally acid soil or appear spontaneously with dust. The nitrifying organisms are not killed when the soil in which they appear is air-dried at ordinary room temp. These organisms can be distributed as dust from one locality to another. E. F. SNYDER

The nitrogen-fixing microörganisms of an arid soil. E. G. CARTER AND J. D. GREAVES. Utah Agr. Expt. Sta. *Soil Science* **26**, 179–91(1928).—A study of the physiol. activities of the microörganisms of an arid soil from the Naphi Expt. Farm, Utah, indicates that 26 of the 27 studied are N-fixing organisms. Most of the cultures hydrolyze starch rapidly; 10 out of 27 reduced nitrates to nitrites with varying ability. J. J. SKINNER

The sulfur cycle in soil. AUGUST RIPPEL. Univ. Göttingen. *J. Landw.* **76**, 1–10(1928).—It must be again emphasized that the results are of a tentative nature, but they show clearly enough that it is absolutely necessary in the future to pay more attention to the different stages of the S cycle. That is also true for the fixation of S as organically bound S of humus substances, and further for the gradually, although as has been shown apparently slowly proceeding mineralization, since the largest part of the soil S occurs in the organically bound form. It is further true for the other behavior of sulfates in soil. In contrast to N they are worked up by the green plants only to a small part to organically bound S. Also the sulfates in the soil not worked up by the plants are assimilated by microörganisms in the presence of sufficient C compds., gradually fixed analogous to the organically bound N. It is especially important also,

over the pure culture of oats on the raw phosphate cultures. The mustard and oat combination showed an increase in the yield of the oats of 113% over the pure oat culture in the raw phosphate series. The yields of millet on raw phosphate were increased 103 and 856% by seeding with buckwheat and lupine, resp. Analyses of the solns. drawn from the cultures showed a higher H-ion concn., a lower Ca content and a higher P_2O_5 content in the cultures planted to buckwheat, mustard and lupine than in those from cultures planted to oats and millet alone. It is concluded that the difference in the utilization of raw phosphate by the different plants is due to the difference in the absorption of Ca and the difference in the action of the plants on the reaction of the soln. A difference in the absorption of P_2O_5 plays no significant part in this varied action of the several plants. R. M. BARNETTE

The relative solubility of phosphate and potash in German and tropical soils. H. VAGELER. Königsberg i. Pr. *Z. Pflanzenernähr. Düngung Bodenk.* **11A,** 89–93(1928).—For a comparison of the soly. of P_2O_5 and K_2O in German and tropical soils, 12 of each such soils were tested by detg. the soly. of the P_2O_5 and K_2O in HCl (concn. not given) and by the Neubauer plant method. Approx. 26.2% of the K_2O sol. in HCl was recovered by the Neubauer method for the German soils, while in the tropical soils 48.8% of the K_2O sol. in HCl was recovered by the plant method, despite the fact that the content in HCl-sol. K_2O was significantly higher in the German soils than in the tropical soils. In contrast to K_2O, the soly. of P_2O_5 in the tropical soils is proportionally less than in the German soils by the Neubauer tests (3.2% of the HCl-sol. P_2O_5 for tropical soils against 6.6% of the HCl-sol. P_2O_5 for German soils. At the same time the content in HCl-sol. P_2O_5 is significantly higher in tropical soils. R. M. BARNETTE

The unavailability of phosphorus in rock phosphate to some southern crops. R. P. BARTHOLOMEW. Arkansas Agr. Expt. Sta. *J. Am. Soc. Agron.* **20,** 913–20(1928). Cotton, cowpeas, sorghum, seredella, beggarweed, *Lespedeza*, bur clover, rice and velvet beans made very little growth when P was supplied as rock phosphate. Vetch made about $^1/_3$ and sweet clover about $^3/_4$ as much growth from rock phosphate as with superphosphate. There was no definite relation between the Ca-P ratio in the plants and their ability to feed upon rock phosphate. Other factors than the Ca content of the plants seem to play an important part in detg. the ability of plants to use rock phosphate as a source of P. E. F. SNYDER

The fertilizing value of the phosphates of Niezqiska on the Dnjester in southeastern Poland. KAZIMIERZ STRZEMIÉNSKI. *Kosmos. J. Soc. Polon. naturalistes "Kopernik"* **51,** I-IV A, 14 pp.(1926); *Chem. Zentr.* **1927,** II, 1748.—The suitability of phosphate meal from Niezqiska was proved by its soly. in 2% citric acid and by vegetation expts. with oats in the presence of $(NH_4)_2SO_4$ C. C. DAVIS

Phosphoric acid in soils and in cane juices. E. D COLON. *Facts About Sugar* **23,** 87–8(1928).—Expts. upon the relation of available P_2O_5 (by 1% citric acid) in the soil to the P_2O_5 content of cane juices are compared with similar expts. in Hawaii (*C. A.* **18,** 877). It is suggested that 0.03% P_2O_5 in ripe cane juice be adopted as indicative of soil sufficiency in this ingredient and the tentative figure of 0.015% P_2O_5 in the soil The variance of the latter figure with the Hawaiian 0.004% is large, but 0.015% P_2O_5 is on the safe side while further efforts are made to collect evidence which might draw the 2 standards nearer. J. F. BREWSTER

Studies with sulfur for improving permeability of alkali soils. JOSEPH D. HAYES. Oregon Agr. College. *Soil Science* **25,** 443–6(1928).—Alternate wetting and drying increased the permeability of a dispersed black alkali soil. S treatment increased the rate of percolation from alkali soil and decreased the total alky. S-treated soil remained more open and permeable in extended percolation trials than non-treated soil. S treatments of soil subjected to leaching cause Ca to become reactive and to disperse Na or the ultra-clay complex. J. J. SKINNER

Oxidation of sulfur in limed and unlimed soils. O. M. SHEDD. Kentucky Agr Expt. Sta. *Soil Science* **26,** 93–105(1928).—This investigation consists of a study of the oxidation of S both in the presence and absence of $CaCO_3$ when added to 31 surface soils from the principal soil areas of Kentucky. Every soil oxidized appreciable quantities of the added S, with or without $CaCO_3$, in 30 days and still larger quantities after 120 days, which was the duration of the expt. The quantity of S added was 250 p. p. m. of the air-dried soil and the amt. of the added S which was oxidized after 30 days in the unlimed soil varied from 8.8 to 36%, whereas in the limed soil it varied from 6 to 37.2%. After 120 days, the amt. varied from 20.8 to 61.6% in the unlimed soils and from 17.2 to 64% in the limed samples. The differences between the above max. and min. ranges in the limed and unlimed samples for the same period of time are not significant. Very little consistent relation was found between the H-ion concns. of the treated soils, either

in their initial or final p_H values, and their acidity or alky. by titration or the amts. of added S oxidized by them. The amts. of acid found in the samples by the titrations were usually not in proportion to the quantities of S oxidized by them. The soils treated with $CaCO_3$ were nearly all rendered neutral or nearly neutral. The averages show that the soil that had been kept moist for 120 days had a slightly lower p_H value than the original, and the soils, either limed or unlimed, to which S was added also had slightly lower av. p_H values than the corresponding samples without S. J. J. S.

A study of the effect of commercial fertilizers on the performance of apple trees. J. R. COOPER. Ark. Agr. Expt. Sta., *Bull.* **227,** 1–61 (1928).—An 8-yr. study at Fayetteville on Ben Davis variety is reported. A fertilizer formula consisting of 8% P_2O_5, 4% N and 4% K_2O was adopted as standard and the orchard was divided into plots in order to test the 3 elements in combination, in pairs and alone. P produced more fruit spurs and definitely increased both the setting and yield of fruit. P also made a very decided increase in the growth of the orchard cover crops; N caused good gains in terminal and trunk tree growth, no. of fruit spurs, set and total crop of apples. $NaNO_3$ was slightly more effective than $(NH_4)_2SO_4$ during the first 2 yrs. of the expt., but after the second yr. no differences were noted. No gains over check in either growth or yield resulted from the use of K compds. N delayed ripening and reduced the red color of the fruit, largely because the increased density of the foliage reduced the amt. of light reaching the fruit. Neither P nor K appreciably affected fruit color or maturity. The quality of apples was not affected by any element or combination of fertilizers. Ranked according to net gains 8 - 40 - gave the best results, followed by N alone. There was a definite positive correlation between tree vigor and crop yield. Non-pruned trees produced more fruit than those receiving any kind of pruning. The no. of fruit spurs formed per tree gives a good indication of what the crop yield will be. C. R. F.

The effect of sodium chloride and carbonate on the growth of asparagus. BURT L. HARTWELL, JOHN B. SMITH AND S. C. DAMON. Rhode Island Agr. Expt. Sta., *Bull.* **213,** 16 pp. (1928) -In plots expts. with asparagus Na salts were applied for several years, the amts. each year increasing until 2000 lbs. per acre was reached. KCl tended to decrease active soil acidity and NaCl increased it. The alkaline carbonates decreased acidity. Where heavy rainfall prevailed over a period of 2 months active acidity and active alumina were reduced. When Na was omitted the yield of asparagus decreased. In K-deficient plots NaCl and Na_2CO_3 increased the yields. J. J. SKINNER

The influence of stimulants on the sprouting of potatoes. WILHELM VON VELSEN. Univ. Göttingen. *J. Landw.* **76,** 41–62 (1928).—Chem. and phys. methods of stimulating the sprouting of 3 varieties of potatoes were tested. Although the phys. methods were ineffective a no. of chem. agents hastened the sprouting. Marked effects were obtained by treatment with HCN, thiourea, ethylene dichloride and K thiocyanate, or injection of diastase. The total wt. and no. of sprouts were increased by these reagents. On following the development in spring and summer, however, no differences could be observed between treated and untreated tubers E. F. SNYDER

A survey of some emulsion problems confronting the sprayer. R. M. WOODMAN. Cambridge Univ. Hort. Research Station. *J. Pomology Hort. Sci.* **6,** 313–8 (1928); cf. *C. A.* **21,** 1325.—Two types of emulsions are possible when coal-tar or petroleum fractions are shaken with H_2O. They are oil-in-water and water-in-oil. The relative proportions of the ingredients and the manner of prepn. det. the kind of emulsion. Only the oil-in-water type of emulsion is of any value as a toxic spray. Methods for overcoming difficulties arising from the use of hard H_2O in making emulsions are given. Fourteen references are appended. A. L. MEHRING

Chemical testing of nicotine dusts. W. R. HARLAN AND R. M. HIXON. Iowa State College. *Iowa State Coll. J. Sci.* **2,** 313–6 (1928); cf. *C. A.* **18,** 1028, 1875; **19,** 1174; **21,** 2524; **22,** 2808.—When nicotine is absorbed by bentonite considerable heat is evolved. When the nicotined dust is extd. with ether for 12 hrs., a 3% dust retains 88% of the nicotine, a 6% dust 45% and a 14% dust retains 20% of the nicotine. In g. of nicotine per g. of bentonite these are 0.0264, 0.0276 and 0.0280, resp. Water removes very little nicotine from the original dusts and they have but little odor of nicotine. The addn. of $Ca(OH)_2$ increases the proportion of nicotine extractable by ether. The retained nicotine may be quantitatively recovered from the bentonite by steam distn. When nicotine vapors pass through a train which permits any contact with rubber, nicotine content and toxicity to rice weevil decrease. When the train is all glass, neither analysis nor the no. of weevils killed decrease in succeeding containers. Searches for reaction products of nicotine especially oxynicotine were fruitless. Conclusion: Losses of nicotine on adsorbents and in trains should be ascribed to *adsorption of nicotine* not to chem. change. F. E. BROWN

An investigation of spray coverages and arsenical residue in relation to the control of the codling moth. R. H. Smith. Univ. of Calif. Citrus Expt. Station, Riverside, Calif. *J. Econ. Entomol.* **21**, 571–88(1928).—See *C. A.* **21**, 978. C. H. R.

Progress report on the use of petroleum oil as an insecticidal spray. E. R. deOng. *J. Econ. Entomol.* **21**, 525–9(1928); cf. *C. A.* **22**, 3482.—The use of petroleum oils with high unsulfonated residues as insecticides on citrus trees and deciduous trees in foliage has recently shown a marked increase. The oil concn. for citrus trees is generally 2%, for deciduous trees 1–1.5%. Dormant spraying of deciduous trees with com. oil emulsions has also been widely practiced with little tree injury due to favorable weather and the more highly refined oil used (unsulfonated residue ranging as high as 70%). The use of petroleum oils on citrus trees is still accompanied by functional disturbances (non-coloring of fruit, premature fall of fruit, dearth of bloom, early decay of fruit in storage) due in part, at least, to oils of too low volatility. This may be partly overcome by the use of oils of great volatility. Besides the sulfonation test (cf. Gray and deOng, *C. A.* **20**, 963), the oxidation rate of oils promises to be valuable in detg. safety to the plant (cf. Sligh, *C. A.* **19**, 1491). The incorporation of nicotine and other active insect poisons directly into the oil before emulsifying it offers possibilities. Cf. deOng (*C. A.* **22**, 4197). C. H. Richardson

The use of oil sprays on citrus during 1926. R. S. Woglum. Calif. Fruit Growers Exchange, Los Angeles Calif. *J. Econ. Entomol.* 21, 530–1(1928); cf. *C. A.* **21**, 793.—Highly refined (white) petroleum oils of the lubricating type were quite extensively used in sprays for citrus insects in Calif. in 1926. The oils were generally high in unsulfonated residue but differed somewhat in viscosity and sp. gr. A marked difference in the rapidity with which the oil film disappears from the tree was noted among the various oils and was reflected in the effects upon scale insects and the trees. Such injuries as retarded coloration of fruit, crop reduction and impared quality were sometimes noted. Injury has been reduced by making fewer applications, avoiding cold-weather spraying, and by delaying the picking of fruit. A combination of oil spraying and HCN fumigation is the most successful way of controlling resistant scale. The control of the red spider by means of oil sprays varied with the type of oil used and the time of application of the spray. C. H. Richardson

A new method of using fish oil as an adhesive (in lead arsenate sprays for the gypsy moth). B. A. Porter and R. F. Sazama. *J. Econ. Entomol.* **21**, 633–4(1928).—Eight lbs. $PbHAsO_4$, and 14 lbs. water are worked into a paste, then 2 lbs. fish oil are added and the mixt. is pumped 2–3 times. It adheres very well on plant foliage. Similar mixts. may also be made with $BaSiF_6$, K_2SiF_6 and cryolite but are improved by the addn. of a casein and lime prepn. C. H. Richardson

A comparison between complete and incomplete digestion of sprayed apple foliage in determining arsenic by the Gutzeit method. J. M. Ginsburg. N. J. Agric. Expt. Station. *J. Econ. Entomol.* 21, 588–92(1928).—For complete digestion, the sprayed foliage was finely ground and digested with HNO_3 and H_2SO_4 until all org. matter had passed into soln. Incomplete digestion was accomplished by boiling the plant material with 10% HNO_3 or 20% HCl for 30 min., then filtering and washing. The amts. of As_2O_3 recovered were practically the same in both cases but the second method requires less time and is more convenient. C. H. Richardson

The germination and early growth of wheat treated with copper carbonate and tillantin R. K. Simpson and D. W. Davies. Univ. Coll., Wales. *Ann. Appl. Biol.* **15**, 408–22(1928).—The stimulating effects of $CuCO_3$ and of the proprietary substances, "uspulum" and "tillantin," upon wheat are in most cases due to the fungicidal properties of the prepns. These chemicals cannot be classed as plant stimulants. C. H. R.

English grown pyrethrum as an insecticide. I. J. C. F. Fryer, F. Tattersfield and C. T. Gimingham. Ministry of Agr. and Rothamsted Expt. Sta., Eng. *Ann. Appl. Biol.* **15**, 423–45(1928).—Pyrethrum flowers (*Chrysanthemum cinerariaefolium*) grown in six localities in England had equal toxicity to aphids (*Aphids rumicis*) and certain caterpillars and did not differ from samples grown in continental Europe. Extracts of equal weights of pyrethrum flowers tested at different stages of development differed very little. Artificial drying of the flowers did not affect their toxic properties. Wt. for wt., the flowers were about ten times as toxic as the stalks. Prolonged exposure of pyrethrum to dampness caused some loss in toxicity but if stored in a reasonable manner, its toxicity was retained for a long period. C. H. Richardson

Investigations in combating scab in North Bohemia. Frieder. Zimmermann. Sta. f. Pflanzenschutz, Tetschen, Liebwerd. *Z. Pflanzenkrankh. Pflanzenschutz* **38**, 208–15(1928).—"Nosprasen," a prepn. contg. Cu and As, was found effective against apple scab (*Fusicladium dendriticum*) when applied as a spray in 1.5% soln. after blossom-

ing and again one month later. This treatment had no effect on the caterpillar of *Laspeyresia pomonella*. LAWRENCE P. MILLER

Leaf scorch on fruit trees. T. WALLACE. Univ. of Bristol Hort. Res. Station. *J. Pomology Hort. Sci.* **6**, 243–81(1928).—Gooseberry bushes planted in sand were given a nutrient soln. lacking K_2O. The foliage of some of the bushes was sprayed with a 1% soln. of K_2SO_4 and that of the others with H_2O. The spray was prevented from reaching the roots. Treatment of the foliage with K_2SO_4 soln. effectively prevented leaf scorch, which was very bad on the other plants. Absence of the SO_4 radical had no effect. By continued water logging of the soil marginal leaf scorch can be produced in the presence of a complete nutrient in the soil soln. These expts. were repeated a second year with like results. With different varieties of apple trees in absence of K_2O leaf scorch appeared at different times but in each case the foliage had attained the same stage of maturity when it did appear. Analyses and descriptions of soils from a considerable number of leaf scorch centers are given. Either an excess or deficiency of soil H_2O seems to favor development of leaf scorch. In only 8 out of 46 areas was the available K_2O in the surface soil above 0.015%. In 5 cases from non-scorch areas the available K_2O was below 0.01%, but in every such case the mechanical analysis showed the soil texture and soil H_2O conditions to be much superior to that of scorch areas. Only 3 leaf-scorch soils contained below 0.01% available P_2O_5. Most of them were higher in P_2O_5 than ordinary soils. Both acid soils and these contg. as much as 31% $CaCO_3$ were obtained from scorch areas. Leaf scorch has often developed in orchards where nitrogenous and phosphatic fertilizers have been regularly applied but in none of these places have K_2O fertilizers been regularly used. A. L. MEHRING

The application of physiological methods to weed control. P. B. KENNEDY AND A. S. CRAFTS. Univ. of California. *Plant Physiology* **2**, 503–6(1927); cf. *C. A.* **13**, 1614; **14**, 86.—Field expts. on the spray control of morning glory (*Convolvulus arvensis*) with arsenicals of both acid and alk. reaction lead to the belief that the effectiveness is apparently dependent upon: (1) atm. and soil conditions which produce a water deficit resulting in a sub-atm. pressure within the xylem system, (2) a period of exposure to the spray of sufficient duration to provide for penetration of the toxic soln. Exposure may be extended by repeated spraying. Penetration is influenced by (1) insect injuries to the cuticle, (2) temp., (3) death of the cells, which renders the tissues readily permeable. There are 2 distinct functions to be performed by the spray soln.: (1) To make the tissues from the epidermis to xylem permeable. This is accomplished by acids, bases and hydrocarbons in the commercial sprays in use as weed killers. (2) To kill the tissue in the root after the soln. has been translocated into them. Arsenic is the most effective for this purpose. The problem remains to find agents more effective in fulfilling these requirements and to apply them under more ideal conditions than hitherto. WALTER THOMAS

Variations in the Mn content of certain vegetables (PETERSON, LINDOW) 11D. The selective absorption of inorganic elements by various crop plants (NEWTON) 11D. ENGLISH, L. L.: **Some Properties of Oil Emulsions Influencing Insecticidal Efficiency.** Urbana, Ill.: Ill. Dept. of Registration and Education.

GAZA, WILHELM VON: **Die Kalkverarmung unserer leichten Böden.** Berlin: Kalkverlag. 23 pp. M. 0.65.

Fertilizer. EMIL BAUER and FIRMA EISLER AND SZOLD. Austrian 108,903, Oct. 15, 1927. Molasses residues at a concn. not exceeding 35° Bé. are mixed with chalk at a temp. not exceeding 60°. The mixt. is dried and ground.

Fertilizers. E. W. M. HAMMEL. Brit. 284,741, Sept. 27, 1926. Bone meal or other suitable material contg. or yielding albuminoids or peptones is treated with an

inorg. acid such as HCl (but not using H_2SO_4) and a K-bearing fertilizer material is added during the treatment. The product is concd., free acid is neutralized with NH_3, and the material is then dried in a vacuum and may be powdered and mixed with peat meal.

Fertilizers. CHEMICAL PRODUCTS COMPANY. Fr. 635,919, June 13, 1927. Natural phosphate is treated with $(NH_4)HSO_4$ to produce $(NH_4)_3PO_4$. The $CaSO_4$ formed is treated with $(NH_4)_2CO_3$ to form $CaCO_3$ and $(NH_4)_2SO_4$, the latter being converted in $(NH_4)HSO_4$ for re-use.

Ammonium phosphate. G. H. BUCHANAN (to American Cyanamid Co.). Brit. 284,322, Jan. 28, 1927. Solid mono-ammonium phosphate is treated with gaseous NH_3 to transform it wholly or partly into di-ammonium phosphate and obtain a *fertilizer* richer in N. An app. is described in which NH_3 may be supplied under pressure (suitably up to 60 lb. per sq. in.) and in which the material may subsequently be subjected to a vacuum to remove both free NH_3 and that combined as tri-ammonium phosphate.

Neutral phosphate. GEORGES TRUFFAUT. Fr. 635,523, June 3, 1927. Natural phosphate is treated with H_3PO_4 in the presence of SiO_2 or other substances forming stable compds. with F, so as to obtain a neutral phosphate, partially defluorinated, assimilable by plants because of the dissocn. of fluophosphates and fluorides. The amt. of H_3PO_4 used should be such as to give a mixt. of 80% bicalcium phosphate and 20% monocalcium phosphate.

Treating growing tobacco or other plants. WM. EGGERT, JR. U. S. 1,686,964, Oct. 9. In order to improve the quality of tobacco, the roots are supplied, at blossoming time, with a fermented soln. of tobacco leaves and petals, contg. a sweetening agent such as molasses, honey or sugar together with gum benzoin. A similar treatment may be applied to other plants such as cotton or cauliflower (which may be treated with sassafras and asparagus material, resp.).

Treating plants with insecticides, fungicides, etc. J. C. SAVAGE. Brit. 285,515, Aug. 10, 1926. The exhaust of an internal-combustion engine (which may be that of an airplane or land motor vehicle) is used to distribute toxic substances such as As_2O_3, Cu carbonate or Cu hydrate which may be suspended in a cloud-forming oleaginous vehicle such as cottonseed oil or mineral oil.

Insecticide. N. G. AND N. N. GRUZOV. Russ. 4555. Sept. 15, 1924. 1- or 2-Naphthylamine or both are dissolved in kerosene.

Fungicide. I. G. FARBENIND. A.-G. Fr. 635,436, June 2, 1927. Seeds are treated with a mixt. contg., *e. g.*, 15 parts anhyd. $CuSO_4$, 21 parts Rochelle salt, 9 parts NaOH and 5 parts NaCl. Cf. *C. A.* **22**, 2435.

Dry fungicide. EMIL MOLZ (to Chemische Fabrik Ludwig Meyer). U. S. 1,685,-715, Sept. 25. A mixt. of $HgCl_2$ 15, an alk. iodide such as KI 3.5 and talc 81.5% is adapted for formation of Hg iodide in moist soil.

Destroying cacti with organic arsenic compounds. HUGO STOLTZENBERG. U. S. 1,686,582, Oct. 9. Compds. such as diphenyl arsine oxide dissolved with H_2SO_4 are sprayed on or injected into catic.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

History of alcohol and distillery. RENÉ PIQUE. *Chimie et industrie* Special No., 785–803(April, 1928). A. PAPINEAU-COUTURE

Studies of hydrogen-ion concentration and its significance in distilleries. W. DIEMAIR AND K. SICHERT. Inst. landwirtschaftliche Techn., Weihenstephan. *Biochem. Z.* **198**, 1–18(1928).—The changes in H-ion concn. and in titrational acidity were detd. in raw and steamed potatoes undergoing fermentation. S. MORGULIS

Fermentation by dried yeast preparations. II. ARTHUR HARDEN AND MARJORIE GIFFEN MACFARLENE. Lister Institute, London. *Biochem. J.* **22**, 786–9(1928); cf. *C. A.* **19**, 3283.—Various inorg. and org. salts (Na arsenate excepted) added to zymin placed in a large vol. of sugar soln. reduce the period of induction before the onset of rapid fermentation. BENJAMIN HARROW

The preparation of glycerol by the fermentation process. IRENA LIPSKA. *Roczniki Farmacji* **5**, 80–4; *Chem. Zentr.* **1927**, II, 947.—A biological investigation of the dependence of the yield of glycerol on the type, age and method of culture of the *yeast*. The yield varies with the concn. of Na_2SO_3 and *sugar*. J. S. REICHERT

Explosion risk in the industrial preparation of absolute alcohol from sulfite spirit. ERNST SCHLUMBERGER. Lichterfelde. *Papierfabr.* **25,** Tech.-Wiss. Teil 704(1927).—EtOH-air mixts. are to be avoided in the prepn. of abs. EtOH from sulfite spirit. The use of an inert gas is recommended. The explosive range of EtOH-air mixts. is about 4 times as great as with C_6H_6. J. L. PARSONS

The production of power alcohol from waste vegetable materials, such as grass, straw and husks. A. C. THAYSEN AND L. D. GALLOWAY. Royal Naval Cordite Factory, Dorset, Eng. *Ann. Appl. Biol.* **15,** 392–407(1928).—The hemicelluloses of various waste vegetable materials can be hydrolyzed by acids to yield exts. fermentable by alcohol-forming bacteria. The conditions under which *B. acetoethylicus* can be utilized to ferment the exts. obtained by hydrolsis of various plant materials have been studied. The conditions necessary for the tech. use of this fermentation have been ascertained. The prepn. and sterilization of the mashes may be carried out at temps. not exceeding 100°. The yield of alc.-acetone mixture in gals. per ton of raw material was as follows: *Hyparrhenia glauca* 18, corncobs 22.5, Esun grass 17, *Phormium tenax* 10, rice husks 14, rice straw 19, wheat straw 16, *Andropogon gayanus* 20, *Andropogon tectorum* 22, sorghum stems 17, papyrus (air dry) 16.5, sisal-hemp residue 4.8, sugar-beet residues 24.7. C. H. RICHARDSON

The industrial manufacture of absolute alcohol. JEAN BARBAUDY. *Ann. office nat. comb. liquides* **3,** 191–218(1928).—The miscibilities of C_6H_6, C_6H_{14} and C_7H_{16}, resp., with EtOH-H_2O mixts. are discussed in this review of 40 references. Distn. of aq. EtOH over CaO at 5 atms. pressure effects dehydration in about $^1/_5$ of the time required under atm pressure with only about 2% loss. The addn. of $C_3H_5(OH)_3$ to EtOH-H_2O mixts. produces a ternary system from which EtOH contg. approx. 0.7% by wt. of H_2O is obtained by distn. Anhyd. alc. can also be obtained by distg. aq. alc. under a pressure of 7 cm. of Hg. The distn. of EtOH-H_2O mixts. in the presence of C_6H_6 under 10 atms. pressure is the most efficient method for producing anhyd. EtOH. In practice petroleum distillate, d^{15}_{15} 0.72–0.73, may be used instead of the more expensive C_6H_6. R. E. SCHAAD

Sugar cane bagasse as a source of alcohol. WM. L. OWEN AND WM. P. DENSON. *Planter Sugar Mfr.* **80,** 61–4, 83–5, 102–5(1928).—Preliminary expts. with baled bagasse demonstrated (1) that the fermentable sugars in bagasse can be efficiently converted into alc. by fermentation. (2) That the rate of fermentation of solns. was accelerated by the addition of bagasse even where the alc. yields from the sugars present were not increased. More elaborate expts. on a lab. scale indicate that higher yields of alc. from fermenting molasses may be expected and that by addition of bagasse to worts of high density (33 Brix) a 25% greater alc. yield is obtainable in $^1/_3$ shorter time. In order to preserve the exhausted bagasse chips for the manuf. of *fiber board,* these may be subjected to acetic fermentation by substitution for beech shavings in vinegar generators. A line of procedure for the utilization of bagasse in the fermentation industry is suggested and its value in the distillery calcd. as well as the possibility of the absorption of Louisiana bagasse by local distilleries and the value of spent bagasse for the manuf. of fiber board. J. F. BREWSTER

The wood-alcohol problem. I. The saccharification of cellulose. P. LEONE AND A. NOERA. R. Scuola d'Ingegneria di Palermo. *Ann. chim. applicata* **18,** 205–39 (1928).—A crit. survey of the literature on the conversion of cellulose to sugar and thence to alc. (many references to which are given) leads to the conclusion that only by simplification of the technic and the more economical use of a cheap com. agent, such as HCl at greater diln. than recommended by Willstätter, can any process become a success industrially. This unsatisfactory state induced L. and N. to carry out expts. to det. (1) the proportion of glucose destroyed by HCl of different concns. in different times; (2) the proportion of glucose which under standardized conditions is condensed to polysaccharides (which are readily hydrolyzed by heat after diln.) by different concns. of acid and in different times; (3) the influence of the concn. of glucose on the saccharification of the cellulose; (4) the saccharifying action of HCl of different concns. on a systematic series of samples, so that the influence of the temp., time, concn. of acid and proportion of acid on the cellulose could be ascertained; (5) the saccharifying capacity of HCl of different concns. in the presence of various concns. of $ZnCl_2$ and (6) the max. obtainable concn. of glucose by the use of HCl of different concns. in the presence and in the absence of $ZnCl_2$. All expts. were on a lab. scale, with pure reagents and standard methods of analysis. The proportion of glucose destroyed increased rapidly with increase in the concn. of HCl, *e. g.,* 15% of the glucose in a 4% soln. being destroyed in 24 hrs. by 40% HCl and only 0.75% of the glucose by 35.6% HCl. Conversely the condensation products decreased with increase in the concn. of HCl. The

proportion of glucose destroyed diminished with increase in its concn. until it reached an almost const. value. For a given concn. of glucose, the condensation products diminished with increase in the concn. of HCl and increased with increase in the concn. of glucose. There was no appreciable destruction or condensation of glucose after 2 days of contact with HCl. Glucose retarded the saccharification of cellulose and in high enough concns. inhibited the reaction completely. The proportion of cellulose which was saccharified by HCl increased very rapidly with increase in concn. of the HCl. Thus under 1 set of conditions 16% HCl did not attack cellulose, 20% HCl saccharified only 5%, 37% HCl saccharified 31% and 40% HCl saccharified 93%. With a high concn. of HCl, an increase of temp. above 30° caused the destruction of the sugar formed, whereas with HCl in lower concn. a small increase of temp. favored a high yield of sugar. Since HCl not only forms sugar but also destroys the products of hydrolysis, the time of contact is an important factor, and it was found that in general the max. yield of glucose was obtained after 48 hrs. of contact, though with acid of only 35% or less a longer period of contact was necessary. The yield of glucose varied with changes in the cellulose-acid ratio, which conforms to the hypothesis of an equil. in the reaction. The yield diminished with increase in the concn. of cellulose. Several reasons are given to show that hydrolysis is not confined to dissolved cellulose, but that the HCl attacks both dissolved and undissolved cellulose, perhaps depolymerization first taking place, followed by saccharification. $ZnCl_2$ increased the ability of HCl to form glucose from cellulose. Though 16% HCl was inactive in contact with cellulose, considerable of the latter was hydrolyzed when $ZnCl_2$ was added, and with the aid of $ZnCl_2$ 35% HCl gave a higher yield of glucose than 40% HCl without $ZnCl_2$, most likely because the destructive action was diminished. With HCl above 35% and below 30% concn. there was a limit to the $ZnCl_2$ above which further addn. diminished the yield of glucose, probably because of destruction of the glucose, or of the formation of cellulose-$ZnCl_2$ complexes. Further expts. in this connection showed that $ZnCl_2$ did not aid the destruction of glucose by 37% HCl but greatly aided it by 40% HCl. Glucose retarded the saccharification of cellulose by HCl and $ZnCl_2$ and if in high enough concn. inhibited it completely. With the addn. of $ZnCl_2$, the time to reach the max. concn. of glucose under normal conditions was in all cases 2 days, and temps. of 10–30° gave the best yields. With increase in the cellulose-acid ratio, the yield of glucose diminished in the same way and to the same extent as in the absence of $ZnCl_2$. Expts. to det. the highest concn. of glucose with different concns. of HCl and of $ZnCl_2$ showed that with 36–37% HCl the highest concn. of glucose obtainable was 13.66%, with the use of about 7 times as much HCl as glucose obtained. With the addn. of $ZnCl_2$, the concn. of glucose was much higher and the consumption of HCl was less. The optimum concn. of $ZnCl_2$ was around 20% but it was of advantage even in lower concns. Concns. of 25–30% glucose can be readily obtained with a consumption of HCl about 4 times the sugar obtained. With 37% HCl and 20% $ZnCl_2$ the concn. of the glucose was 34%, with a consumption of acid only 3 times the glucose. Further expts. on the recovery of the HCl and $ZnCl_2$ are to be described. C. C. Davis

Butanol fermentation process. C. L. Gabriel. *Ind. Eng. Chem.* **20**, 1063–7 (1928).—The industrial development of the production of butanol and acetone began in an effort to produce synthetic rubber from isoprene, dimethylbutadiene and butadiene. In 1911 Fernbach isolated a culture "FB" which fermented potatoes. Weizmann later isolated a culture "BY" which possessed the proper fermentative qualities, and the war caused the British government to aid in the development of a process for producing acetone. The Commercial Solvents Corp. took over the Allied War Board plants at Terre Haute in 1919. Butanol, formerly a by-product, and its derivs. served as a substitute for fusel oil and amyl acetate. Thereafter acetone was a by-product. The original Terre Haute plant had 40 fermenters. In 1927 148 50,000-gal. fermenters were in operation at Peoria and Terre Haute. Over 30,000 bu. of corn are used per day and 600 tons of coal. Each fermentation gives off 150,000 cu. ft. of gas consisting of approx. $^1/_2$ H_2 and $^1/_2$ CO_2 by vol. A 12-ton synthetic-NH_3 plant was developed to utilize the H_2. Later a synthetic methanol using the scrubbed fermenter gas from which part of the CO_2 is removed, compressed to about 4500 lb. and run over catalysts, was developed from the NH_3 plant. Three vols. H_2 combine with 1 vol. $CO_2 \longrightarrow CH_3OH + H_2O$. A large Development Division is located at Terre Haute. C. N. Frey

Carbon tetrachloride as a denaturing agent. W. Meyer. *Chem.-Ztg.* **52**, 712 (1928); cf. *C. A.* **21**, 981.—According to the regulations of the German Government, alc. is often denatured with 1.5 vol. % CCl_4. This practice proved to be harmful for the manuf. of certain drugs that require the use of alc., especially in the case of ferrum sulfuricum, oleum hyoscyami, resina jalapae and unguentum glycerini. They all are

of inferior quality, if CCl_4-contg. alc. is used in the mfg. process. Also the equipment is affected by CCl_4. M. recommends the denaturation with 1 l. petroleum benzene (d. 0.650–0.720 and b. 40–110°) for each 100 l. of alc. G. SCHWOCH

The quality of foreign fortified wines. M. RÜDIGER AND W. DIEMAIR. Hochschule Weihenstephan. *Z. Untersuch. Lebensm.* **55**, 144–8(1928).—Analytical data on 23 samples of French, Greek, Spanish, etc., fortified wines. WILLIAM J. HUSA

The clarification of wines. M. RÜDIGER AND E. MAYR. *Z. angew. Chem.* **41**, 809–12(1928).—Clarification of wines by phys. and chem. means is still a problem requiring investigation. Various methods for clarification are discussed. C. N. F.

The deacidification of wines and fruit wines. EDUARD JACOBSON. *Getränke-Ind.* **1926**, 49–50; *Chem. Zentr.* **1927**, II, 2124.—A discussion of the *elimination of acids by* $CaCO_3$, which, however, on account of the neutral decompn. of acids is never carried out with young wines and must. The addn. of $CaCO_3$ should not exceed the corresponding quantity of tartaric acid in the wine because otherwise sol. Ca salts remain behind, the harmlessness of which is not definitely established. C. C. DAVIS

How can the observed mistakes in the grape and fruit wine technic be avoided, what influence have they on the quality of the liquors, and how must the sample be taken for proper judging? TH. RÖTTGEN. *Süddeut. Apoth.-Ztg.* **67**, 481–3; *Chem. Zentr.* **1927**, II, 1409.—The changes due to yeast mold, whose action can with certainty be suppressed with CO_2 and SO_2, consist originally of a slight and later of an appreciable lessening of the alc., acid and ext. content. The sample should be taken at 12°. At a higher temp. the alc. disturbs the Burkett action. J. S. REICHERT

Chemical analysis of a Greek wine. GIOVANNI ISSOGLIO. *Giorn. farm. chim.* **77**, 3–7(1928).—A high-grade de luxe wine of Calandri (Athens) of 1924 vintage had a topaz-brown color, agreeable aroma, sweet taste, sp. gr. 1.0782 and contained 14.57% alc. (by vol.), 22.08% sugars, 3.68% solids besides sugars, 0.33% ash, 0.532% total acidity as tartaric acid 0.152% volatile acids as AcOH and 0.92% glycerol. The c_H was 0.28 millimol., alky. of the ash 28.4. The proportions of the org. acids are given. MARY JACOBSEN

Determination of glycerol in wines and liqueur wines. L. FERRÉ AND J. BOURGES. Station Oenologique de Bourgogne. *Chimie et industrie* Special No., 775–7(April, 1928).—A study of Pozzi-Escot's method (*C. A.* **8**, 776), which consists essentially in defecating the wine, distg. the glycerol at 100° with steam and in vacuum, and detg. oxidimetrically with $K_2Cr_2O_7$ in the distillate. F. and B. found that it is necessary to remove practically all the solids (particularly the sugars) before distg., which is best done by defecating with $Ba(OH)_2$ (technic described). A specially devized *vacuum distn. app.* is described, made entirely of metal (except the distn. flask, which is of glass) to eliminate rubber connections and stoppers. Oxidation of the glycerol is carried out by boiling the distillate 2 hrs. under a reflux condenser with H_2SO_4 and a measured excess $K_2Cr_2O_7$, adding excess of standard Fe^{++} NH_4 sulfate, and titrating with $KMnO_4$. The method is relatively simple and can be applied to all wines, irrespective of their compn., and particularly of their sugar content. A. PAPINEAU-COUTURE

Determination of manganese in the wines of Peloro (Sicily). GRAZIA SOLARINO. *Boll. chim. farm.* **67**, 481–3(1928).—The soln. of the ash of 100 cc. wine in concd. HNO_3 was boiled with 0.5 g. PbO_2 and allowed to stand. As soon as the supernatant soln. acquired a red-violet tint it was titrated with 0.01 *N* $C_2H_2O_4$. The Mn content was 0.0012–0.0024 g./l. Tabulated results of 20 samples are given. MARY JACOBSEN

A new apparatus for determining the color of wort and of beer and for determining the p_H value of physiological liquids. A. JODLBAUER. *Allgem. Z. Bierbrauerei Malzfabr.* **55**, 211–3; *Chem. Zentr.* **1927**, II, 1627.—The app. which is described and illustrated is constructed according to the Walpole principle by F. Hellige & Co. (Freiburg, Breisgau). Expts. with the app. show that it gives very good results when applied to problems in the brewery lab. C. C. DAVIS

Norwegian aquavit. (MISS) J. MOROY. Lab. Centrale du Ministére de l'Agr. *Ann. fals.* **21**, 344–5(1928).—This product consists of a potato alc. aromatized with various herbs. Analysis of an authentic sample gave: alc. 42.0% by vol., total acidity 0.228 g. per l., non-volatile acidity 0.090 g. per l. (32.8 mg. % of abs. alc.), aldehydes 8.2 mg., esters 29.9 mg., higher alcs. 36.7 mg., total non-alc. volatile matter 107.6 mg. % of abs. alc. A. PAPINEAU-COUTURE

Rice beer (sake) in Japan. E. HUBER. *Allgem. Brauer- u. Hopfen-Ztg.* **67**, 1248–9; *Chem. Zentr.* **1927**, II, 2428; cf. *Allgem. Brauer-u. Hopfen-Ztg.* **67**, 1108, 1112–3, 1135–6, 1163–4, 1215–6, 1220–1.—*Midzuame* is a very old beverage which is still made only in a few remote parts of Japan. It is apparently a transition form from the old millet beer to the Chinese rice beer. The % compn. of midzuame is: water 13.02;

protein 0.26, maltose 53.03, dextrin 31.85, ash 0.15, fat and insol. 0.79. The % compn. of Japanese rice beer is: EtOH 3.04–4.60, ext. 5.06–5.85, maltose 0.77–1.73, protein 0.45–0.53, acids 0.077–0.161, ash 0.186–0.240, H_3PO_4 0.051–0.72. C. C. Davis

W. O. EMERY

Calabrian myrtle oil. Anon. *Riv. ital. essenze e profumi* **22,** No. 4, 10(1928).—*Myrtus communis* Lin grows spontaneously and abundantly in Calabria. The dried leaves are used in *tanning leather.* By steam distg. the leaves there is obtained a green-yellow essential oil, pleasant odor, d. 0/.9044–0/.911, α_{15} 21° 12′ – 22° 48′, n_{20} 1.465–1.467, acid value 1.8–2, ether value 72.8–85.87, ethers after acetylation 11.00–12.53, myrtenol 14.24–16.86, total alc. 34.00–40.16, soly. in alc. 80° 1:5–1:3.5, yield in essence 0.19–0.22%. R. Sansone

A color standard for tincture of cudbear, N. F. L. F. Cabel. *J. Am. Pharm. Assoc.* **17,** 148–9(1928).—Occasionally a sample of cudbear is encountered, the tinctorial power of which is below the av. Six lots of tincture were prepd. from as many specimens and a composite tincture was prepd. as a standard. The color was matched by a soln. contg. 0.9 cc. of 0.1 *N* $CoCl_2$, 3 cc. NH_4 carbonate test soln., 0.7 cc. 0.005 *N* $K_2Cr_2O_7$ and H_2O to make 10 cc. added in the order named. The matching of unknown tinctures is made in the usual way by dilg. The color of the dild. tincture fades so that the matching must be done with solns. on the day the dilns. are made.
L. E. W.

Calculation of alcohol in tinctures. F. Wratschko. *Pharm. Presse* **33,** 202–4, 216–9(1928).—In a recent address W. discusses the formula:

$$d_a = \frac{100d - x(a + 1.5x)/10^3}{(100 - x)/2},$$

in which d_a = density of alc. used in prepg. tincture, x = % of dry residue, d = d_{15}^{15} of the tincture, and a = an individual const. which in general equals 0.79. Exceptions are found in Tinct. Gallarum (a = 0.84), tinctures of the gums benzoin, myrrh, asafetida and amber (a = 0.65), and of certain seeds (a = 0.65 to 0.70). The data obtained by recent workers in this field (d., refractive index and dry residue) have been utilized in

the above formula in calcg. the indicated values of some 40 different tinctures, all the results being tabulated. W. O. E.

Russian & ethereal oils. A. CHERNUCHIN. *Oil & Fat Industry* (Russia) **1927**, No. 3–4 57–60; *Chem. Zentr.* **1927**, II, 2122.—A study of the oil from *Mentha piperita* showed that the best yield of oil and the highest menthol content are obtained from the partly bloomed plant. Fully bloomed plants give the poorest yield of oil with the lowest menthol content. To purify the oil, it is recommended that it be shaken with freshly pptd. $Al(OH)_3$. After standing 3–5 hrs. and filtering, an almost colorless oil is obtained. C. C. DAVIS

The determination of ethereal oils in drugs. J. STAMM. *Pharmacia* **1926**, No. 5, 5 pp.; *Chem. Zentr.* **1927**, II, 1519–20; cf. *C. A.* **22**, 3486.—The method is further developed by a supplementary detn. of the "*true content*" of ethereal oils in the drug. To det. this true content, there must be first detd. the quantity of ethereal oil which under the same conditions must be distd. with water in order to obtain the same yield as the yield of oil from the drug. This detn. was also made with the oleometer. The quantity of oil must not exceed the capacity of the oleometer. 0.15, 0.14, 0.13 .... 0.1-cc. portions of oil were distd. with 250 cc. of water and a table of yields was compiled. The no. corresponding to the yield of oil from the drug was detd. from the table and from this the quantity of oil used in the distn. The "true content" of ethereal oil in the drug must correspond to this quantity. Satisfactory results were obtained with *Fructus anisi, Folia rosmarini, Herba thymi, Folia menthae piperitae* and *Fructus carvi.* C. C. D.

Determination of the "true content" of ethereal oil in drugs by the method of Stamm, using a butyrometer. ERNST JAGERHORN. *Pharmacia* **1926**, No. 5, 7 pp.; *Chem. Zentr.* **1927**, II, 1520.—Instead of using the oleometer of Stamm (cf. preceding abstr.) the original butyrometer of Gerber was utilized. Here too the loss of CCl_4 was 1 graduation mark and was added at the end. The most ethereal oil was obtained from the drug in powder form, the least from the whole drug. Small quantities, *e. g.*, 5 g , yielded relatively more oil than large or very small quantities, *e. g.*, 2 g. *Fructus foeniculi, Herba majoranae* and *caryophylli* gave greater yields of ethereal oils and *Fructus anisi* and *carvi* gave smaller yields than the yields which are recorded in the literature. The true oil content of *Cortex cinnamomi chin.* could not be detd. because under the conditions the cinnamon oil could not be distd. without leaving a residue. C. C. D.

Method for the determination of ethereal oils in drugs, according to Stamm. EINO TIKKANEN. *Pharmacia* **1926**, No. 5, 3 pp.; *Chem. Zentr.* **1927**, II, 1520; cf. preceding abstr.—The yields of oil from various drugs were detd. by the oleometer method of Stamm (without regard to the true oil content) to ascertain the precision of the method. All detns. of the same powdered drug agreed precisely with one another and gave excellent values. The data are recorded in tables. The procedure can be carried out in 1.25 hrs. and costs very little. C. C. DAVIS

The composition of strychnine phosphomolybdate. C. ANTONIANI. R. Istituto Superior Agrario, Milano. *Giorn. chim. ind. applicata* **10**, 408–10(1928).—In completion of expts. on the detn. of P_2O_5 by the use of strychnine molybdate (cf. *Giorn. chim. ind. applicata* **10**, 203 (1928)), the compn. of the ppt. was detd. The best conditions for its sepn. are with 350 parts of MoO_3, 2500 parts of HNO_3 and 10 parts of strychnine nitrate per 1 part of P_2O_5. It is advisable to wash the ppt. with 10% HNO_3. Under these conditions the *compn. of the strychnine phosphomolybdate* was $11MoO_3.H_3PO_4.(C_{21}H_{22}N_2O_2)_3.2HNO_3$. C. C. DAVIS

Fluorescence and some experiments with the analytical quartz lamp. ARNO MÜLLER. *Riechstoffind.* **1927**, 139–41; *Chem. Zentr.* **1927**, II, 2123.—Expts. with the Hanau analytical quartz lamp show that it is of no value in judging the purity of ethereal oils and synthetic perfumes, since the fluorescent colors of these substances are often identical in spite of their varied nature, and since their mixts. differ little from the individual substances. The results of numerous expts. are compiled in tables. C. C. DAVIS

Measurement of odor and its practical application. A. ROSENTHAL. *Riechstoffind.* **1927**, 142–43, 150–1, 161–2; *Chem. Zentr.* **1927**, II, 2123; cf. *C. A.* **22**, 138.—A method was developed for detg. whether one perfume has a more powerful odor than another and if so how much more powerful it is. An 0.88% soln. of the perfume in diethyl phthalate was dild. progressively with more diethyl phthalate until the odor was no longer distinguishable. The results of the comparative expts. are compiled in tables. C. C. DAVIS

The fixation problem. K. T. KELLER. *Riechstoffind.* **1927**, 144, 152–3; *Chem. Zentr.* **1927**, II, 2123.—A discussion of natural and artificial fixing agents, with reference to their action and their applicability in the *perfumery industry,* special attention being given to the resins of Schimmel & Co. C. C. DAVIS

Resins and resin products in perfumery. A. M. BURGER AND I. CLEMENTE. *Riechstoffind.* **1927,** 149–50, 162–3, 175–6; *Chem. Zentr.* **1927,** II, 2360.—Natural resins, balsams and oleoresinoids obtained from these products are described in detail, with special reference to their use in the *perfumery industry* and in the *manuf. of toilet soaps.* C. C. DAVIS

Investigation of thuja oils from the Caucasus. B. RUTOVSKII AND K. GUSSEVA. Chem.-Pharm. Research Inst., Moscow. *Reichstoffind.* **1927,** 185; *Chem. Zentr.* **1927,** II, 2723; cf. Rutovskii, Winogradowa and Koslov; *Chem. Zentr.* **1926,** I, 1306.—Fractionation of an oil of *Thuja occidentalis* yielded α-pinene, α-thujone (which readily isomerizes to β-thujone), fenchone and several esters. Oil from the leaves of *Th. varreana* had d_{20} 0.9078, α_D —1.23, n_D^{20} 1.4550, acid no. 1.5, ester no. 16.36, ester no. after acetylation 30.36, and yielded sabines, α-thujone and thujyl alc. From the twigs of *Th. gigantea var. sempcraurea* was obtained a 3.07% yield of oil, with d_{20} 0.9145, α_D —1.21°, n^{20} 1.4552, acid no. 2.34, ester no. 26, ester no. after acetylation 47.15, and contains α-thujone, α-pinene and thujyl alc. C. C. DAVIS

Methods of testing spermaceti according to the directions of some pharmacopeias. BOLESLAW OLSZEWSKI. Univ. Warsaw. *Roczniki Farmacji* **4,** 131–5; *Chem. Zentr.* **1927,** II, 1599.—Only tests of the acid no., sapon. no. and I no. are reliable, detns. of the alc. content and of the d. being of no value. C. C. DAVIS

Determination of the total geraniol in Java oil of citronella. SCHIMMEL & CO. *Schimmel & Co. Ann. Rept.* **1927,** 21; *Chem. Zentr.* **1927,** II, 1519.—To avoid discordant results, very precise and uniformly executed work is necessary. The use of Ac_2O more concd. than 85% and of completely dehydrated Na_2CO_3, acetylation for 2 hrs. and sapon. for 2 hrs. are indispensable. C. C. DAVIS

Adulteration of ethereal oils and natural perfumes. SCHIMMEL & CO. *Schimmel & Co. Ann. Rept.* 1927, 43–4, 48, 56, 64, 90, 93–4, 137–8, 144; *Chem. Zentr.* **1927,** II, 1519.—A continuation of publications and reports on cases of adulteration. *Birch bud oil.*—This was adulterated with Me salicylate, cedar oil and Et phthalate. *Bitter almond oil.*—A crude grade of BzH contg. Cl was sold for this oil. *Lemon oil.*—In 1 case this was adulterated with 6% of EtOH and 50% of lemon oil terpenes, in another case with 20% of mineral oil. *Eucalyptus oil.*—A "guaranteed 100% pure" grade was chiefly terpineol. *Cherry laurel oil.*—This consisted for the greater part of artificial BzH contg. Cl, but no HCN. *Lavender oil.*—This consisted of spike oil contg. Et phthalate. *Rose oil.*—Artificial esters were found. *Sandalwood oil.*—East Indian oil in some cases contained Et phthalate and Et benzoate, while 1 sample was composed almost wholly of cedar oil and another sample contained a mineral oil volatile with steam. *Juniper berry oil.*—This was apparently adulterated with nutmeg oil. *Geraniol.*—Grades marked "superfine," "100%," and "1A fine" left much to be desired in quality. *Liquid thymol.*—This was composed entirely of thyme oil or partly of carvacrol. C. C. DAVIS

Oil from Geranium macrorrhizum. SCHIMMEL & CO. *Schimmel & Co. Ann. Rept.* **1927,** 114, 115; *Chem. Zentr.* **1927,** II, 1519.—The odor of the oil obtained from a plant which grows wild and is also cultivated (chiefly in Bulgaria) resembles iris oil or muscatel sage oil. It has a soft, cryst., paraffin-like consistency, m. 25–35°, d_{15} 0.9431–0.9638, α_D —5°45′ to —7°38′, n_D^{20} 1.50642–1.51538, acid no. 1.2–1.5, ester no. 5.6–14.9, ester no. after acetylation 33.6–35.5, sol. in 6–7 vols. of 80% EtOH (slight turbidity) miscible in all proportions with 90% EtOH, contains 50% of a compd. of the nature of an oxide, which m. 54–5°. After sepn. of the solid components, the oil had d_{15} 0.9460, α_D —8°10′, n_D^{20} 1.50698, ester no. after acetylation 54.1, and was sol. in 0.5 vol. of 90% EtOH, while with more than 1.5 vols. there was a sepn. of paraffin. C. C. DAVIS

Castoreum. SCHIMMEL & CO. *Schimmel & Co. Ann. Rept.* **1927,** 135; *Chem. Zentr.* **1927,** II, 1519.—Steam-distn. of 4.810 kg. of castoreum from Canada yielded 2.1% of oil, about 0.5 of which was composed of phenols. The phenolic part contained *o-cresol* and a *phenol* $C_{15}H_{14}O_2$, while the part from which the phenols had been sepd. contained acetophenone, benzyl alc. and *l*-borneol. C. C. DAVIS

Synthetic menthol. SCHIMMEL & CO. *Schimmel & Co. Ann. Rept.* **1927,** 139; *Chem. Zentr.* **1927,** II, 1519.—A menthol was synthesized which m. 35° and in appearance and odor could not be distinguished from menthol obtained from peppermint oil. The phys. properties of the synthetic product were intermediate between those of artificial racemic menthol from thymol or piperitone and natural *l*-menthol. C. C. DAVIS

Synthesis of amino alcohols from isosafrole, isoeugenol and anethole. C. MANNICH AND FRIDA SCHMITT. *Arch. Pharm.* **266,** 73–84(1928).—Since the benzoate of

1-(3,4-methylenedioxyphenyl)-1-dimethylaminopropane-2-ol (I) (Mannich, *C. A.* **4**, 1044) has been shown to possess powerful, but weakly toxic, anesthetic properties, compds. were prepd., by the action of Me_2NH, Et_2NH and $C_5H_{10}NH$, resp., on the dibromides of isosafrole, isoeugenol methyl ether and anethole, in the hope of developing pharmacologically superior products. While the results hoped for were not realized, 9 new alc. bases were obtained, which were volatile in vacuum mostly as thick sirups, crystg. in part only after long standing. The alc. base arising from the interaction of $C_5H_{10}NH$ on isoeugenol methyl ether decompd. on distn. Since these alc. bases possess 2 asym. C atoms, 2 stereoisomeric *dl*-forms are possible in each case. Their acylation with BzCl and p-$O_2NC_6H_4COCl$ progresses for the most part smoothly; in certain cases, however, secondary reactions tend to lower the yield. With (I) a better yield than heretofore (about 70%) was realized, this compd. m. 66–8° and b_{16} 178–82°. On heating the *methiodide* (m. 176°) with KOH, it decompd. into Me_3N and isosafrole oxide, a behavior likewise noted in other reactions, like acylation. Thus, in prepg. the *benzoate* (m. 80–3°, *HCl salt* m. 202–8°), a *by-product* m. 164–5° was isolated in the form probably of the benzoate of *1-(methylenedioxyphenyl)-1-chloropropane-2-ol*, $C_{17}H_{15}O_4Cl$. The *p-nitrobenzoate* of (I) (*HCl salt*, $C_{19}H_{20}N_2O_6$.HCl, m. 223°) and p-aminobenzoate, $C_{19}H_{22}O_4N_2$, m. 120° are both anesthetics. *1-Diethylamino-1-(3,4-methylenedioxyphenyl)propan-2-ol*, b_{14} about 175° (*HCl salt*, $C_{14}H_{21}O_3N$ HCl, m. 196°); *benzoate* (*HCl salt*, $C_{21}H_{25}O_4N$.HCl, m. about 185°, powerful anesthetic) (*HCl salt*, $C_{14}H_{21}O_3N$.HCl, m. 196°); *benzoate* (*HCl salt*, $C_{21}H_{25}O_4N$.HCl, m. 185°, powerful anesthetic); p-nitrobenzoate (*HCl salt*, $C_{21}H_{24}O_6N_2$.HCl, m. 220°). Oxidation of the amino alc. with CrO_3 in AcOH lead to the formation of 3,4-methylenedioxybenzyl methyl ketone, m. 87–8°. *1-Piperidyl-1-(3,4-methylenedioxyphenyl)propan-2-ol*, $C_{15}H_{21}O_3N$, b_{16} 235–40°, m. 77°; *benzoate* (*HCl salt*, $C_{22}H_{25}O_4N$.HCl, m. 204° (decompn.) strongly anesthetic). 1-Dimethylamino-1-(3,4-dimethoxyphenyl)propan-2-ol, m. 51° (Mannich, *l. c.*); *p-nitrobenzoate* (*HCl salt*, $C_{20}H_{24}O_6N_2$.HCl, m. 198°). *1-Diethylamino-1-(3,4-dimethoxyphenyl)-propan-2-ol*, $C_{15}H_{25}O_3N$, b_{14} 197–9°. *1-Piperidyl-1(3,4-dimethoxyphenyl)propan-2-ol*, crude base, b_{14} 212–20°, decompg. into $C_5H_{10}NH$ and 3,4-dimethoxybenzyl methyl ketone. 1-Dimethylamino-1-p-anisylpropan-2-ol, b_{17} 162°, m. 39° (*HCl salt*, $C_{12}H_{19}O_2N$.-HCl, m. 195°); *p-nitrobenzoate* (*HCl salt*, $C_{19}H_{22}O_5N_2$.HCl, m. 205° (decompn.)); *p-aminobenzoate*, $C_{19}H_{24}O_3N_2$, m. 159°, in dil. HCl strongly anesthetic. *1-Diethylamino-1-p-anisylpropan-2-ol* (*HCl salt*, $C_{14}H_{24}O_2NCl$, very hygroscopic), b_{20} 210°. *1-Piperidyl-1-p-anisylpropan-2-ol*, $C_{15}H_{23}O_2N$, b_{14} 203–5° (*HCl salt* m. 180°); *p-nitrobenzoate* (*HCl salt*, $C_{22}H_{27}O_5N_2Cl$, m. 213° (decompn.)). While the above-described amino alcs. should represent mixts. of stereoisomerides, there is considerable doubt whether this is the case since the cryst. representatives do not appear to be mixts. W. O. E.

Physical constants of bromoform. H. Buhmann. Univ. Göttingen. *Arch. Pharm.* **266**, 123–5(1928).—Of two samples of pure $CHBr_3$ examd. one had d_4^{15} 2.9000, b_{760} 146.3°, solidifying at 7.5°, the other b_{760} 147.2°. The latter mixed with 1% of abs. EtOH had $d_{15.5}^{15.5}$ 2.8161, b_{760} 146.6°, solidifying at 5.4°. While this sample fulfils the Ger. Pharm. requirements, the official method for its evaluation is unsatisfactory. The use of a Schantz app. is advisable in detg. the proportions volatile between the prescribed limits. W. O. E.

Note on the preparation of magnetic oxide of iron. Wilfred H. Linnell. *J. Pharm. Soc.* **1**, 178–81(1928).—Fe_3O_4 has not been obtained, but hydrates contg. as much as 17% of potential ferrous Fe have been prepd. A method is given showing the optimum concns. of reactants and precipitants previous to pptn. The ppt. should be boiled until it becomes black (10 min.). Prolongation of boiling causes oxidation. Temp. of drying should not exceed 75°, but after the product is dried it appears to be stable even at red heat. Better results were obtained by using NaOH as precipitant than with NH_4OH. The work is being continued in order to det. the conditions necessary to produce hydrated ferroso-ferric oxides of definite chem. constitution. W. O. E.

Constitution of tartar emetic and scale preparations. I. Wilfred H. Linnell and Catherine Tickle. *J. Pharm. Soc.* **1**, 194–9(1928).—While the present communication is mainly historical, certain preliminary expts. are reported or under way. Thus, the behavior of tartar emetic itself with various methylating agents is being examd. to see if a deriv. contg. Sb can be formed. Expts. are also being made, using $Fe(OH)_3$ in place of Sb_2O_3, to det. whether the formation of a scale prepn. can be regarded as a parallel to the formation of an emetic. Touching the interaction of diethyl tartrate and freshly pptd. $Fe_2(OH)_6$ and Sb_2O_3, resp., it appears that reaction occurs, but in the latter case at any rate is confined to hydrolysis of the ester, no combination between the ester and oxide occurring. Results from expts. in dialysis of scale prepns. lead to the conclusion

that $Fe(OH)_3$ is simply held in soln. in the scale prepn. and that no combination obtains between the hydroxy acid and the Fe. W. O. E.

Notes on the evaluation of syrupus simplex with Fehling solution. FRITZ WISCHO AND LUDWIG ZECHNER. Univ. Graz. *Pharm. Monatsh.* **9**, 191–3(1928).—Very important in applying the Pharm. Fehling test is a consideration of the fact that practically every simple sirup contains a certain amt. of invert sugar, which falls below the Pharm. limit of sensitiveness. W. O. E.

Comparative examination of different commercial grades of cardamom. W. OTTE AND H. WEISS. Hygien. Inst. Hamburg. *Pharm. Zentralhalle* **69**, 613–6(1928).—The entire fruit, the seed capsules and the ground entire fruit have been made the subject of study. The results obtained are tabulated. W. O. E.

Reactions of novocaine and its differentiation from cocaine, alypine, holocaine and stovaine. LAD. EKKERT. Univ. Budapest. *Pharm. Zentralhalle* **69**, 616–7(1928).—Novocaine yields in alk. soln. with I iodoform; furthermore, with $ZnCl_2$ as also with *p*-dimethylaminobenzaldehyde and H_2SO_4 it gives a yellow to a dichromate-red color; likewise with furfural-H_2SO_4, furfural-H_3PO_4 and with furfural alone violet-red to purple-red color tones develop. Comparative tests with cocaine, β-eucaine, alypine, holocaine and stovaine indicate that the above behavior of novocaine is characteristic, and may be used as a means of identification. W. O. E.

Preparation of phenylcinchoninic acid. F. CHEMNITIUS. *Pharm. Zentralhalle* **69**, 549–51(1928).—One of the procedures for prepg. this compd. involves condensation of $AcCO_2H$ with PhCH:NPh. Detailed methods are outlined for the prepn. of these 2 substances, and their subsequent condensation to phenylcinchoninic acid. W. O. E.

Cocaine. P. MARTELL. *Pharm. Zentralhalle* **69**, 551–6(1928).—A description of the culture of *Erythroxylon coca* Lam. as carried on notably in S. American countries, in connection with the use of the leaves by Indians and whites, and the results of such use and the consumption of cocaine on the animal economy. W. O. E.

Pharmaceutical science in its relationship to the pharmaceutical-chemical industry. HERMANN THOMS. Berlin. *Apoth. Ztg.* **43**, 995–6(1928).—Discursive. W. O. E.

Microchemistry of alkaloids. HANS BECKMANN. *Pharm. Ztg.* **73**, 1165–6(1928).—Simple manipulations and app. are described for the identification (through sublimation, crystn. and color tests) of some 18 alkaloids and materials contg. them. Critical mention is made of the official Ger. methods. W. O. E.

Preparation of sodium salicylate tablets. I. G. OBERHARD. *Pharm. Ztg.* **73**, 1212(1928).—The article is a reply to a request for a suitable formula for compounding these tablets, notably with reference to the desirable vehicular matter contained therein. W. O. E.

Pharmacological evaluation of digitalis specialties. G. JOACHIMOGLU. Univ. Berlin. *Pharm. Ztg.* **73**, 1212–3(1928).—The examn. of 6 different com. samples of digitalis prepns. clearly indicates the necessity for the official control of such medicaments. W. O. E.

Characterization of homeopathic preparations. H. NEUGEBAUER. *Apoth. Ztg.* **43**, 1209–11(1928).—The microchem. evaluation of varying potencies of $K_2Cr_2O_7$, As_2S_3, tartar emetic, metallic Bi and Bi subnitrate is discussed. W. O. E.

Estimation of the condurangin content of condurango bark. HUGO WAGNER. Univ. Graz. *Pharm. Monatsh.* **9**, 189–91(1928).—The present study is an amplification of the recent work by Zechner, Wischo and Wagner (cf. *C. A.* **22**, 2637) on the subject. The procedure followed is described in detail, and the results obtained are tabulated. W. O. E.

Microchemistry of Illicium verum Hook. and Illicium religiosum Sieb. EDITHA SIERSCH. Univ. Wien. *Pharm. Zentralhalle* **69**, 581–5, 601–5(1928).—The carpels of both species of *Illicium* contained sikimmic acid, in much greater quantity in *I. religiosum* than in *I. verum*, thus confirming the findings of Eykman. The seeds of neither plant contain this acid. By means of various solvents a cryst. substance was extd. from *Illic. relig.*, the chem. compn. of which could not on account of the minute quantity be detd. The prepn. of sikimmin *via* Eykman was repeated with the result that minute quantities of a crystn. substance were isolated which had similarity to the sikimmin of Eykman (from *Illic. relig.*). For the differentiation of toxic from non-toxic fruits, Rosoll's saponin test was made on the fruit of *Illic. verum*, with the result that this test, while in many cases of value, cannot be considered absolutely reliable. A microchem. study of the Combes saponin test as applied to both *I. verum* and *I. religiosum* leads to the conclusion that both plants contain a saponin. Attention is directed to various contradictions in the literature relative to *Illic. relig.* Siebold and *Skimmia japon.* Thung. and their recognition. W. O. E.

New liver-fluke remedies. NEUMAN WENDER. *Pharm. Ztg.* **73,** 968–9(1928).—In treating the serious disease of the liver in cattle, sheep and goats, caused by the liver fluke *Fasciola hepatica* (termed *Distomum hepaticum* by W.), recourse was formerly had to male fern ext. and *Kamala;* more recently to prepns. of CCl_4, hexachloroethane, either alone or with male fern ext. W. O. E.

Amomis caryophyllata, Kr. et Urb., and the production of bay rum. KAREL DOMIN. *Časopis Československého Lékárnictva* **7,** 210–21(1927).—A comprehensive review. WILLIAM J. HUSA

Some notes on pharmaceutical analysis. O. TOMÍČEK AND ADOLF JÁNSKÝ. Charles Univ., Prague. *Časopis Československého Lékárnictva* **7,** 313–9(1927).—A discussion of the application of electrometric titration in pharmacy, with examples of the use of this method in analysis of "Sedobrol" (a prepn. contg. Na halides and other substances), and in the indirect detn. of some alkaloids in triturates. WILLIAM J. HUSA

Emulsions and their preparation. E. ISELIN. *Boll. chim. farm.* **67,** 225–8 (1928).—For the prepn. of 100 g. of stable oil-in-water emulsions the following min. amts. of 0.1 *N* NaOH are required per 20 g. oil: olive oil 10–15 cc., cod-liver oil 5 cc., castor oil 10 cc. The emulsions are not perfectly stable; the max. emulsification is established only after a few days. Cod-liver oil gives the best emulsions because of its content in free fatty acids. The Na ions tend to ppt. the droplets. The castor-oil emulsion is less good and owes its stability only to its greater viscosity. The addn. to the oil of 10–2.5% oleic acid increases the stability of the emulsions; however, they cannot be given internally because of the hemolytic effect of oleic acid. Stable water-in-oil emulsions are obtained with the following min. amts : For olive oil 22.4 cc. lime water, or 10 cc 0.1 *N* $Ca(OH)_2$ ($Ba(OH)_2$), for cod-liver oil 33.6 and 15 cc., for castor oil 22.4 and 10 cc. These emulsions are of salve consistency and sep. neatly from the aq. layer, showing that there is no oil emulsified in the water. They are easily coagulated by excess alkali. Emulsification is favored by gelatin or, better, gum arabic. To 25 g. *castor oil* heated on the water bath add a mixt. of 15 cc. lime water and 10 g. acacia mucilage, stir, cool and triturate in a mortar with 1.5 g. gum arabic. To 1.5 g. melted palmitic acid add 8 g. *N* KOH and dropwise with stirring 20 g. acacia mucilage, a soln. of 0.5 g. gelatin in 40 cc. water and a hot mixt. of *cod-liver oil* with 30 g. sirup. Palmitic acid was chosen because of its beneficial physiol. action. I. discusses Adam and Matthews' and Hildebrand's views on emulsification. Hildebrand's theory is borne out by expt. Cs, K, Na and Ag form oil-in-water emulsions, the degree of emulsification decreasing with the atomic vol. in the above order. Ca, Mg, Zn, Al and Fe form water-in-oil emulsions, the stability of which increases inversely with the atomic vol. M. J.

Lavender. VITTORIO NIGRISOLI. *Boll. chim. farm.* **67,** 298–302(1928).—Compn., properties, uses and production of lavender oil are discussed. MARY JACOBSEN

Physical constants and assay of some camphor preparations. A. JERMSTAD. *Boll. chim. farm.* **67,** 302–3(1928); cf. *C. A.* **22,** 1824.—The best method of detn. of camphor in spirits of camphor is by isolating and weighing. To 10 cc. of the alc. soln. in a 200-cc. separatory funnel add a mixt. of 4 parts satd. NaCl and 1 part water, shake vigorously 5 min. and allow to stand 15 min. Shake the aq. layer out with 20 cc. ether, and shake the combined ether solns. vigorously with 15 cc. of the NaCl soln. Transfer the ether layer to a 100-cc. Erlenmeyer flask contg. 5 g. Na_2SO_4, rinse the funnel with ether to make up the soln. to 40 cc., and allow to stand overnight. Weigh 20 g. of the soln. into a 50-cc. flask, evap. about 80% of the ether on a gently heated water bath, then dry in a vacuum desiccator to const. wt. The residue ought to consist of pure camphor. A table gives the d., n and α of camphor oil and spirits of camphor. MARY JACOBSEN

The color reactions of lecithin. D. MIGLIACCI. *Boll. chim. farm.* **67,** 324–5 (1928); cf. Ekkert, *C. A.* **22,** 1651.—Tabulated color reactions of lecithin with furfural, sucrose, BzH, salicyl and anisyl aldehydes, vanillin and piperonal at the zone of contact with concd. H_2SO_4 and after shaking. MARY JACOBSEN

Saffron substitutes in Sidenham's laudanum. ANGELO ANGELETTI. *Giorn. farm. chim.* **76,** 37–40(1927).—The common adulterants and substitutes of saffron are marigold, safflower, curcuma, sandalwood or coal tar dyes. Two cc. of laudanum is treated with 20 cc. water and shaken out with 10 cc. AmOH. The evapn. residue, contg. the dye and traces of narcotine, papaverine and meconic acid, is treated successively with concd. H_2SO_4, HNO_3, HCl and NH_3. A table gives the color reactions of saffron and adulterants. Coal-tar dyes, red sandalwood and curcuma are also extractable with ether. MARY JACOBSEN

Chemical assay of ergot. ALBINA DIAMONTE. *Giorn. farm. chim.* **76,** 127–30 (1927); cf. Goris and Liot, *C. A.* **18,** 3220.—Ergot powder contg. 0.304% alkaloids was

extd. with water-$CHCl_3$ with and without tartaric acid directly (I) and after autoclaving in alc. (II). The assay was made by Goris and Liot's silicotungstate method. The acidulated I contained 0.071% alkaloids, the $C_4H_6O_6$-free I 0.065%. The content of II was slightly lower. Stabilization of ergot is useless at least in the case of dried ergot, which has probably already undergone enzymic decompn. The present method of extn. is very unsatisfactory. MARY JACOBSEN

Sterilization of catgut. E. BARONI. *Giorn. farm. chim.* **77,** 130–42(1928).—Description of Claudius' I sterilization followed by autoclaving in alc. at 0.5 atm. MARY JACOBSEN

Chemical and biological assay of digitalis ambigua. ISIDE SCAGLIOLA. *Giorn. farm. chim.* **76,** 197–201(1927); cf. Burmann, *C. A.* **6,** 1494; *J. pharm. chim.* **1915,** 33.—The digitalin content (Keller-Ecalle) was 0.078%. The m. l. d. (1-hr. frog method) was 133% of that of *Digitalis purpurea.* MARY JACOBSEN

The sensitiveness of Otto's reaction for strychnine. LEONARDO BELTRAN AND ALBERTO IBARRA. *Quim. ind.* **5,** 137(1928).—With the usual technic and a 0.01 satd. soln. of $K_2Cr_2O_7$ the sensitiveness is 1:150,000. If the ppt. is dried with filter paper the sensitiveness is reduced to 1:110,000. MARY JACOBSEN

Home-grown rhubarb. M. RUSZKOWSKI. *Bull. pharm. Inst. Poland* **1928,** No. 1, 1–16.—Chinese (Shenzi) rhubarb (I) thoroughly pulverized gives on extn. with abs. alc. in the Soxhlet app. 61.53% ext, whereas the different species of rhubarb (II) cultivated in Poland between 1918 and 1922 gave 17.70–20% ext. On extn. of I and II with ether 15.45% and 4.40–6.53% exts., resp., contg. mainly hydroxymethylanthraquinone were obtained. JAROSLAV KUČERA

Simple and quick micro methods for tobacco analysis. I. Microtitrimetric determination of nicotine. J. BODNÁR, JOHANN STRAUB AND VITÉZ LADISLAUS NAGY. *Biochem. Z.* **195,** 103–17(1928).—To 10 cc. of an ether-petroleum ether soln. of nicotine are added 10 cc. 0.01 *N* HCl, 10 cc. H_2O and a drop of methyl red (prepd. by adding 0.01 *N* NaOH to the solid dye until only a small quantity remains undissolved) and the titration is made with 0.01 *N* NaOH under vigorous stirring until a yellow color appears. One cc. 0.01 *N* HCl is equiv. to 1.62 mg. nicotine. Another procedure is to set free the nicotine from 1 g. tobacco powder with 1 g. $Ca(OH)_2$ and to ext. the nicotine with toluene instead of ether-petroleum ether mixt. and titrate as before. S. MORGULIS

Galenical valerian preparations. E. H. MADSEN. *Dansk. Tids. Farm.* **2,** 177–83 (1928).—In valerian roots the active principle is present in amts. from 0.5 to 1% and consists chiefly of bornyl valerate, bornyl formate, acetate and butyrate, *l*-pinene, *l*-camphene, etc., in addn. to a variable amt. of free valeric acid. During drying the alkyl salts sep. and free valeric acid is formed. In fresh (green) roots no valeric acid is present. Some concd. valerian prepns. intended to give by simple diln. a product similar to infusions were examd. and the oil content of the prepns. was estd. A prepn. 1:3 made by suitable percolation with 10% alc. seems to be suitable for this purpose; it contained 20.6% of the oil of the root, whereas simple infusion contained 16.7%. Pilular exts. made by the method of Dutch Pharm. and by a method whereby the oil was removed by steam distn. and afterwards mixed with the ext. contained approx. 50% of the oil. The aq. layer from oil distn. must be used afterwards for extn., as it contains much oil. M. Lind in discussing M.'s lecture stated that valerian roots grown in warm dry weather have a higher oil content, but a lower ext. content than roots grown in cold wet weather, in which the conditions are just the reverse. C. Schousen mentioned that contrary to certain discussions relative to the repercolation method for valerian roots, C. Lewis Diehl's repercolation method (Ph. U. S. A. 1926) gives good results. O. A. NELSON

Determination of morphine in aqueous solutions. H. BAGGESGAARD-RASMUSSEN AND SVEND AAGE SCHOU. *Dansk. Tids. Farm.* **2,** 233–41(1928).—Take 20 cc. of soln. (corresponding to a morphine content of 0.1–0.2 g.) and shake with 3 vols. of $CHCl_3$ and 5 cc. of a 4% $NaHCO_3$ soln. in a separatory funnel. The vol. of extraction mixt. should be equal to the vol. of the aq. soln. As soon as the 2 liquids have sepd. after 1 min. shaking, draw off the org. layer as quickly as possible to prevent crystn. of morphine. Repeat the extraction twice more. Filter the combined ext., evap. to dryness on the H_2O bath, dissolve the residue in 10 cc. of 0.1 *N* HCl, if necessary, with gentle warming. Cool, add 15 cc. of H_2O, 2 drops of methyl red indicator soln., and 1 drop of a 1:1000 soln. of methylene blue. Titrate the excess acid with 0.1 *N* borax soln. until the color changes to green. Check analysis of aq. solns. of morphine salts of solns. contg. 10% tinct. coccinellae or 50% glycerol have given satisfactory results. O. A. NELSON

Present status of the evaluation of pyrethrum. J. CHEVALIER. *Ann. fals.* **21,**

318–23(1928); cf. *C. A.* **22**, 2433.—A discussion of the uselessness of chem. analysis as a method of detg. the activity of pyrethrum, with a plea for the adoption of a suitable biol. method of assay. A. PAPINEAU-COUTURE

Some British East African oils of geranium. L. S. GLICHITCH AND CHARLES MULLER. *Chimie & industrie* Special No., 478–81(April, 1928).—See *C. A.* **22**, 1016. A. PAPINEAU-COUTURE

Identification of cedrene by oxidation with permanganate. L. S. GLICHITCH AND R. NAVES. *Chimie & industrie* Special No., 482–3(April, 1928).—Cedrene-glycol prepd. *via* Semmler and Hoffmann (*C. A.* **2**, 106) and by the Chiris modification thereof (*C. A.* **19**, 2726) both had a m. p. 167.5–168° (Semmler and Hoffmann reported 160°). The former method gave only about 16% of the yield of the latter; but, contrary to what G. and N. had expected on account of the 8° difference in published m. p. by the 2 methods, the prolonged heating at high temp. in the Semmler and Hoffmann method does not cause a complete isomerization of the glycol during distn. A. P.-C.

The chemical constitution of various compounds having a musk odor. R. DELANGE. *Chimie & industrie* Special No., 484–95(April, 1928).—A review dealing with civetone, muscone, ambrettolide and the chief artificial musks. A. P.-C.

Citronellol and rhodinol. ANON. *Parfums de France* **6**, 234–40(1928). (In French and English.)—A review of the structural relationship between citronellol and rhodinol. A. P.-C.

Comparative determinations of the alkaloid content in drugs according to the testing procedures of the Finnish pharmacopeia and those of Dieterle. ERNST JÄGERHORN. *Farmaceutiskt Notisblad* **36**, No. 3, 6 pp.; *Chem. Zentr.* **1927**, II, 1061.—The drugs cortex Chinae (I), radix Ipecacuanhae (II), semen Strychni (III), opium (IV) and folia Belladonae (V) were tested for their alkaloid content according to the method given in the Finnish pharmacopeia V and by the method of Dieterle, which is designed for use with small quantities. The results were as follows: With I the two methods gave concordant results, even though $12^1/_2$ times less material was used in the second method. With II the second method gave a 0.61% higher value using 10 times less material; and III it gave 0.2% higher values using 15 times less material; with IV it gave 0.08% higher values using 23 times less material; and with V it gave 0.052% higher values using 4 times less material. J. S. REICHERT

The influence of alcohol on the decomposition of narcotic ether and testing the latter with phenolphthalein according to Stamm. EINO TIKKANEN. *Pharmacia* **1926**, No. 5, 7 pp.; *Chem. Zentr.* **1927**, II, 1496.—T. investigated the question as to how much alc. may be added to narcotic ether for preservation purposes and obtained the following results: "Kahlbaum" narcotic ether with 2% alc. decompd. in daylight as rapidly as ether free from alc.; an alc. content of 3% accelerated the decompn.; and 5% of alc. had an even greater decompg. effect. "Schering" narcotic ether with an alc. content of $^1/_2$, 1 and 2% decompd. more slowly than ether free from alc. The addn. of 1% alc. had the highest preservative action on ether. Ether with 3% alc. decompd. as rapidly as alc.-free ether and 5% alc. accelerated decompn. Both kinds of ether without alc. and with the addn. of up to 5% alc. showed no decompn. in the dark in 30 weeks. Narcotic ether should not contain more than 1% alc. If more alc. is needed for narcotic action it should be added immediately before using. For testing ether for H_2O_2 and dihydroxyethyl peroxide T. recommends only the phenolphthalein test of Stamm, and for AcH and vinyl alc. only the Nessler test, since neither is affected by the presence of alc. In this respect a change in the testing procedure is recommended for the Pharmacopeia. J. S. REICHERT

Notices on the oils of citronella. A. RECLAIRE. *Riechstoffind.* **1927**, 73–6; *Chem. Zentr.* **1927**, II, 1405; cf. *C. A.* **22**, 1346.—A comprehensive review on the types and sources; growth, harvesting and distn.; and methods of tech. analysis. Celebes citronella oil has the following properties: d_{15}, 0.8919–0.8950; α_D, —0.5 to —3.2°; n^{20}_D, 1.4691–1.4712; sol. in an equal vol. of 80% alc.; total geraniol, 85.1–92.6%; residue on distn. above 250°, 5.8–9.6%. J. S. REICHERT

The crystalline perfumes as fixators in the perfume industry. I. CLEMENTE. *Riechstoffind.* **1927**, 77–8; *Chem. Zentr.* **1927**, II, 1405.—A further discussion of methyl anthranilate, Me ester of methylanthranilic acid, naphthol ether, methyl cinnamate, benzyl cinnamate, diphenylmethane, diphenyl oxide, β-naphthyl methyl ketone, *p*-cresyl phenylacetate, phenethyl phenylacetate, phenethyl cinnamate and benzoyleugenol with reference to their use in perfumes. J. S. REICHERT

Concentrated lemon juice. GIOVANNI ROMEO. *Riv. ital. essense e profumi* **1928**, 20–1.—The perfume of lemon juice is due to citral and other aldehydes, to linalyl acetate, geranyl acetate and free alc. In commercial deterpenized lemon juice there are 40–

52% of citral and 16–20% of ethers. In qualities of guaranteed purity 63–67% citral and 15–16% ethers. Sesquiterpeneless lemon juice suffers during redistn., treatment with alc., etc., a loss in ethers. Because of its high content of citral and its rotatory power close to zero, sophistications are easy with mixt. of citral, lemongrass and other substances. The deterpenated product instead, has an accentuated levorotatory power (—5.00 to—8° 30′); it is difficult to imitate also through the presence of sesquiterpenes necessary for its levorotation. Sesquiterpenes are seldom found in commerce. Nor is it easy to find levorotatory products that can be substituted for sesquiterpenes. R. SANSONE

Choline content of the Danish insulin "Leo" and of vitamin B (American preparation). MARIA MAXIM. *Chem.-Ztg.* **52**, 711(1928).—On account of the observation that insulin injection is always accompanied by a blood-pressure reduction, M. analyzed samples of the Danish insulin "Leo" (5 cc. = international units) for choline. The qual. test with $PtCl_4$ in aq.-alc. soln. was positive; the quant. detn. as periodide gave 50.4 mg. choline per l. in one sample and 48.6 mg. in another. The choline content of an American vitamin B prepn. was 3.36 mg. %. G. SCHWOCH

Caswell Armstrong Mayo, 1862–1928. ANON. *Chemist and Druggist* **108**, 142 (1928).—Obituary, with portrait. Also see *Pharm. J.* **120**, 140, 238(1928). S. W.

The correlation of analytical data and accuracy in dispensing. P. A. W. SELF AND C. E. CORFIELD. *Pharm. J.* **120**, 144–8, 154–5; *Chemist and Druggist* **108**, 202–5 (1928).—The chief sources of discrepancies between the findings of the official analyst and practical accuracy in the compounding of medicines are: (*a*) Errors involved in measuring vols.; with small vols. the error may reach +8%. (*b*) The rigid single no. standards adopted by the Brit. Pharm., *e. g.*, for the strengths of dil. acids. The concd. Brit. Pharm. acids have fairly const. compn. between very narrow limits; the dil. acids prepd. from these by wt. show deviations of ± 5%; when dild. by vol., the errors are larger. The standard for strong $FeCl_3$ soln. is fixed at 20 g. Fe per 100 cc.; however, in 9 com. samples the % of Fe (wt./vol.) varied from 19.6 to 25.11% (d. 1.428–1.534). The Brit. Pharm. also fails to allow for deterioration of drugs in storage (cf. Evers, *C. A.* **20**, 2390), *e. g.*, by efflorescence, as with quinine sulfate which in 9 samples showed an av. gain in strength of 5% through loss of water. The adoption by the Brit. Pharm. of permissible limits of variation is urged. S. WALDBOTT

Antileprotic drugs. BURROUGHS, WELLCOME AND COMPANY. *Pharm. J.* **120**, 209(1928).—*Alepol* is a well-defined compd. so named to avoid confusion with the various Na hydnocarpates, chaulmoogrates, gynocardates, etc., of the market. It is a mixt. of Na salts of a fraction of the fatty acids of hydnocarpus oil, selected so as to retain the therapeutic efficiency of the salts of the total acids, but to be devoid of their irritant properties. S. WALDBOTT

Some reactions of pharmacology on pharmacy. H. H. DALE. *Pharm. J.* **120**, 245–50, 254; *Chemist and Druggist* **108**, 351–2(1928).—See *C. A.* **22**, 2637. S. W.

Narcotine sesquisulfate. D. B. DOTT. *Pharm. J.* **120**, 292, 301; *Chemist and Druggist* **108**, 451(1928).—When narcotine (*A*) is treated with H_2O and sufficient H_2SO_4 to form the normal salt, part of the alkaloid remains persistently undissolved. The addn. of half as much acid again effects complete soln. On evapn., a cryst. mass is formed which seems to have the compn.: $A_4.3H_2SO_4.6H_2O$. S. WALDBOTT

Some galenical preparations of the British Pharmacopeia. PETER BOA. *Pharm. J.* **120**, 292–3, 301–3; *Chemist and Druggist* **108**, 451(1928).—Sp. suggestions are made for the improvement or the elimination of certain galenical prepns. S. WALDBOTT

Notes on pharmacopeia revision; (a) podophyllum resin, (b) chrysarobin (c) assay of tincture of belladonna. D. B. DOTT. *Pharm. J.* **120**, 293, 301–3; ALFRED KING. *Ibid* 365; *Chemist and Druggist* **108**, 451–2(1928); cf. *C. A.* **22**, 2241.—(*a*) In the (implied) U. S. P. test for *emodi resin*, the proportion of KOH should be doubled so as to produce the required degree of gelatinization. The test should be adopted by the Brit. Pharm. (*b*) D. finds the soly. of chrysarobin (*A*) in alc., C_6H_6 and $CHCl_3$ to be, resp., 1:900, 1:70, 1:22; U. S. P. gives, resp., 1:385, 1:30, 1:13. These wide discrepancies are caused by difference of method in detg. soly. D. added solvent gradually until the substance was dissolved; in U. S. P. the substance in excess is shaken with a given vol. of solvent and an aliquot of the satd. soln. is evapd. Since *A* is a mixt. of compds. of varying soly., the U. S. P. method cannot give the true soly. of *A*. (*c*) In order to avoid emulsion of $CHCl_3$ with the concd. tincture, and formation of resinoid clots which occlude alkaloidal salt, evap. 100 cc. of Brit. Pharm. tincture to 40 cc., mix well with 2 g. kaolin, add 5 drops of AcOH and 70 cc. H_2O, mix well, break down the lumps, filter into a separator and wash the residue. Add 1–2 drops of tincture of cochineal, then sufficient NH_3 to alky., ext. with 4 portions of $CHCl_3$, filter, evap. and titrate with

0.05 *N* acid. K. proposes to shake out the green resinous matter with CS_2, which effects quick sepn., then to remove CS_2 with $CHCl_3$. The resulting soln. of the alkaloids is light brown, yielding a colorless, partly cryst. alkaloidal residue. S. WALDBOTT

Pharmacopeia revision: Reintroduction of Imperial weights and measures. HENRY STOUT. *Pharm. J.* **120**, 293–4, 301–3; *Chemist and Druggist* **108**, 452(1928).—A plea for the reintroduction of these wts. and measures, because of practical necessity; seconded in discussion. S. WALDBOTT

Pharmacopeia revision: The official liquors. GORDON PERRINS. *Pharm. J.* **120**, 294, 301–3; *Chemist and Druggist* **108**, 452–4(1928); J. R. Walmsley. *Pharm. J.* **120**, 364; Perrins, *Ibid* 439.—Suggestions for improvements of the official liquors, and deletion in some cases. S. WALDBOTT

Pharmaceutical education in Holland, with special reference to the University of Leiden. T. POTJEWIJD AND J. G. JONES. *Pharm. J.* **120**, 297–8(1928).—A description of the curriculum in pharmacy. S. WALDBOTT

Half a century of pharmacy (in London). T. H. POWELL. *Pharm. J.* **120**, 350–1, 369–71, 392–3(1928).—An autobiography, with historical notes. S. W.

West Australian sandalwood oil; a recent investigation. PERCY MAY. *Pharm. J.* **120**, 368–9(1928); cf. Marr, *C. A.* **22**, 138.—Tabulated results of analyses show that West Australian sandalwood oil is now obtainable of good standard quality, closely resembling the East Indian oil, and very different from the oil described by earlier authors. The alcs. in the oil show a striking similarity to the santalols of Mysore oil, but their identity is not fully established. Therapeutically the oil is in no way inferior to the East Indian oil; many clinical reports claim it to be superior. S. WALDBOTT

Johannes Gadamer, 1868–1928. ANON. *Pharm. J.* **120**, 384, 408(1928); *Schweiz. Apoth. Ztg.* **66**, 215–6(1928).—An obituary. S. WALDBOTT

The esterification of ethyl alcohol in citric acid solution. C. W. CORNWELL. *Pharm. J.* **120**, 391(1928).—In a lemon oil flavoring mixt. contg. 49.8% alc. (by vol.) and 25.5% citric acid, considerable esterification took place in 5 years; alc. became 38.9%, citric acid 12.46% (wt./vol.); sapon. showed 17.16% ester, indicating a quant. conversion of the disappeared alc. and acid; besides, the original quantities were recovered by sapon. and distn. The ester, $C_6H_5O_7Et_3$, does not hydrolyze nor distil to any appreciable extent when alc. and H_2O are distd. from a mixt. contg. it, nor can it be completely sepd. from alc. prepns. by means of petroleum ether. The free alc. in such a prepn. may be detd. by direct distn. if alkali and essential oils are absent; if both are present, by direct sepn. of the oil with the aid of brine, and distn. from the neutralized soln. S. WALDBOTT

Notes on three ointments. LENNOX TICE. *Pharm. J.* **120**, 391–2(1928).—To prep. *stainless I ointment, 5%*, dissolve finely powd. I, 1 part in warm oleic acid, 2 parts, add soft paraffin base, 17 parts and mix. In place of the stiff official *paraffin ointment*, T. suggests melting together beeswax, white or yellow, 1, hard paraffin 14, soft paraffin, white or yellow, 85 parts; stir until the mixt. congeals. A paraffin base should be used in Brit. Pharm. ointments in place of lard or suet, which in time turn rancid. In prepg. *mercurial ointment, 30%*, rub together Hg (30) with *hydrous wool fat* (20) and *oleic acid* (2) until the Hg is "killed," then add soft yellow paraffin (48 parts). The process is rapid and yields a "blue ointment" of good consistency. S. WALDBOTT

The adsorption value of surgical dressings. WALTER ZIMMERMANN. *Schweiz. Apoth. Ztg.* **66**, 13–8(1928); cf. *C. A.* **21**, 2050; **22**, 843.—In the place of the elaborate method of Demolis, a simple method of detg. the adsorbent qualities of a surgical dressing is proposed. Three nos. are detd.: (*a*) the *adsorption no.* (*AZ*), *i. e.*, the quantity of H_2O in g. adsorbed by 10 g. of the material, *e g.*, cotton; (*b*) the *sinking no.* (*SZ*), *i. e.*, the time (sec.) required for 10 g. of the material to sink in H_2O; (*c*) The *g.-min. no.* (*GMZ*) (by calcn.), *i. e.*, the no. of g. of H_2O adsorbed in 10 min. (600 sec.) by 10 g., of gauze, etc. For gauzes whose $SZ \gtreqless 600$ (which is the exception), $GMZ = (AZ/SZ) \times 600$. For gauzes whose $SZ \lesseqgtr 600$ (which is the rule), an arbitrary relation is given: $GMZ = AZ + (600 - SZ)$. In both cases when $SZ = 600$, $GMZ = AZ$. The 3 nos. were detd. for 65 samples of surgical dressings of all kinds; the results are tabulated. Av. normal values are for absorbent cotton: *AZ* 180–190, *SZ* 20–40, *GMZ* (calcd.) 720–750; for bandage linen ("Mull") *AZ* 60, *SZ* 10–20, *GMZ* 640. In exceptional cases, *e. g.*, the material being 15 yrs. old, *AZ* was 98, *SZ* 16,680, *GMZ* (calcd.) 3.5. S. WALDBOTT

Chemical valuation of arsenobenzenes. J. THOMANN. *Schweiz. Apoth. Ztg.* **66**, 37–40, 49–52(1928).—A critical survey of studies on the valuation of arsenobenzenes (*A*) based on their chem. and phys. properties (cf. *C. A.* **19**, 1756; **20**, 2561; **21**, 3104; **22**, 667). The German State keeps strict supervision of the quality of all *A* used in clini-

cal practice. The samples are centrally tested on the basis of a standard prepn. in regard to chem. compn., toxicity, curative value and clinical usefulness. As and S are detd., As by Kircher and Ruppert's method (*C. A.* **18**, 880); in neoarsphenamine the sulfoxyl group is also detd. T. detd. As by the method of Stollé and Fechtig (*C. A.* **17**, 2405) and found for Neoarsphenamine Höchst 19.5% As; Novarsenobenzene Billon 19.80%; Novarsol Burmann Genève 19.84% and Neo-Mesarca 914, Roche-Bâle 19.70%. The new Pharm. Helv. V may adopt besides neoarsphenamine Ag arsphenamine, Ag neoarsphenamine and Kolle's promising myoarsphenamine (*C. A.* **21**, 2032). It is hoped that a central testing lab. for this class of prepns. be established in Switzerland, and the Pharm. Helv. may simply give descriptions, soly., reaction of the soln. and a few qual. identity tests. A list of 13 references is appended. S. WALDBOTT

Pharmacy in Jugoslavia. VLADIMIR SIFFER. *Schweiz. Apoth. Ztg.* **66**, 94–6 (1928).—Informative. A new pharmacopeia is in prepn. to appear near the end of 1929. S. WALDBOTT

Products yielded by Solanaceae used as sensorial drugs. L. REUTTER DE ROSEMONT. *Schweiz. Apoth. Ztg.* **66**, 145–8(1928); cf. *C. A.* **19**, 2109.—A descriptive account is given of several drugs, mostly leaves which are smoked for their sensorial effects and are derived from species of *Hyoscyamus, Datura* and *Cestrum*. They are: *Pituri* (*petcherie*, etc.) made from the leaves of *Duboisia hopwoodii* F. v. Mull. by the natives of Central Australia; *tonga*, from *Datura sanguinea* (*Huacacachu, Yerba de Huaca, Bovachero*) used in Peru and Bolivia (Tschudi, 1838–42); *Datura stramonium* (*Jamestown weed*), together with *Arctostaphylos glauca* Ldl., *D. somniferum, D. meteloides* and *D. quercifolia* of Mexico, were smoked for their sedative and antiasthmatic effects by the N. American Indians; *Parqui*, from the leaves of *Cestrum parqui* L'Her. was used by the natives in Chile. In Siberia, a strong drink is prepd. by addg. leaves and crushed root of *Hyoscyamus niger* to fermenting beer. S. WALDBOTT

Phosphorated cod-liver oil. C. STICH. *Schweiz. Apoth. Ztg.* **66**, 169–71(1928).—Abstract of an address. The accepted standard for P content is 0.1 mg. per cc. Colorimetric detn. (*C. A.* **21**, 3856) showed in 18 samples from pharmacies an av. of 0.09 mg., in 8 com. samples 0.03 mg., in 4 com. samples 0.05 mg. per cc. S. WALDBOTT

Fenugreek. HUERRE. *L'évolution thérapeutique*, Dec., 1927; *Schweiz. Apoth. Ztg.* **66**, 182(1928); cf. *C. A.* **8**, 2601; **9**, 124; **13**, 2548, 2609, 3213; **20**, 2376; **21**, 2718.—Powd. fenugreek, rendered more palatable by removal of its oil, of a disagreeable odor, strongly stimulates general metabolism and aids assimilation. Its medicinal use is indicated in rickets, scrofula, anemia, etc. S. WALDBOTT

Table of injectable preparations, simple and compound formulas. ANON. *Schweiz. Apoth. Ztg.* **66**, 183–6(1928).—Ext. of a Report; cf. Lesure, *C. A.* **22**, 844. S. W.

Friedrich August Flückiger, 1828–1895. The centenary of his birth. SWISS APOTHECARIES UNION. *Schweiz. Apoth. Ztg.* **66**, 221–2(1928).—A memorial tribute, with frontispiece portrait of F. **His boyhood years.** AUGUSTA OESTERLE-FLÜCKIGER. *Ibid* 223–38.—With partly photostatic reprints of correspondence with his parents. **F. A. Flückiger, the historian of pharmacy.** J. A. HÄFLIGER. *Ibid* 239–46. **Memorial convocation at the University of Bern.** ALEXANDER TSCHIRCH. *Ibid* 262–5, 274–8 (1928).—Memorial address. S. WALDBOTT

The estimation of oil in extract of lemon. A discussion of the precipitation and polarimetric methods. The influence of temperature and aging upon the latter. C. V. NETZ. *J. Am. Pharm. Assoc.* **17**, 663–8(1928).—The U. S. P. X. tincture of lemon does not conform to the U. S. Dept. of Agr. Food Standards for ext. of lemon. Samples of lemon ext. of various strengths were made and assayed by the pptn. method. The method consists in adding H_2O to a known vol. of the ext. and centrifugalizing. A correction of 0.4% is added to the values found. N. finds that the best results are obtained when the entire length of the column of oil is measured rather than the vol. only. The correction factor of 0.4% is correct if the above procedure be followed. In the polarimetric method several factors must be considered. The α_D of lemon oils varies; EtOH is inactive but lemon oil dissolved in EtOH (5% sol.) loses about 8.5% of its activity. This must be allowed for if lemon exts. are to be assayed by the optical method. Since the rotation of pure lemon oil varies between 57° and 64° (generally between 59° and 62°) allowance must be made for this variable. The effect of temp. on the rotation of 5% exts. was studied. The variations in room temp. of 19–25° cause a max. error of but 0.07%. Aging of the exts. tends to cause an increase in rotation but the increase is not uniform in all exts.; so a factor cannot be calcd. from present knowledge. L. E. WARREN

The drug research unit and its value to the pharmaceutical industry. L. E. WARREN. *J. Am. Pharm. Assocn.* **17**, 737–44(1928).—An address. The Drug Research

Unit is a part of the Food, Drug and Insecticide Administration of the U. S. Department of Agriculture. Pharmaceutical manufacturers, schools of pharmacy and others are doing coöperative work with the unit in analytical methods for drugs. The drugs being studied are about 125 of those most used. L. E. WARREN

Cornin; a glucoside from Cornus florida L. EMERSON R. MILLER. Ala. Polytech. Inst. *J. Am. Pharm. Assocn.* **17,** 744–50(1928).—By the usual methods for obtaining glucosides, there was obtained from the root bark a white cryst. substance m. 182–3°, sol. in H_2O but sparingly sol. or insol. in the common org. solvents when cold, $[\alpha]_D$ —180.6° to —181.4°, neutral to litmus, extremely bitter; alkaloidal reactions are negative; N is absent; it reduces Bi salts in alk. soln. The action of emulsin indicates that cornin is a β-glucoside. Its carbohydrate nucleus contains *d*-glucose. It contains 1 Me group, and either an aldehyde group or one that is easily hydrolyzed with the formation of an aldehyde. L. E. WARREN

Notes on the assay methods of the U. S. Pharmacopeia X. T. F. PAPPE. U. S. Dept. Agriculture. *J. Am. Pharm. Assoc.* **17,** 844–8(1928).—Certain of the U. S. P. assays are criticized from the standpoints of inconsistency or faultiness, non-specificity for the material assayed, the use of indirect methods where direct methods might be employed, and methods which might be replaced or supplemented by other and better methods. Forty suggestions for improvement are made. L. E. WARREN

DEFACQZ, ED., AND WEITZ, R.: **L'officine de Dorvault, ou Répertoire général de pharmacie pratique.** Paris: Vigot Frères. 2014 pp.; F. 125. Reviewed in *Bull. soc. hyg. aliment.* **16,** 365(1928).

Therapeutic composition. CHARLES F. AMACKER. U. S. 1,686,062, Oct. 2. A compn. which may be locally applied as a bactericide is formed of salicylic acid 1 lb., a Hg deriv. of dibromofluorescein such as a 2% "mercurochrome" soln. 5 oz. and tincture of I 5 oz.

Synthetic drugs. SCHERING-KAHLBAUM A.-G. Brit. 285,001, Feb. 8, 1927. The CH_2O bisulfite compds. of 3-amino-4-auromercaptobenzene-1-sulfonic acid, *N*-α(β'-aminopyridyl)-4-amino-2-auromercaptobenzene-1-sulfonic acid and 3-amino-4-argentomercaptobenzene-1-sulfonic acid are made by treatment of their Na salts with Na formaldehyde bisulfite. 3-Amino-4-auromercaptobenzene-1-sulfonic acid is made by treating the diazo compd. of 2-nitroaniline-4-sulfonic acid with KCNS, reducing and then introducing Au into the thio group. *N*-α(β'-Aminopyridyl)-4-amino-2-auromercaptobenzene-1-sulfonic acid is made by reaction of the Na compd. of 4-amino-2-mercaptobenzene-1-sulfonic acid with α'-chloro-β'-nitropyridine, reduction and introduction of Au.

Coating for pills. S. HERMANN and PHARMACEUTISCHE WERKE NORGINE A.-G. Brit. 285,091, Feb. 12, 1927. Pills intended to pass through the stomach and to dissolve in the intestine are coated with stearic acid or similar aliphatic acid of low m. p. Other coating materials also are mentioned.

Aldehydes. I. G. FARBENIND. A.-G. Brit. 284,458, Jan. 19, 1927. Unsatd. aldehydes are prepd. by condensing an aldehyde having a CH_2 group in the 2-position to the keto group with an aldehyde of other character, in the presence of an alkali, an alc. and a minimum quantity of water. The products may be used as perfumes. Examples are given of the production of PhCH:CMeCHO, PhCH:CEtCHO, PhCH:C-(iso-Pr)CHO, *p*-$MeOC_6H_4CH$:CEtCHO, *p*-MeC_6H_4CH:CAmCHO, BuEtCHCH:CAmCHO, PrCH:CEtCH:CAmCHO, PhCH:CHCH:CEtCHO, PhCH:CHCH:CMeCHO, PhCH:CHCH:CAmCHO, PhCH:CMeCH:CMeCHO and PhCH:CMeCH:CEtCHO. Various other condensations also are referred to.

Alkaloids. A. BOEHRINGER (trading as C. H. Boehringer Sohn). Brit. 285,404, Feb. 15, 1927. Dihydromorphine is made by demethylating tetrahydrothebaine,

which may be produced by hydrogenating thebaine. The treatment may be effected in stages, in the last of which HBr may be used as the demethylating agent. Numerous details are given.

Tubes of radioactive material for therapeutic purposes. A. FISCHER. Brit. 285,467, Feb. 19, 1927. Structural features.

Hormones. SCHERING-KAHLBAUM A.-G. (formerly Chemische Fabrik auf Actien, vorm. E. Schering). Brit. 285,402, Feb. 15, 1927. Hormones such as those obtained from ovaries by extn. with MeOH and evapn. of the solvent are treated with alc. to remove albuminous substances, the alc. is evapd., the residue taken up with water and the suspension rendered alk. and extd. with ether. After evapn. of the ether, the residue is extd. with cold acetone or MeOH and the remaining lipoids are sapond. after removal of the solvent.

Tuberculin. I. G. FARBENIND. A.-G. Brit. 285,087, Feb. 11, 1927. Tuberculin prepns. are treated with precipitants such as dialyzed $Fe(OH)_3$ or Pb salts to remove albumins and their cleavage products and leave a soln. contg. active constituents which may then be sepd. by addn. of acetone, an alc. or of an alkaloid precipitant which is afterward eliminated. Various details are given.

Antirachitic preparations. W. MERCK, K. MERCK, L. MERCK, W. MERCK and F. MERCK (trading as the Firm of E. Merck). Brit. 285,083, Feb. 12, 1927. The unsaponifiable constituents of "low fungi" or of yeast-fat are esterified and the ester is treated with ultra-violet light, or ergosterol is treated with ultra-violet light and the activated product is then esterified. When the acetic ester of ergosterol is treated, there results a yellowish resinous substance sol. in alc. and oils and various other solvents.

Extracts from glands of sharks, etc. A. EHRENREICH. Brit. 284,668, Feb. 3, 1927. Products "of the nature of enzymes," which may be used for treating skins before tanning, ungumming silk, as medicines for raising blood pressure or causing contraction of organs and for anaesthesia are prepd. by degreasing and extg. glands such as those under the esophagus, the first intestinal gland, genital glands and other glands. Numerous details are given.

Bile acid salts of cephaeline alkyl ethers. ERNST ROTHLIN and FRITZ MÜLLER (to Chemical Works formerly Sandoz). U. S. 1,686,930, Oct. 9. See Brit. 283,553 (*C. A.* 22, 4131).

Barbituric acid derivatives. I. G. FARBENIND. A.-G. Brit. 285,598, Dec. 7, 1926. Barbituric acids contg. alkinyl groups are prepd. according to the usual esterification methods for the production of barbituric acids, but using alkinyl esters for alkyl esters. Examples are given of the production of isopropylpropargylbarbituric acid, isopropylmethylpropargylbarbituric acid and propargyldiethylmethinebarbituric acid. The products are *soporifics*. Isopropenylpropargyl bromide is made by treating isopropenylacetylene with Mg Et bromide, reacting on the product with CH_2O to form isopropenylpropargyl alc. and then forming the bromide by treatment with PBr_3.

Ichthyol substitutes. N. G. SHCHEKOLDIN. Russ. 4,557, Sept. 15, 1924. Ichthyol substitutes are obtained by distg. bituminous shale with S, pyrite or the mined substance itself with exclusion of air.

Medicinal baths. C. DRANGSHOLT. Brit. 285,356, Feb. 12, 1927. Alkali humates such as those of Na and Li are used in prepg. medicinal baths. Humic acid is obtained from peat by crushing, disintegrating with water and heating to 100°, or by freezing followed by heating, followed by extn. with alkali and pptn. with acid. Other details also are given.

Surgical suturing and bandaging material. MARIA, COUNTESS VON LINDEN. Brit. 285,464, Feb. 17, 1927. Material for surgical purposes is rendered sterile and antiseptic by impregnation with Na_2SO_4, Cu glyceride, Cu sulfide, cuprosol or cuprosol and methylene blue. Cumene may also be used for treating material such as catgut.

Synthetic perfumes. J. D. RIEDEL A.-G. (to F. Boedecker). Brit. 284,199, Jan. 24, 1927. *m*- and *p*-Ethylprotocatechuic aldehydes are made by treating safrole or camphor oil with alc. alkalies as described in Can. 275,947 (cf. *C. A.* 22, 1597) but ethylating the product instead of methylating it. Sepn. is effected as the propenyl pyrocatechol ether contg. the alkyl radical in the *p*-position to the propenyl group is more difficultly sol. than the corresponding *m*-compds.; also the alkali salts and the acidyl compds. of the propenyl pyrocatechol ether ethylated in the *m*-position are more difficultly sol. than the *p*-compds. and the *m*-ethylprotocatechuic aldehyde dissolves more easily in alkali carbonates than the *p*-compd. Examples are given.

Cosmetics containing dyed starch and powdered talc or similar substances. A. O. MORRIS. Brit. 284,830, Dec. 23, 1926. The starch used may be dyed by spraying with an aniline dye soln.

Disinfectants. PAUL JAMOTTE. Fr. 635,683, June 9, 1927. See Brit. 272,900 (*C. A.* 22, 1833).

Cleansing nicotine vapors. ROBERT G. MEWBORNE. U. S. 1,684,740, Sept. 18. A stream of vapors contg. nicotine and impurities is treated with an alkali soln. such as NaOH and the temp. is maintained (suitably at about 100° or higher) to prevent condensation of the nicotine and the latter is subsequently recovered from the vapors.

Accelerated fermentation of cigaret tobacco. M. D. KOLENEVA. Russ. 4168, Sept. 15, 1924. Leaf and crumbled tobacco with a moisture of about 28% is gradually heated up to 60–80° for 12 hrs. in closed chambers and left for another 12 hrs. at the same temp.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

Manufacture of synthetic nitric acid from nitrogen oxides under pressure. V. I. MALYAREVSKII AND V. V. PAPKOV. *J. Chem. Ind.* (*Moscow*) 5, 682–9(1928); cf. Malyarevskii, *C. A.* 20, 3333; 21, 3712; 22, 3266.—Under normal factory conditions NH_3 reacts with air in the zone of contact, conforming to the reaction $4NH_3 + 5O_2 = 4NO + 6H_2O$, the yield of NO being about 90%. NO is subsequently transformed by the air into NO_2 or N_2O_4, which may be converted into HNO_3 by absorption in water: $3N_2O_4 + 2H_2O = 4HNO_3 + 2NO$; $3NO + 3NO_2 + H_2O = 2HNO_3 + 4NO$. There is a tendency to improve the existing absorption systems either by effecting a contraction of the size of the installation per unit of production (attained by increasing the intensity of contact between the gas and the liquid), or by the use of artificial cooling (cf. Toniolo, *C. A.* 13, 892). To bring about these improvements the only factors which have hitherto been considered are the temp. of oxidation, the temp. of absorption and the intensity of contact of the gas with the liquid; the concn. of NO and O_2 in the nitrogeneous gas, a factor of far greater importance, has been ignored. This concn. may be increased either by using O_2 instead of air in the oxidation of NH_3, or by operating under pressure. While the use of O_2 can only be considered in those localities where this gas is inexpensive, the use of pressure would be advantageous everywhere. When operating under pressure, the concn. of NO and O_2 in the gas increases and brings about the increase of the speed of NO oxidation almost in proportion to the square of the increase of pressure; at the same time the speed of NO_2 absorption also increases. When operating under pressure any desired degree of contact of the gas with the liquid can be attained and, by utilizing the expansion energy of the spent gas, cold may be produced, by means of which the speeds of NO oxidation and of N_2O_4 absorption may be still further increased. Finally, the use of pressure would permit the obtaining, as a final product, 65–67% HNO_3, instead of the 50–52% acid obtained at present. A drawing and a description of construction of a projected installation (plant) for effecting the absorption under pressure are presented. It is essential to be able to remove rapidly and completely the heats of NO oxidation and of absorption of N oxides in the course of the circulation of the gas through the system. The N oxides of the temp. of 150° or over, coming out after the contact, are led into a compressor where they are compressed to 10 or more atms. at 250–300°, after which they enter a water-cooled cooler where they cool off to below 50°; from there they go through a series of externally cooled tubular absorber-refrigerators where their oxidation and their absorption take place by the absorbing liquid. For the latter it is best to use the reaction water from the nitrogenous gas, but ordinary water could also be used. All the parts of the installation must be made of acid-proof metal (ferrosilicon or Cr steel). A detailed calculation of the fundamental elements of the installation is appended. As the construction of the tubular absorber-refrigerators permits the max. development of cooled surface at a min. of reaction space, a very compact app. results. The total capacity (vol.) of an installation working under a pressure of 10 atms. and intended to convert N oxides into HNO_3 with a 95% yield should only be equal to 2.5 cu. m. per ton NH_3 in 24 hrs. An additional absorber to obtain a mixt. of nitrite-nitrate by alk. absorption can be attached at the end of the system, *viz.*, after the refrigerators; in that case the efficiency of the plant could be increased and the necessary vol. (size) per 1 ton per 24 hrs. should not be greater than 1.5 cu. m. The expansion energy of the spent gas released from the compressed system may either be regenerated as such (pneumatic motor), or utilized to obtain the cold needed for cooling the end of the system; the purpose of the cooling is not only to accelerate NO oxidation and absorption of N oxides, but also to decrease the moisture content in the used up gas. The latter has the compn.: N 98.28, O_2

1.22 and NO 0.50% and can be utilized, after a slight purification, in the *manuf. of Ca cyanamide, synthetic NH_3*, etc., Fauser (cf. *C. A.* **22**, 3738) arrived almost simultaneously at *the same views concerning the use of pressure in the manufacture of HNO_3*. While Fauser and the authors agree on most points, there are fundamental differences concerning the following details: (1) Fauser conducts not only the absorption of N gases, but also the contact reaction under pressure; yet this is not advisable, as the greater the pressure the less efficient the NH_3 oxidation. (2) The absorber construction plans of the authors have the advantage over Fauser's column system app. of avoiding parts of large diam. (3) The authors prefer to use the expansion energy of the spent gas for refrigeration of the tail-end of the absorption system, their fundamental purpose being to effect the max. of intensification of the process and the max. diminution of reaction vols. BERNARD NELSON

Manufacture of sulfuric acid from gypsum. JAROSLAV MILBAUER. *Chemický obzor* **1**, 317–8; *Chem. Zentr.* **1927**, II, 968—Discussion of the principal processes. G. SCHWOCH.

Manufacture of carbon dioxide. H. E. HOWE. *Ind. Eng. Chem.* **20**, 1091–4 (1928).—A brief illus. description of the Dry Ice Corp. at Elizabeth, N. J. There are 3 units, each consisting of a coke-fired boiler, 2 scrubbing towers, 2 absorbing towers, a heat interchanger, a lye boiler and cooling coils. The compressor room works on gas from a common header of gas from a holder. A flow chart for the manuf. of solid CO_2 is shown. W. H. BOYNTON

Sulfur, pyrite and sulfuric acid. ARTHUR E. WELLS. *Mineral Ind.* **36**, 542–52 (1927).—A review, with statistics of production and trade. A. B.

Synthetic ammonia costs in America. R. S. TOUR. *Chem. and Met. Eng.* **35**, 89–91, 162–4(1928).—Tabulations in very great detail show the production cost from water gas to be 6.33 cents and from electrolytic H_2 as 6.75 cents per lb. of NH_3. E. M. SYMMES

Note on the formation of ammonia from active nitrogen and active hydrogen. BERNARD LEWIS. *J. Am. Chem. Soc.* **50**, 2427(1928); cf. *C. A.* **22**, 668.—Koenig and Elöd (*Z. Elektrochem.* **21**, 285) obtained negative results in the synthesis of NH_3 from H_2 and N_2 after each had been activated separately in the elec. discharge, contrary to the results of L. This discrepancy is explained by the recombination of at. H before reaching the mixing point, a condition favored by the higher gas pressures used in the expts. of K. and L. H. R. MOORE

Considerations on the choice of a process for the synthesis of ammonia. CAMILLE MATIGNON. *Chimie et industrie* **20**, 365–7(1928).—A brief discussion showing the advantages of high-pressure (Claude) over low-pressure (Haber) processes. A. PAPINEAU-COUTURE

The consumption of raw materials in the ammonia-soda process. II. JULIUS KIRCHNER. Kispest, Ungarn. *Chem.-Ztg.* **51**, 746–8(1928); cf. *C. A.* **21**, 2760; **22**, 482.—In the modern NH_3-soda plant, 0.3 to 0.4 kg. $(NH_4)_2SO_4$ are lost for every 100 kg. of product. This loss occurs in the exit gases, the foots, leaks and from the furnaces. The total lime consumption in the production of 100 kg. of 98.8% Na_2CO_3 is 58.35 kg., whereas the theoretical is 52.2 kg. The theoretical and practical consumption of coal for the whole process is also discussed. J. H. PERRY

The action of alkalies and alkaline salts on fuller's earth. OTTO ECKART. *Ölmarkt* **9**, 129–30; *Chem. Zentr.* **1927**, II, 1414.—It is impossible to neutralize activated, and therefore weakly acid, fuller's earth, with alkalies without a deteriorating effect. This is due to the pptn. of Fe and Al salts, the formation of silicates, and (with strong alkalies) the soln. of the silicates formed. J. S. REICHERT

The Blättner process for the manufacture of caustic soda from sodium carbonate. HIRCHBERG. *Chem.-Ztg.* **51**, 765(1927).—The process described is a modification of the Loewig process (Ger. pat. 203,271 (1923)). A part of the crude Na_2CO_3 is heated with Fe_2O_3. CO_2 is evolved and the residue is leached with H_2O to give a NaOH soln. The CO_2 is passed through a soln. of the crude Na_2CO_3 to ppt. $NaHCO_3$, which upon heating gives pure Na_2CO_3. The CO_2 is compressed and sold. The Loewig process required 300 parts of Fe_2O_3 to 100 parts of crude Na_2CO_3, while this modified process requires only about 150 parts of Fe_2O_3. The process is most efficient as regards fuel, labor and time. The problem of a suitable furnace for the metallic oxide treatment is not considered difficult. J. H. PERRY

Potash. J. W. TURRENTINE. *Mineral Ind.* **36**, 477–90(1927).—The industry in the U. S. and foreign countries is reviewed. A. B.

The lime-burning process. GUSTAV F. HÜTTIG AND MATHIAS LEWINTER. *Z.*

angew. Chem. **41,** 1034–43(1928).—During the greater part of the CO_2 evolution there are 3 phases: completely unchanged $CaCO_3$, a phase of variable compn. and amorphous to cryst. CaO which apparently contains variable but small quantities of CO_2 in its structure. According to the phase rule these 3 phases cannot co-exist under the given conditions. The unstable phase is the unchanged $CaCO_3$ with its very slow decompn. velocity at the ruling CO_2 pressures. The 2 other phases and the CO_2 evolved at const. pressure are components of a system of equil. in which the phase comprising unaltered $CaCO_3$ does not play the role of a component. E. M. Symmes

Replacing lime by iron sesquioxide in the manufacture of sodium chromate. F. F. Volf and L. I. Popov. Northern Chem. Trust. *J. Chem. Ind. (Moscow)* **5,** 618–25 (1928).—In the manuf. of Na_2CrO_4 according to the reaction $4FeCr_2O_4$ (chromite) + $8Na_2CO_3 + 7O_2 = 8Na_2CrO_4 + 2Fe_2O_3 + 8CO_2$, CaO is used to prevent fusion of the mass at the high temp. (1100–1200°). The mass must remain porous to insure access of air to all particles of the Cr ore to be oxidized. The use of CaO, which is not supposed to take part in the reaction, is objectionable because it gives a lime product which cannot be utilized and also because it causes a loss of some Cr as $CaCrO_4$, which cannot be extd. by leaching with H_2O (*C. A.* **20,** 2564). Moreover, some CaO dissolves with the Na_2CrO_4 and contaminates the latter. The possibility of replacing CaO by Fe_2O_3 was suggested by (1) a by-product consisting of Fe_2O_3 which could be briquetted and used as an Fe ore or in Fe oxide paints; (2) Na ferrite, possibly formed in the reaction, is a very strong alkali which may contribute substantially to the successful decompn. of chromite; (3) in the oxidation of chromite at the high temp. Fe_2O_3 could be expected to act catalytically as an O carrier. Such use of Fe_2O_3 is shown in German patents 82,980 (Oct. 10, 1894) and 166,767 (Sep. 11, 1904) and *C. A.* **21,** 3428. In all, 56 expts. were run. Heating took place in a Hereaus elec. furnace, the temps. were measured by a Pt-PtRh thermocouple, the chem. control consisting in detg. the percent of decompn. of chromite and Cr extn. Thirteen tables show the effect of the degree of purity of Fe_2O_3, time of ignition, fineness of materials, amt. of Na_2CO_3 used, etc. When employing CaO the latter is commonly used in amts. equal to the wt. of chromite and Na_2CO_3 in amts. required theoretically to form Na_2CrO_4. The ore is ground to pass a No. 120 screen, the temp. is 1100° and time of calcination 1.5 hrs. If CaO is merely replaced by Fe_2O_3, all other conditions remaining the same, the conversion is lowered sometimes more than 20%. When using Fe_2O_3 much better yields are obtained by increasing the Na_2CO_3, grinding more finely and increasing the time of calcining, because any SiO_2 present must be satd. When using CaO part of the latter is consumed in this way, whereas with Fe_2O_3 the Na_2CO_3 is consumed and its quantity must be increased but not above 1.3 times that required theoretically to form Na_2CrO_4. Otherwise the mass might fuse at 1100° and decrease the oxidation greatly. With this 1.3 times increase of Na_2CO_3, all other conditions remaining the same, the per cent Cr extn. is equal to that by the CaO method, or 93.2%, if pure Fe_2O_3 is used. With hematite or calcined pyrite the Cr extn. is 89.2 and 83.2, resp. Pyrite cinders give low Cr oxidation because it does not prevent the mass fusing at 1100° or even lower when a 20% Na_2CO_3 excess is used. Below 1000° the mass can be kept porous even with 1.5 times the theoretical excess of Na_2CO_3, with a Cr extn. of 88.3%. Even when using only a 30% Na_2CO_3 excess excellent yields can be obtained if the materials are put through a No. 200 screen; with pure Fe_2O_3 95.9% after 1.5 hrs. and 97.5% after 4.5 hrs., with red hematite 92.1% after 1.5 hrs. and 94.4% after 4.5 hrs., with calcined pyrite and a lower temp. 87.4% after 1.5 hrs. and 94.1% after 4.5 hrs. A calcn. shows that the cost of Na_2CrO_4 by the Fe_2O_3 process is considerably lower than that by the CaO method. In the new process there are 2 stages, calcination of chromite with one-half the Na_2CO_3 required theoretically for decompn., and calcination with additional Na_2CO_3 of the first product after subjecting it to a water treatment to ext. the Na_2CrO_4 formed. Bernard Nelson

Sodium salts. Alan G. Wikoff. *Mineral Ind.* **36,** 532–41(1927).—Nitrate, fixed nitrogen, salt, carbonate and sulfate are discussed, including production and technology. A. B.

Purification of technical ammonium bicarbonate. W. Gludd and W. Riese. *Ber. Ges. Kohlentechn.* (Dortmund-Ewing) **2,** 259–67; *Chem. Zentr.* **1927,** II, 2250.—NH_4HCO_3 obtained from the mining industry is not pure white, but is yellowish brown to gray on account of inorg. and org. impurities. An *app. and technic* are described, whereby the product is vaporized in the presence of active C at approx. 80°, the condensate being pure white. C. C. Davis

Barium carbonate. Thomas O. Marvin, *et al.* *U. S. Tariff Commission Rept.* **1928,** 18 pp.—Data are given on the uses, raw materials, methods of production, domes-

tic production and consumption, foreign production, imports, prices and costs of production in the U. S. and in Germany for barium carbonate. PAUL J. CULHANE

Purification of crude barium chloride by sodium chloride. I. E. ADADUROV AND K. I. BRODOVICH. Kharkov State Inst. of Applied Chem. *J. Chem. Ind.* (*Moscow*) **5**, 640–2(1928); cf. *C. A.* **22**, 3740.—The difference of soly. of $BaCl_2$ and $PbCl_2$ in HCl has been utilized for the purification of the former. As, however, the cost of HCl is high, an investigation was made of the soly. of $BaCl_2$ in aq. NaCl solns. of various concns. and various temps. A soly. table of $BaCl_2.2H_2O$ in 5, 15, 25 and 30% solns. of NaCl at 16°, 25°, 35°, 40°, 60°, 80° and 100° is given. The solubilities of $BaCl_2.2H_2O$ in NaCl solns. were compared with those in HCl of the same concns. and it was found that, when dealing with 25–35% solns. of either NaCl or HCl, the former are several times as great. It is remarkable that the soly. of $BaCl_2.2H_2O$ in NaCl solns. drops to a minimum at 35°; the reason for this phenomenon may be looked for in the dissociation of NaCl soln. at 35° and the consequent increase of Cl ions. A table of soly. of $PbCl_2$ at various temps. in various concns. of NaCl soln. is also given. It shows that the soly. of $PbCl_2$ increases with the increase of NaCl concns.; the reason must be attributed to the formation of the double salt $PbCl_2.2NaCl$. The formation of a double salt ($PbCl_2$.-2HCl) must also be assumed in the case of solns. of $PbCl_2$ in HCl. The solubilities of $PbCl_2$ in NaCl solns. of various concns. are nearly the same as those in HCl of the same concns. Thus the use of NaCl solns. for purification of $BaCl_2$ is perfectly justifiable. However, the main impurity of tech. $BaCl_2$ is PbS; the latter is converted into $PbCl_2$ when using concd. HCl as a solvent, but does not dissolve on being treated with NaCl solns. To purify technical $BaCl_2$ a 31° Bé. soln. of the latter was made and PbS was removed either by filtration *in vacuo* or by acidifying at 100° with HCl; to this hot soln. NaCl was added in the quantity of 250–270 g. per l., the soln. was cooled to 35–40° and the $BaCl_2$ which pptd. was filtered *in vacuo.* The ppt. was 99% $BaCl_2$ and was quite white; it represented 90% by weight of the total quantity of $BaCl_2$ originally contained in the soln. The filtrate contained 58–65 g. $BaCl_2$ and 258–265 g. NaCl, of which the former salt may be pptd. by H_2SO_4 and can find utilization as *blanc fixe;* the remaining soln. may be used in the next operation as pure NaCl soln. B. N.

Borax. PAUL D. V. MANNING. *Mineral Ind.* **36**, 64–8(1927).—Uses and sources of borax are discussed and statistics given. A. B.

The influence of the changed market situation of nitrogenous materials upon the production of Chile saltpeter. JAN HAMPL. *Chemický obzor* **3**, 169–72(1928).—The developmental possibilities of the Chile saltpeter industry are discussed on the ground of statistics of production and consumption of nitrogenous materials, with consideration of the new, more economic methods of recovering Chile saltpeter, especially the Guggenheim method. JAROSLAV KUČERA

Chile saltpeter or synthetic sodium nitrate. H. EDDELBÜTTEL. *Z. angew. Chem.* **41**, 309–14(1928).—A discussion of whether the I content of Chile saltpeter is such as to displace the use of other products in its favor. It is evident that as long as only possibilities for certain advantages of the Chile saltpeter exist and no definite proofs are at hand, the German saltpeter is to be preferred. E. F. SNYDER

The explosive properties of solid hypochlorite. JOSEF WEICHHERZ. *Chem.-Ztg.* **52**, 729–30(1928).—$Ca(ClO)_2$ was supplied in sheet lead containers for disinfection purposes. While being transferred to small boxes contaminated by an alc. soln. of beech tar soap the contents deflagrated. The original boxes remained intact. Closed, original containers often show as much as a 10% internal pressure at 25°, due to O_2 evolution. At 100° to 112° $Ca(ClO)_2$ decomposes rapidly and often violently. When mixed with dry org. substances there is no reaction at ordinary temp. but ignition below 100°. Dry mixts. of $Ca(ClO)_2$ and beech tar soap did not ignite, but when moist there was oxidation, chlorination and rise of temp. to the ignition point. $Ca(ClO)_2$ is not dangerous for disinfection purposes. Deflagration occurs only on strong heating or when mixed with combustible substances. E. M. SYMMES

Accidents in the production of lead bromate. WITT. *Zentr. Gewerbehygiene Unfallverhüt.* **14**, 342–3; *Chem. Zentr.* **1927**, II, 2384.—Two accidents which occurred in the prepn. of $Pb(BrO_3)_2$ from $Pb(OAc)_2$ and $KBrO_3$ are cause for warning that when $Pb(BrO_3)_2$ is made in this way the dangerously explosive diacetatoplumbobromate is formed. $Pb(BrO_3)_2$ prepd. from Pb salts and HBr and KBr or from $PbCO_3$ and HBr is much more safely handled. C. C. DAVIS

Evaluation of silicon carbide and synthetic corundum. H. DANNEEL. *Chem. Fabr.* **1928**, 164–7.—The manuf., properties and various grades of the carbide and of fused Al_2O_3 (artificial corundum) are described. Chem. examn. in both cases is difficult,

and not necessarily conclusive; reliance must be placed on the phys. properties and on microscopical examn. B. C. A.

Iron carbonyl and carbonyl iron. A. MITTASCH. *Z. angew. Chem.* **41,** 827–33 (1928).—Fe pentacarbonyl is produced on the large scale by circulating CO under pressure over sponge Fe at 150–200° and cooling the gases evolved. It has d_4^{20} 1.453, a surface tension of 22 dynes per cm. and a viscosity of 0.0075 c. g. s. unit at 20°. Its heat of formation (liquid) is 54.2 kg.-cal., latent heat of fusion 3.25 kg.-cal. per mol., and heat of combustion 384.5 kg.-cal. per mol. In alk. soln. it behaves as a powerful reducing and dechlorinating agent for org. compds. In pentane soln. it combines with Br, forming a yellow unstable compd. which rapidly decomposes with the evolution of CO and the formation of the reddish brown compd., $Fe(CO)_4Br_2$. Iron pentacarbonyl decomposes at 250° in a hollow vessel heated by radiation, yielding a finely divided Fe contg. about 1% C. If this is melted in a vacuum high-frequency furnace together with the requisite quantity of pure FeO, obtained by combustion of the carbonyl, an exceedingly pure Fe of high permeability, low hysteresis and small wattage loss is obtained. B. C. A.

Dyeworks sulfites from waste. E. T. ELLIS. *Dyer, Calico Printer* **60,** 60–1, 73 (1928).—The manuf. of $(NH_4)_2SO_3$, $CaSO_3$, $Ca(HSO_3)_2$, $CaMg(SO_3)_2$, K_2SO_3, $KHSO_3$, Na_2SO_3 and $NaHSO_3$ from by-product wastes is discussed. RUBY K. WORNER

Asbestos. OLIVER BOWLES. *Mineral Ind.* **36,** 40–8(1927).—A review of the industry, including sources of asbestos, outputs, properties and uses. A. B.

Fluorspar. HUBERT W. DAVIS. *Mineral Ind.* **36,** 206–10(1927).—An account of consumption, output and trade. A. B.

Fuller's earth. HERMAN GUNTER. *Mineral Ind.* **36,** 211–2(1927).—Statistics of production and trade are given. A. B.

Gypsum. W. M. MYERS. *Mineral Ind.* **36,** 278–83(1927).—Statistics are given, together with discussion of technology and mine and mill developments. A. B.

Magnesite. HUGH M. HENTON. *Mineral Ind.* **36,** 373–82(1927).—The magnesite industry, *Mg* and *alloys* are discussed with statistics and a bibliography. A. B.

Mica. ANON. *Mineral Ind.* **36,** 396–400(1927).—A review of the industry. A. B.

Monazite. ANON. *Mineral Ind.* **36,** 405–6(1927).—Statistics of production and imports are given. A. B.

Talc and soapstone. PETER A. MCGURK. *Mineral Ind.* **36,** 553–60(1927).—Production and research on properties and uses are discussed. A. B.

Phosphate rock. K. D. JACOB. *Mineral Ind.* **36,** 446–60(1927).—A discussion of production and technology, with statistics and a bibliography. A. B.

Arsenic. F. Y. ROBERTSON. *Mineral Ind.* **36,** 34–9(1927).—Production and uses are discussed. A. B.

Barium and strontium. CHARLES HARDY. *Mineral Ind.* **36,** 56–60(1927).—A statistical review of the industry. A. B.

Selenium and tellurium. S. SKOWRONSKI. *Mineral Ind.* **36,** 525–6(1927).—New uses are discussed and a bibliography is given. A. B.

Titanium and zirconium. J. W. MARDEN. *Mineral Ind.* **36,** 584–90(1927).—Sources and technical developments are discussed. A section on hafnium is included. A. B.

Extraction of bromine by solvent. II. B. G. PANTELEIMONOV. *J. Chem. Ind. (Moscow)* **5,** 484–9(1928); cf. *C. A.* **22,** 3741.—Kerosene is usually removed incompletely from $Br\text{-}H_2O$ after extn. A certain amt. of it is lost as an emulsion with H_2O, involving not only loss of kerosene but also the Br dissolved in it. With Br solns. in pure H_2O the loss of kerosene from emulsion formation is 1 to 2% after each extn., and the loss of Br caused by it is 14.1 to 26.1% after 15 extns. With natural Br waters, such as lake waters contg. much salt in soln., emulsions are apt to form which do not sep. a kerosene layer on standing. An elec. current would break these emulsions, but filtration through porous substances having great adsorptive power, such as sponges or clays, is simpler. Sponges become soaked with kerosene and need pressing only to recover it with a kerosene loss of not more than 0.5% per extn. Br dissolved in kerosene becomes converted into HBr during adsorption by a sponge, due to surface tension, so that the recovered kerosene contains no dissolved Br and can be used directly for a new dissolving operation without previous treatment with alkali, whereas the aq. soln. sepd. from the emulsion contains all its dissolved Br as HBr. The latter is formed in the aq. soln. during extn. of Br by kerosene. With decrease of concn. of Br in the water from gradual extn. the amt. of HBr formed increases.

The longer kerosene is agitated with the water the more Br is converted to HBr. Br can be set free again by Cl. A detailed calcn. shows the low cost of Br production by this method and 11 tables give various data. BERNARD NELSON

Bromine and iodine. ANON. *Mineral Ind.* **36**, 69–70(1927).—Production and sources are discussed. A. B.

Iodine and gelatiginous substances from Laminaria. B. PENTEGOV, R. NYANKOVSKII AND I. PLAKSIN. *Lab. allgem. physikal tech. chem. Staatl. Univ. fernen Ostens* **1927**, 121–5; *Chem. Zentr.* **1927**, II, 2405.—Analyses showed that *Laminaria japonica* contains 0.43–0.54% I and *Laminaria bullata* 0.38–0.41% I. The practical yield of I is up to 0.18% and of dry alginic acid up to 16.2%. C. C. DAVIS

New method for the immediate production of hydrogen under pressure in the laboratory or in the field in the absence of a supply of water. FERNAND LEFEBVRE. *Chimie et industrie* **20**, 231–2(1928).—H under pressure is produced by the action of ferro-Si on NaOH according to the reaction $Si + 2NaOH + H_2O = Na_2SiO_3 + 2H_2 +$ 170 cal. The reaction is carried out in a pressure bottle which can be easily charged with the chemicals and furnishes the gas under a pressure of 50 atm. or more. The increase in pressure caused by the confining of the gas would tend to limit the reaction but this is offset by the increase in temp. which rises to about 180° and permits the reaction to proceed to completion. The construction and operation of the app. are described. A. PAPINEAU-COUTURE

Gas manufacture for the filling of balloons. II. JAROSLAV MILBAUER. *Chemický obzor* **2**, 107–15; *Chem. Zentr.* **1927**, II, 968.—M. describes the manuf. of H_2 and He suitable for the filling of balloons and airships. H_2 is obtained by action of metals on acids or alkalies, also from H_2O or hydrocarbons. He is obtained from natural gas exclusively. The different methods of H_2 production and the processes of filling, purifying and transporting, as they are in use in different countries, especially for military purposes, are described. The production, transportation and recovery of He are discussed. G. SCHWOCH

The separation of krypton and xenon from atmospheric air. ADOLPHE LEPAPE. *Compt. rend.* **187**, 231–4(1928).—The methods used hitherto to sep. Kr and Xe from air give very low yields (2–6%). Both gases will distil O_2 in spite of their low vapor pressure. L. puts a tube of coconut charcoal or silica gel in the neck of a Dewar flask from which O_2 is distg. The gas adsorbed in the tube is freed from CO_2, O_2 and N_2. Yields of 86 to 100% of Kr and Xe were obtained with either the charcoal or the gel. G. C.

The commercial preparation of oxygen from lime and chlorine. O. R. SWEENEY AND A. W. RALSTON. Ia. State Col., Ames. *Proc. Iowa Acad. Sci.* **34**, 215(1927).—The reaction of Cl on a suspension of lime in the presence of suitable catalysts, such as Ni, Co and Fe salts, has been studied. It was found that the optimum temp. is 94°; that the greatest unit efficiency of the catalyst, Ni nitrate, is obtained at a concn. of 0.02 g. per 100 cc.; that the rate of generation of O_2 is almost directly proportional to the rate of flow of the Cl and that Ni and Co salts are distinctly superior to all other catalysts which were used. In addn. it has been found that the catalyst is not easily poisoned, and may be used throughout a no. of runs. An app. has been designed which is capable of producing pure O_2 from lime and Cl and which is capable of recovering the catalyst for further use. By the process Cl, now a drug on the market, is converted into $CaCl_2$ and yields O_2, both of which are in demand. W. G. G.

Preparation of carbon by decomposition of carbon monoxide. F. v. WANGENHEIM. *Brennstoff-Chem.* **8**, 385–8(1927).—Expts. are described wherein C is prepd. by the reaction $2CO \longrightarrow C + CO_2$ using metallic Fe as catalyst, the temp. being 450°. Kahlbaum's pure Fe is volatilized as $FeCl_3$ in a current of Cl at 200–250°. The $FeCl_3$ is dissolved and pptd. as $Fe(OH)_3$ with caustic alkali. The ppt. is washed, redissolved and repptd. with NH_4OH. The purified hydrated oxide is put into porcelain boats which are placed in a reaction tube heated to 450° electrically. The C which pptd. on the catalyst, reduced by CO, could with pure CO amount to 74% before the catalyst became inactive. When a mixt. of $CO:H_2 = 1:1$ was used the C could be increased to 96.2%. Attempts to free the C so prepd. from Fe by volatilization of the latter in Cl were only partially successful. Traces of Fe always remained in the C. This may have been due to the presence of small amts. of Fe carbides. J. D. DAVIS

Methods for the preparation of activated carbon. ADOLF BRÄUER AND JOSEF REITSTÖTTER. *Z. angew. Chem.* **41**, 536–9(1928).—The production of activated C is traced through its period of development by reference to specific German patents illustrating the principles and methods employed. These are classified as follows: (1) carbonization of wood (22 patents); (2) treatment of peat and coal (22 patents); (3) carbonization of miscellaneous raw materials (20 patents); (4) various methods of prepn.

and regeneration (20 patents); (5) filtration carbons (21 patents); (6) app. patents (13 patents). W. C. Ebaugh

Activated silica gel (Sulfosil). B. Tuichinin and V. Tokmanov. *Neftyanoye Khozyaistvo.* **12,** 414–5(1927); *Chem. Zentr.* **1927,** II, 1524–5.—Preliminary communication. Silica gel satd. with H_2SO_4 or fuming H_2SO_4 is suggested for treating mineral oils and similar products, to replace the old method in which oils are treated with concd. H_2SO_4 or fuming H_2SO_4 and adsorbers. This gel (Sulfosil) is prepd. by drying it at 300° and mixing it gradually when still hot with H_2SO_4 heated to 200° to 250° or fuming acid at 50°. The silica gel is able to adsorb without being changed externally 2.4 parts of H_2SO_4 and 0.6 parts of SO_3. Gels were used mostly with 0.2 parts of SO_3. Sulfosil is hygroscopic and looses its activity when left in the air. A. A. Boehtlingk

Graphite. A. Dubosc. *Caoutchouc and gutta-percha* **25,** 14117–8(1928).—Data on the d., volatile matter, C and ash of numerous graphites are compiled. Cf *C. A.* **22,** 1217, 2641. C. C. Davis

Graphite. Benjamin L. Miller. *Mineral Ind.* **36,** 269–77(1927).—A statistical discussion of world sources and production. A. B.

The knowledge and literature of graphite. Ed. Donath. *Chem.-Ztg.* **52,** 589–90, 610–11, 650(1928).—A review of the graphite literature and of the work of D. and of A. Lang on graphite. The prepn. of pure graphite free of all accessory elements such as N, S, Fe and especially H is difficult. H detd. after heating the graphite to 800–830° is considered as accessory to the graphite proper, while the S is associated with the Fe rather than with the graphite itself; N can be detd. by the Kjeldahl method, with a mixt. of 30 cc. H_2SO_4, 18 g. K_2SO_4, 1 g. CuO and 1 g. HgO; the oxidation takes 3–7 days. In 28 diff. graphites analyzed the H content varied from 0.05 to 0.13%; total S minus ash S was 0.01–5.02%, N 0.021–0.182%. Acheson graphite, cast-iron graphite and blast-furnace graphite were the purest, the latter two contg. no S, H and N. Graphite, retort carbon and coke are oxidized by an alk. melt; the time of reaction is a function of the combustibility of each modification. Graphitic acid was prepd. from Acheson graphite, Ceylon, Russian, blast-furnace, Sibirian, Italian, Corean and cast-iron graphite; it varied in the above order for C from 56.27 to 51.31%, H 1.80–2.18%, O 41.43–46.51%. R. D. Bumbacher

Some substances analogous to graphite. II. Ricardo Ciusa. R. Univ. Bari. *Gazz. chim. ital.* **58,** 222–3(1928); cf. *C. A.* **20,** 736, 2870.—Dry hexahydrobenzene was heated *in vacuo* at 400° in a sealed tube, the product was then heated in a current of N_2 at 540°, 650° and 770° and the elec. resistance and d. of the 3 products and of Ceylon graphite were compared. The following data give the resistance (in ohms) and the d. of the 4 graphites: made at 540°, 245.63, 0.7; made at 650°, 7.05, 1.6; made at 770°; 0.15, 2.0; Ceylon graphite, 0.11, 2.25. The graphite made at 770° is very similar to natural graphite. C. C. Davis

Precious stones. George F. Kunz. *Mineral Ind.* **36,** 491–513(1927).—Diamonds, emeralds, opal, pearls, sapphires and other stones are discussed with reference to sources and production. A. B.

Commercial caseins. Marc Fouassier. *Bull. soc. hyg. aliment.* **16,** 218–29 (1928).—A brief discussion of the production and characteristics of industrial (rennet and lactic caseins) and alimentary caseins (acid casein). Expts. are described showing the survival of *B. subtilis, B. tyrothrix* and probably *B. tenuis* in milk which has been boiled. Their effects on milk are briefly discussed. The first part of the article is also in *Ann. fals.* **21,** 340–2(1928). A. Papineau-Couture

Properties and use of adhesives. J. Wetzler. *Kunstdünger Leim. Ind.* **34,** 332–3, 343–4; *Chem. Zentr.* **1927,** II, 2031.—A summary of the production, properties and use of *adhesives from egg and blood albumins.* They are distinguished by their waterproof quality and are indispensable for adhesive use where the object is exposed to warm, moist air. C. C. Davis

Chemical utilization of bones in Czechoslovakia. Ad. Šonka. *Chemický obzor* **1,** 359–62(1926); *Chem. Zentr.* **1927,** II, 1000.—The author summarizes the different ways in which bones are chemically utilized. They are the starting material for bone fat, glue and gelatin, spodumene and charcoal, fodder lime and bone meal. He mentions the quantities of energy required in this industry. G. Schwoch

Heat consumption of gas-fired lime kilns. H. Hälbig. *Arch. Wärmewirt.* **9,** 143–4(1928).—A good example of an installation with coal-fired producer used 1179 cal. per g. of lime produced. Another, with bad coal, used 1600 cal. One using brown coal used 1173; very wet brown coal cannot be used. A small exptl. unit showed that blast-furnace gas can be used—even for dolomite, if gas and air are preheated. Ernest W. Thiele

Rotary furnaces for pyrites burning. C. P. Debuch. *Papierfabr.* **25**, *Tech.-Wiss. Teil* 365–79(1927); cf. *C. A.* 22, 2910.—Constructive details in the adaptation of rotary furnaces for the burning of pyrites, with illustrations. J. L. Parsons

Testing liquid insecticides. C. H. Peet and A. G. Grady. Rohn and Haas Labs. *Soap* 4, 95–9, 113–5(1928). E. Scherubel

Studies on the toxicity of hydrocyanic acid. James B. Allison. Iowa State Coll. *Iowa State Coll. J. Sci.* 2, 243–52(1928).—The cockroach, rice weevil and albino rat were exposed to varying concns. of HCN derived from liquid HCN, from NaCN and from $Ca(CN)_2$. The data are presented in tables, in plane curves and in a solid figure. In the solid figure the axes represent time, concn. and % kill. The data do not indicate any difference chemically or in toxicity effect between the HCN from liquid HCN and NaCN and that generated from Calcyamid. M. ps. varying from 65° to 92° for different samples of Me Hg cyanide indicated the presence of isomers. The equation, toxicity = concn. × time, holds in only a limited range which may be different for different toxic agents, and different for different animals for the same toxic agent. F. E. Brown

Studies in insecticidal activity. I. Testing insecticides against flies. C. H. Peet and A. G. Grady. Rohn and Haas Co., Bristol, Pa. *J. Econ. Entomol.* **21**, 612–7(1921). **II. Direct contact sprays.** *Ibid* 617–20. **III. Testing insecticidal fumigants—*i. e.*, insecticides which function in the vapor phase.** *Ibid* 621–3. **IV. Testing insecticides as insect repellents and moth killers.** *Ibid* 624–5.—In making comparative tests of household insecticides which act on flies by volatilization or air float, variables should be reduced to a min. A definite standard of time, temp., humidity, insecticide concn., spray concn., spraying pressure, air condition, angle of spray, kind and condition of insect, should be adopted. Many tests and extended observations are necessary. Directions for conducting tests on flies are given. A standard method is described in detail for testing sprays which act upon the insect by direct contact. A math. formula which expresses the effectiveness is included. The method is adapted to the use of water-sol. compds., emulsions and solids in powder form. The cockroach (*Blatella germanica*) and the leather beetle (*Dermestes vulbinus*) have proved to be excellent test insects. A procedure is also given for testing fumigants for insects in storage warehouses, grain elevators, etc., and for testing insecticides and repellents against clothes moths. C. H. Richardson

Carbon disulfide in combating unhealthful vermin. Th. Saling. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 2, 184–8(1926); *Chem. Zentr.* **1927**, II, 1734–5.—A serious warning is given against the use of CS_2 by evapn. to a gas. Far less dangerous is the combustion of CS_2 to which has been added 10% of equal parts of water and alc. C. C. Davis

Sulfur dioxide in combating unhealthful vermin. G. Kunike. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 2, 192–4(1926); *Chem. Zentr.* **1927**, II, 1735.—The essential facts in connection with the combustion of S and S prepns. are discussed. C. C. Davis

Studies in breeding insects throughout the year for insecticidal tests. I. Houseflies (Musca domestic). A. G. Grady. Rhom and Haas Co., Bristol, Pa. *J. Econ. Entomol.* **21**, 598–604(1928). **II. Leather beetles (Dermestes vulpinus Fab.).** *Ibid* 604–8. **III. Roaches, clothes moths, weevils.** *Ibid* 608–12.—Largely biol. with data on the use of these insects in insecticidal expts. C. H. R.

Investigations of the control of the Khapra beetle (Trogoderma granarium, Everts) with calcium cyanide. H. W. Miles. Victoria Univ., Manchester, Eng. *Bull. Entomol. Research* **18**, 251–5(1928).—These beetles may be controlled in malt bins by dosages of Ca cyanide of 2 lb. per 1000 cu. ft. Several fumigations during a summer are necessary for the best results. C. H. Richardson

"Tetra" fire extinguishers and phosgene formation. J. Voigt. *Z. angew. Chem.* **41**, 501–2(1928).—Commenting upon an article by Glaser and Frisch (cf. *C. A.* **22**, 3742–3) V. shows that although $COCl_2$ formed from CCl_4 and air may run high under certain exptl. conditions, yet the fact that so few accidents have occurred from fire extinguishers contg. CCl_4 and other chlorides, although many thousands of them are in daily use, indicates that the danger from this source is not as great as is assumed sometimes. W. C. Ebaugh

Flame speed of H_2S (Chamberlain, Clarke) **2.** Al and bauxite (Anon). **9.** Economic symposium on N (Haynes, *et al.*) **13.** Pb as a constructional material for chemical plant (Tungay) **9.** Catalytic reactions of gases (U. S. pat. 1,686,349) **13.**

Paint or waterproofing material (U. S. pat. 1,684,593) **26.** Catalytic oxidation (Fr. pat. 635,717) **13.**

Reactivating adsorbent substances. METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 285,480, Feb. 18, 1927. The adsorption medium is charged with a "scavenging medium" before use; *e. g.*, C to be used for removing benzine vapor from gases is previously moistened with water and reactivation is effected by heating to generate steam from the water.

Purifying hydrogen, argon, etc. GENERAL ELECTRIC CO., LTD., and C. J. SMITHELLS. Brit. 284,808, Nov. 25, 1926. H or rare gases such as A alone or mixed with H are freed from water, O and other oxidizing impurities by passing over metallic Cr heated to 700–850° (suitably after a preliminary purification with Cu heated to redness and with P_2O_5). The use of hot W and Na is mentioned also.

Sulfuric acid. SOC. GÉNÉRALE METALLURGIQUE DE HOBOKEN. Brit. 284,208, Jan. 24, 1927. In making H_2SO_4 from cold sulfurous gases, the acid is denitrated by a stream of hot sulfurous gases in a tower preferably filled with pieces of inert material of irregular form and of an av. size of less than 40 mm.

Sulfuric acid. SOC. GÉN. METALLURGIQUE DE HOBOKEN. Fr. 635,506, June 3, 1927. Concd. H_2SO_4 is obtained in the chamber process by denitrating the acid with cold sulfurous gas and concg. the denitrated acid in a sep. app. placed between the denitrator and the roasting furnaces.

Hydrobromic acid. N. BOZHOVSKII AND P. T. DANILCHENKO. Russ. 3647, Sept. 30, 1927. A mixt. of Br vapor and steam is passed through red-hot carbon.

Condensation of phosphoric acid. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES DE PRODUITS CHIMIQUES DU NORD REUNIES, ÉTABLISSEMENTS KUHLMANN. Fr. 635,765, June 10, 1927. H_3PO_4 in the form of a gas from the oxidation of P is condensed in a tower by a stream of H_3PO_4, at a temp. and concn. such that the resulting acid is at a required concn., and the incompletely extd. gas leaving the tower is at such a temp. that the steam therein will not condense. The residual H_3PO_4 is extd. with pumice stone, coke, porcelain, etc.

Apparatus for making hydrocyanic acid. M. A. GUSEV. Russ. 4319, Sept. 15, 1924.

Removing carbon dioxide from gases. I. G. FARBENIND. A.-G. Brit. 284,574, Oct. 24, 1927. In scrubbing gases such as those to be used for NH_3 synthesis, as described in Brit. 271,852 (*C. A.* **22**, 1637), aq. NH_3 is used as the scrubbing liquor in the first of a series of towers and gypsum liquors are used in the later towers. The gypsum liquors are obtained from the sediment formed in the prepn. of $(NH_4)_2SO_4$ from gypsum, NH_3 and CO_2, by suspending the sediment in water, filtering it through coke, and dilg. with water.

Acid and salts strongly absorbing ultra-violet rays. TSUNEO SUZUKI and SUEO SAKURAI (to Zaidan Hojin Rikagaku Kenkyujo). U. S. 1,684,562, Sept. 18. In prepg. a condensation product of sugar and a parasulfonic acid compd. of phenylhydrazine, an aq. soln. of an osazone-forming sugar such as grape sugar or invert sugar is heated with a *B*-sulfonic acid compd. of phenylhydrazine in quantity sufficient to form an osazone and with NaOAc until the soln. assumes a dark yellow color, and the condensation product is pptd. with alc. It may be used in *paints, pigments*, etc., which are opaque to ultra-violet rays.

Storing alkali metals or similar oxidizable material. DOROTHY H. BROPHY AND WILLIAM A. RUGGLES (to General Elec. Co.). U. S. 1,685,666, Sept. 25. The material is placed under oil, a capillary tube in a casing closed at its lower end is inserted through the oil and into the material (such as alkali metal), the lower end portion of the casing is removed, and the tube is filled with the metal or other material to retain it for storage.

Synthesis of ammonia. GEORG FRIEDRICH UHDE. Fr. 635,933, Apr. 28, 1927. The mixt. of N and H is heated to a moderate temp., 300–400°, before entering the reaction furnace, and transmits the heat to the furnace and contact materials.

Apparatus for ammonia synthesis. GEORGES CLAUDE (to Lazote Inc.). U. S. 1,686,799, Oct. 9. An outer pressure-sustaining vessel or tube is provided with a head or closure which carries a conduit for the gases; this conduit extends into the app. beyond the closure and carries on its inner extension an inner tube contg. the catalyst. Various structural details of the app. are described.

Apparatus for ammonia synthesis. GIACOMO FAUSER. U. S. 1,686,371, Oct. 2. A reaction chamber is surrounded by a pressure-resisting wall (spaced from the reaction chamber) and a heat-exchanger is located in the space between the reaction chamber and surrounding wall. This heat-exchanger is formed of tube sheets and tubes ex-

tending longitudinally of the reaction chamber, and the reaction chamber is surrounded with heat-insulating material, the thickness of which varies directly with the temp. gradient in the heat-exchanger.

Separation of ammonia from gases. GEORG FRIEDRICH UHDE. Fr. 635,932, June 13, 1927. NH_3 is sepd. from gases, particularly from N and H, by allowing liquid NH_3, obtained by a previous incomplete liquefaction, to vaporize and pass countercurrent to the gaseous mixt. to be treated, thereby cooling and freezing the NH_3 therein.

Alkali metal salts of organic compounds. KARL DOBMAIER (to I. G. Farbenind. A.-G.). U. S. 1,685,191, Sept. 25. Org. compds. such as chlorobenzoic acid or Hg derivs. are treated with PhONa, Na β-naphtholate or other suitable alkali metal salts of hydroxylated aromatic compds.

Salts from sea water. DEMETRIUS G. ZALOCOSTAS (to The Salt Production Syndicate Ltd.). U. S. 1,684,935, Sept. 18. Sea water is evapd. at a high temp. until a concn. is reached below that at which $CaSO_4$ is pptd., the concd. brine is transferred to another closed chamber, the heating surfaces of which are maintained at a temp. of about 38° and which is under sufficient vacuum to produce rapid evapn. at that temp. so that $CaSO_4$ is pptd. as a mud; the strong brine is then transferred to another evaporator and the evapn. is continued for the pptn. of NaCl and the residual liquor contg. the bitterns is finally removed.

Complex hydrofluoric salts. MAX BUCHNER (to Albert Meyerhofer). U. S. 1,685,628, Sept. 25. An alk. earth metal fluoride such as CaF_2 is treated with a fluoride of Si or B in the presence of a salt of an alkali metal such as NaCl, the complex hydrofluoric salt of which metal is to be produced.

Double carbonate of sodium and magnesium. HANS RUBINSTEIN. U. S. 1,684,-782, Sept. 18. $MgCO_3$ is treated, in the presence of an alkali metal chloride and while heated (suitably at a temp. of about 60–70°), with an excess of soda in soln.

Treating metallic oxides. ALUMINIUM COMPANY OF AMERICA. Fr. 32,581, Nov. 27, 1926. Addn. to 622,313. Impurities are eliminated from Al_2O_3 in the liquid state in the elec. furnace, and the remaining impurities in the hollow-blown globules of Al_2O_3 are removed by leaching with a reactive acid such as H_2SO_4 and washing.

Nitrites. EUGENE T. DRAKE (to Cudahy Packing Co.). U. S. 1,685,629, Sept. 25. To effect the bacteriological conversion of nitrates into nitrites, a series of cultures is formed of an aq. soln. of $NaNO_3$, sugar, NaCl and "amino-nitrogen" (such as a meat juice prepn.) with selected groups of non-putrefactive, non-pathogenic, nitrate-reducing, non-proteolytic, motil and non-motil, salt-tolerant bacilli capable of converting nitrates into nitrites and cultures so prepd. are used for treating nitrate.

Alumina. T. SUZUKI, H. TANAKA and T. KURITA. Brit. 284,661, Feb. 3, 1927. In order to obtain pure alumina from alumina contg. Si, Fe, ferro-Si or oxides of Fe, the material is treated with Cl or HCl gas at temps. above 200° and reducing agents such as C or CO also may be used. Various details are given.

Separating alumina from alum. GEORGE S. TILLEY. U. S. 1,686,112, Oct. 2. Crystd. K alum is heated to a temp. (suitably about 80–85°) substantially below that at which it would melt in its H_2O of crystn., the temp. is maintained for a sufficient time to remove over half of the H_2O of crystn., and the material is thereafter heated to a sufficiently higher temp. (suitably about 800–1000°) to drive off the SO_3 which is initially combined with the alumina. The material may then be leached to sep. the alumina as an insol residue. The SO_3 produced may be absorbed in strong H_2SO_4 to produce still stronger acid.

Separation of aluminum hydroxide from solutions of aluminates. B. G. VISHNEVSKII. Russ. 3985, Nov. 30, 1927. $Al(OH)_3$ is formed by the action of CO_2, SO_2 or H_2S or their alkali salts.

Synthetic ammonia. GEORGE F. UHDE. U. S. 1,685,734, Sept. 25. NH_3-forming gases are brought into contact with a catalyst comprising the dried reaction product of a complex alkali metal Fe cyanide compd. such as $K_4FeC_6N_6$ or $K_3FeC_6N_6$ with a hydrolyzable metal salt such as $AlCl_3$. Cf. *C. A.* **22**, 2035.

Ammonium chloride. IMPERIAL CHEMICAL INDUSTRIES LIMITED. Fr. 635,626, June 8, 1927. NH_4Cl is prepd. from gaseous NH_3 and HCl in the presence of H, the residual H_2 being used for the synthesis of NH_3 or HCl, making a cyclic process. Cf. following abstract.

Crystals of ammonium chloride. IMPERIAL CHEMICAL INDUSTRIES. Fr. 635,627, June 8, 1927. NH_4Cl is obtained in crystal form by the reaction of gaseous NH_3 and HCl, dild. with H, at sufficient speed, and in heat-insulated chambers to obtain a high reaction temp. Cf. *C. A.* **22**, 3497 and preceding abstract.

Barium ortho- or trisilicate. RHENANIA-KUNHEIM VEREIN CHEMISCHER FABRIKEN

A.-G. Fr. 636,045, June 16, 1927. Ba ortho- or trisilicate is prepd. by heating $BaCO_3$ with silicic acid or Ba metasilicate in the presence of steam, thereby lowering the temp. necessary. The steam may be led in with the furnace gas, or a gas contg. sufficient H to form the necessary steam may be added.

Calcium cyanamide. JOSEPH RAITZYNE. Fr. 32,584, Nov. 29, 1926. Addn. to 628,303. The action of NH_3 on $CaCO_3$ is carried out in the presence of small quantities of metals such as Fe or oxides which increase the formation of $Ca(CN)_2$.

Calcium polysulfide. CHARLES D. WOOD (to Los Angeles Chemical Co.). U. S. 1,685,895, Oct. 2. S is ground in the presence of lime and hot water.

Magnesia. STEIRISCHE MAGNESIT INDUSTRIE. Austrian 109,012, April 15, 1924. Magnesite is heated to 500–600°, at which temp. $MgCO_3$ is decomposed but $CaCO_3$ remains unchanged. MgO is then sepd. by taking advantage of its great friability, the calcined product being gently triturated so that substantially only the MgO is pulverized.

Potash salts from wyomingite, etc. ROBERT D. PIKE and ROSS CUMMINGS (Cummings' interest to Pike). U. S. 1,686,835, Oct. 9. A fine ground pulp of mineral such as wyomingite is treated under heat and pressure with a soln. of NaCl contg. a small proportion of $NaHCO_3$.

Potassium chlorate and chloride. E. I. SHPITALSKII and Z. A. IOFFE. Russ. 4354, Jan. 31, 1928. Cl_2 acts on such a concn. of K_2CO_3 as to ppt. out finally the KCl at an elevated temp. in a solid form. To convert the K_2CO_3 into $KClO_3$ without any side reaction, such as the decompn. of KClO into KCl and O_2, the first stage of the reaction of satg. K_2CO_3 with Cl_2 in which bicarbonate is formed and the highest concn. of hypochlorite is reached is carried out at a moderate flow of Cl_2 and at low temp. In the second stage, to obtain an acid soln. which favors the transformation of KClO into $KClO_3$ the temp. of the soln. is gradually raised and excess of Cl_2 is admitted.

Sodium bicarbonate and ammonium chloride. BERNHARD LOPMANN. Can. 283,687, Oct. 2, 1928. First NH_3 and CO_2 and thereafter NaCl are made to act on a soln. contg. besides the bicarbonate and chlorides of Na and NH_4, a readily sol. auxiliary salt of one of the two bases and of an acid other than HCl and CO_2; NH_3 is introduced into the soln. during pptn. of the NH_4Cl; the pptd. solids are sepd. from the liquor by filtration; and the filtrate is treated with CO_2 to convert the $(NH_4)_2CO_3$ formed in the soln. into NH_4HCO_3.

Sodium sulfide. B. LAPORTE, LTD. (M. Schlaugk Ges.). Brit. 284,958, Sept. 21, 1927. Solns. of Na sulfide are freed from Fe by treatment with a cyanide, *e. g.*, by heating to 85–90° with 0.2–1.0% NaCN. Colorless crystals may be obtained from the purified soln.

Tungsten oxide gel. WALTER A. PATRICK and EARLE H. BARCLAY (to Silica Gel Corp.). U. S. 1,683,695, Sept. 11. An acid such as HCl or H_2SO_4 is added to a soln. of Na tungstate or other suitable tungstate in such proportion that the final acidity after reaction will be 0.1–0.5 *N* the addn. of acid is stopped on the appearance of a ppt. until the ppt. redissolves on stirring, and more acid may then be added; the sol is allowed to set to a hydrogel, and is washed and partially dehydrated. Cf. *C. A.* **22**, 3965.

Zinc carbonate. N. A. LAURY. Brit. 285,260, March 7, 1927. Roasted Zn ore is heated to about 80° in a 20% aq. $(NH_4)_2SO_4$ soln., the clear soln. is sepd., cooled and satd. with CO_2 under a pressure of 20 lbs. per sq. in. Cf. *C. A.* **21**, 3429.

Calcining alkaline earth carbonates. REED W. HYDE (to Dwight & Lloyd Metallurgical Co.). U. S. 1,684,958, Sept. 18. Small particles of carbonate such as limestone, dolomite or magnesite are mixed with a small proportion of solid fuel, *e. g.*, coal, and the mixt. is spread in a layer of uniform thickness and permeability, and independently heated gases are passed through the layer to burn out the solid fuel and rapidly heat the carbonate to a temp. below the incipient fusion point and above the decompn. temp. to convert the carbonate to oxide. An app. is described. Cf. *C. A.* **22**, 1454.

Hydrogen. MME. CASALE (Née MARIA SACCHI). Fr. 635,946, June 14, 1927. A mixt. of O and CO_2 is passed over incandescent charcoal, and the CO formed is purified and led with steam over catalysts to produce H and CO_2. The O may be mixed with N to obtain a final mixt. of N and H for the production of NH_3. Cf. *C. A.* **22**, 3497.

Hydrogen. J. BELLAY. Brit. 284,262, Jan. 26, 1927. See Can. 282,952 (*C. A.* **22**, 4213).

Hydrogen by dissociation of hydrocarbons. RUDOLF BATTIG. Fr. 635,670, May 18, 1927. In the decompn. of hydrocarbons, particularly CH_4 for the production of H, the gas passes through a preheating chamber, through a chamber where it is heated to dissocn. temp., and then through a chamber where the C is continuously extd. by coke

or Fe. The H passes on to a chamber where its heat is absorbed. Air is then passed in the reverse direction to burn the C deposit and reheat the first chamber.

Phosphorus. I. G. FARBENIND. A.-G. Brit. 285,055, Feb. 10, 1927. Raw phosphates, C and material contg. SiO_2 and Al_2O_3 are heated together in such regulated proportions as to produce P and H_3PO_4 and a slag having a compn. similar to blast-furnace slag and suitable for the production of *slag cement, e. g.*, by grinding with portland cement clinker.

Oxidation of phosphorus. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES DE PRODUITS CHIMIQUES DU NORD RÉUNIES, ÉTABLISSEMENTS KUHLMANN. Fr. 635,501, June 3, 1927. Phosphides, particularly phosphides of Cu or Ni, are used as catalysts for the oxidation of P in the presence of steam. The phosphides are prepd. by the action of H_3P on solns. of metallic salts distributed on suitable supports, such as calcined bone, coke, porous blocks of SiC, Fe-Si, Ni-Cr or silicophosphides of Fe.

Oxy-compound of phosphorus. CLAUDE G. MINER (to Phosphorus Hydrogen Co.). U. S. 1,686,873, Oct. 9. Reaction of H_2O on P is effected in the presence of an alkali metal such as K which is intermixed with the P in the form of a condensate and serves to facilitate the reaction

Sulfur and calcium sulfide. ALBERT GALLETTI. Ital. 251,496, Feb. 12, 1926. Process for working minerals with SO_2 to obtain S and Ca sulfite. Addn. to Ital. 241,099, June 27, 1925.

Sulfur. AUGUSTO DELL'AMORE. Ital. 246,312, Feb. 18, 1926. Economical process for heating fusion ovens for S minerals at a low temp. A special oven is specified.

Sulfur. VINCENZO MORANI and ROBERTO VERDERAME. Ital. 248,955, May 19, 1926. Process for the combustion of minerals in the S pits with successive transformation of combustion compds.

Sulfur. VISCOSA SNIA and GIUSEPPE GUADAGNI. Ital. 245,595, Jan. 12, 1926. Oven with heat recovery for complete extn. of S from minerals.

Sulfur recovery from furnace gases. WM. H. HOWARD. U. S. 1,685,231, Sept. 25. Furnace gases contg. SO_2 are passed in contact with a body of water to form a soln. of SO_2; a current of air is utilized to take up the SO_2 from the water and the mixt. of air and SO_2 is subjected to the action of incandescent carbonaceous material to form elemental S.

Concentration of highly diluted iodine solutions. O. YU. MAGIDSON. Russ. 4561, Sept. 15, 1924. Weak solns of I treated by one of the known methods to sep. I in the form of the element are passed through a starch suspension until it is satd. The I absorbed is then extd. from the starch by a soln. of Na_2SO_3 or other reagents which change the I into HI or its water-sol. salts.

Active carbon. VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Brit. 285,386, Feb. 14, 1927. The acidity of C which has been activated by use of acid substances or those which develop acidity is removed by treatment under pressure with milk of lime, Na_2CO_3, NaOH or other alk. substance at temps. of 100–150°.

Activated carbon. SOCIÉTÉ ANON. DES ENGRAIS ET NOIR ANIMAL. Fr. 635,832, Oct. 6, 1926. Activated charcoal of high density is obtained by treating the carbonaceous material with a small proportion of HNO_3 during charring.

Activated charcoal. RICHARD THRELFALL. Fr. 635,239, May 30, 1927. See Brit. 270,505 (*C. A.* **22**, 1658).

Apparatus for activation or revivification of carbon. STANLEY A. W. OKELL and LEONARD WICKENDEN (to Industrial Chemical Co.). U. S. 1,686,100, Oct. 2. A long shallow trough is provided with a longitudinal series of rakes which oscillate longitudinally to and fro and gradually propel the charge from rake to rake through the trough, while it is electrically heated.

Electrodes and other articles formed of carbon. I. SZARVASY. Brit. 284,818, Dec. 6, 1926. See U. S. 1,675,674 (*C. A.* **22**, 3101).

Furnace (with superposed hearths and stirring devices) for revivifying decolorizing carbon, etc. JOSEPH H. HOLT (to Darco Corp.). U. S. 1,685,745, Sept. 25.

Mica. VASSALLO ALDO and GRONDONA PETRO. Ital. 245,456, January 9, 1926. A recovery process.

Borax from rasorite. THOMAS M. CRAMER (to Pacific Coast Borax Co.). U. S. 1,685,214, Sept. 25. The material is treated with water or a mother liquor at a temp. substantially above 100°. Live steam also may be used. Cf. *C. A.* **22**, 3497.

Reaction tower and heat-exchange device for causticizing sodium carbonate while bubbling hot gas such as air and steam through the materials. WILLIAM D. MOUNT. U. S. 1,685,929, Oct. 2.

Fuller's earth and other adsorbents. R. R. ROSENBAUM. Brit. 284,327, Jan. 29, 1927. Fuller's earth or other adsorbent is activated or regenerated by treatment with liquid SO_2, preferably in the filter used for purification of hydrocarbons, oils, waxes, etc. (and suitably after preliminary treatment with steam to remove most of the adsorbed oil, etc.). An app. is described.

Adsorption agent containing carbon. OSKAR SCHOBER. Fr. 635,781, June 10, 1927. A carbonaceous material rich in ash or substances capable of producing ash is treated at activation temp. with oxidizing agents, gases or vapors till the final product contains at least 20% of ashes sol. in HCl.

Adsorbents from zeolitic material. A. ROSENHEIM. Brit. 284,245, Jan. 25, 1927. The process of treating zeolitic material with acids or acid salts for the production of adsorbents as described in Brit. 275,203 (*C. A.* **22**, 2248) is carried out by adding the acid or acid salt gradually or intermittently to a suspension of the material in water, preferably with heating, so that solid non-gelatinous products are obtained. The zeolitic material may be preliminarily heated to 300–800° and the product of the treatment may be formed into briquets with a binder such as waterglass or resin which may, if desired, be subsequently removed. Examples and details are given.

Removing incrustations formed from milk on hot metallic surfaces. R. SELIGMAN. Brit. 284,778, Nov. 4, 1926. The surfaces are treated with an acid contg. casein or gelatin, *e. g.*, an aq. soln. contg. H_3PO_4 2 and casein 1% at 85–100° which may be circulated over the metal surface to be cleaned. The casein or gelatin serves to minimize or prevent action of the acid on the metal itself.

Phosphatides. PHARMAGANS PHARMACEUTISCHES INSTITUT L. W. GANS A.-G. Brit. 285,417, Feb. 16, 1927. Lipoids such as phosphatides are extd. from materials contg. them by dialysis without destruction of the cellular structure; *e. g.*, peas and beans may be treated with water or dil. alc. at a temp. not exceeding 37°. The phosphatides are removed from the dialyzing liquid by adding fat-dissolving substances such as alc. or acetone, which cause pptn. of the phosphatide. Adsorbents also may be used to effect the sepn. The dialysis may be accelerated by the use of a difference of elec. potential of a "few hundred volts" between electrodes in an app. which is described. Various modifications and details of the process are given.

Albumins. HENRI BEAUFOUR. Fr. 32,707, July 2, 1926. Addn. to 617,280. Sea water is used to dissolve the albumins contained in plants or parts of plants. A treatment with lime or other alk. earth hydroxide may precede or follow the treatment with sea water. Cf. *C. A.* **21**, 3433.

Water-soluble "silicate-albumins." J. A. VON WULFING and A. BUSCH. Brit. 284,450, Jan. 11, 1927. Alkali metal polysilicates are combined with casein or albumin substances of acid character, such as nucleoalbumins or albuminates, and an alkali such as NaOH, to obtain neutral or weakly acid water-sol. metasilicate albumin prepns.

Softening and waterproofing formolized casein and cellulose products. GASPARD JAKOVA-MERTURI and JOSEPH-ALFRED POGGIOLI. Fr. 635,637, June 8, 1927. Products having a basis of formolized casein or cellulose such as cellulose acetate or celluloid are treated in the warm in a bath of KOCl and (or) NaOCl and KOH, this treatment being followed by an immersion in a bath of mineral or vegetable oil contg rosin and S.

Metal glutins. KARL KÜTTEL (one-fourth each to Ernst J. Watzl and Herman J. Trenkamp). U. S. 1,686,281, Oct. 2. Metal glutins which can be used as substitutes for casein or bakelite in making various articles are prepd. by treating a soln. of glutin (suitably a 20% aq. soln. of glutin derived from animal wastes contg. ossein) with only such a quantity of an alkali such as NaOH as is required to transform all of the glutin into satd. alkali metal glutin, and then treating the latter with a suitable metal salt such as $Al_2(SO_4)_3$ or $ZnSO_4$ (suitably at a temp. of about 28°). The products are ductile while warm and become set and retain their shape when cool.

Machine bearings formed in part of bakelized wood. MANUFACTURE DE MACHINES AUXILIARES POUR L'ELECTRICITE ET L'INDUSTRIE. Brit. 284,654, Feb. 2, 1927. Structural features.

Urea-formaldehyde condensation products. KURT RIPPER (to Fritz Pollak). U. S. 1,687,312, Oct. 9. Water-sol. initial products are formed in 2 stages by adjusting the C_H in the first stage, which is completed after heating for a short time, to a value not exceeding about 10^{-7} and in the second stage to a value above 10^{-7} but below 10^{-3} and then the reaction is continued by further heating.

Composite molded articles such as caster wheels formed in part of phenolic condensation product and in part of rubber. LE BONSIEUR. U. S. 1,686,142, Oct. 2. Structural features.

Meltable adhesive. ERSKINE D. LORD (to McLaurin-Jones Co.). U. S. 1,684,873,

Sept. 18. A meltable waterproof adhesive suitable for use on paper or cloth sealing strips is formed of a fatty acid pitch and a smaller quantity of wax, *e. g.*, stearin pitch and paraffin with or without asphalt.

Plastic condensation products. SOC. ANON POUR L'IND. CHIM. À BÂLE. Brit. 284,589, Jan. 29, 1927. Condensation products from aniline and CH_2O or the like, formed in the presence of an acid such as HCl, are treated, at any stage of their production, with NaOH soln. or other suitable agent to eliminate the acid and produce a homogeneous, easily worked product which can be dried and compressed in molds while comminuted (suitably at 150° under 160 atm. pressure for 1.5 hrs.).

Dehydration of plastic condensation products of phenols and aldehydes. G. S. PETROV. Russ. 4328, Jan. 31, 1928. The products are heated at 100–180° in drying or semi-drying oils at ordinary or reduced pressure.

Plastic preparation. A. I. IEVLEV. Russ. 3429, Aug. 31, 1927. Crude wood pulp and paper mass after wet grinding and pressing off the water is ground with a drying oil and powdered chalk and mixed with a mass obtained by adding asphalt or resin or pitch or S to lime during the process of hydration. Na silicate soln. is added finally to this mixt.

Plastic preparation from peat. S. I. KISLITZUIN. Russ. 3713, Sept. 15, 1924. Any borate, *e. g.*, borax, is added to peat while still wet but sepd. from the aq. soln. after treatment with an aq. soln. of an aluminate.

Plastic compositions. JAROSLAW'S ERSTE GLIMMERWAREN-FABRIK. Fr. 635,745, June 10, 1927. See Brit. 272,947 (*C. A.* **22**, 1832).

Drying metallic powders. RINGSDORFF-WERKE A.-G. Fr. 635,511, June 3, 1927. To avoid oxidation in drying metallic powders, the water is replaced by an alc. or other volatile solvent which will replace water. A centrifuge may be employed.

Coating metallic surfaces. AMI REY. Fr. 635,306, May 23, 1927. Substances rich in C are distd. and the gaseous products are deposited on metallic surfaces forming a protective layer. The surfaces are afterwards dipped in a heated bath of adhesives, such as asphalt or tar.

Metallizing non-metallic surfaces. A. I. G. WARREN and PRECIOUS METAL INDUSTRIES, LTD. Brit. 284,786, Nov. 5, 1926. Surfaces such as those of wood, bone, ivory, phenol CH_2O condensation products, celluloid or vulcanized fiber (after a preliminary treatment with HOAc or other agent to open their pores if desired) are treated with an easily reducible metal compd. such as oxide or sulfide of Ag or Au (which may be formed into a fluid mixt. or thin paste with liquids such as $CHCl_3$, oil of turpentine, C_6H_6 or water) and the compd. is then reduced by use of steam under pressure or other suitable means. Some materials may be preliminarily treated with S or CS_2. Cf. *C. A.* **22**, 3129.

Contact oxidation of methane or gas mixtures containing methane. S. S. MEDVEDEV. Russ. 3605, Sept. 30, 1927. The gas or gas mixt. and O or O-contg. gases are heated in the presence of catalysts, heat-resistant at the reaction temp., such as tin borates, tin phosphates or other tin compds.

Impervious chemically resistant material. WARREN F. BLEECKER. U. S. 1,686,-197, Oct. 2. A material suitable for pipe linings, etc., is formed of artificial graphite, S, and solid hydrocarbons such as pitch.

Coating flues, etc., to render them impermeable to flowing gases. P. E. J. J. COURTURAUD (to Laboratoire de perfectionnements thermiques). Brit. 284,219, Jan. 24, 1927. Either the interior or exterior (or both) of flues or conduits (or the bricks from which they are made) are coated with Na silicate soln. or other sol. silicate soln., which may also be mixed with graphite.

Waterproof packing cloth. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 635,537, June 4, 1927. Linen or other cloth is impregnated and covered with a mixt. of soft and adhesive pitch, *e. g.*, calking pitch and a non-drying oil to prevent hardening of the pitch. The cloth may be given a layer of sawdust.

Wetting agents. FARB- UND GERBSTOFFWERKE G. FLESCH (to H. Flesch). Brit. 284,249, Jan. 26, 1927. Highly sulfonated oils such as the sulfuric esters of dihydroxystearic acids having a content of 6% or over of "organically combined sulfuric acids" may be added to various solns. and emulsions such as those used in the *textile industry* to improve their wetting and penetrative capacity and cleansing properties. Various examples are given.

Friction material for brakes, clutches, etc. KIRCHBACH'SCHE WERKE KIRCHBACH & CO. Brit. 284,268, Jan. 26, 1927. Structural details are given of asbestos impregnated with bakelite or similar impregnated fibrous material assocd. with metal rings

or the like on which driving teeth may be formed. Brit. 284,269 specifies treating a mixt. such as fibrous material and bakelite, without heating, under very high pressure (suitably 5 tons per sq. cm.) and subsequently baking (suitably for several hrs. at 150–200° after preliminary drying at normal temp. for 14 days or longer). An app. is described. Cf. *C. A.* **22**, 1832.

Machine bearings of asbestos or other fibrous material impregnated with an artificial resin. Kirchbach'sche Werke Kirchbach & Co. Brit. 285,078, Feb. 12, 1927. Graphite or metal such as fine brass wires may be assocd. with the fibrous material.

Self-lubricating bearing. Joseph Brincil. U. S. 1,686,951, Oct. 9. The surface of a metal bearing which may be formed of bronze is abraded and then provided with a spongy layer of graphite and powd. bearing metal united (by use of shellac and pressure) to the abraded metal base.

Oil composition for use in hydraulic brake systems of automobiles, etc. E. D. Evans and C. C. Wakefield & Co., Ltd. Brit. 285,144, Nov. 10, 1926. A compn. which is substantially inert to rubber comprises castor oil and a miscible alc., higher than EtOH, such as cyclohexanol or Bu, Am or benzyl alcs.

Packing for gaskets, rods, etc. Burnie L. Benbow. U. S. 1,686,063, Oct. 2. A "base material" such as flax, asbestos or metal wool is immersed in a liquid bath contg. deflocculated graphite in suspension, then removed and the liquid evapd. to leave a dry adherent graphite coating on the material.

Electrically heated kiln suitable for burning limestone. Gottlieb Keller (to A.-G. Brown, Boveri & Cie.). U. S. 1,687,025, Oct. 9.

Freezing-point depressant suitable for use with water in automobile engine cooling systems. Samuel Isermann and Waldemar Vernet. U. S. 1,687,094, Oct. 9. Glycerol is used together with a sol. amide such as formamide which serves to lower the viscosity of the soln. at low temps.

Preventing adherence of soot to heated surfaces. P. E. J. J. Courturaud (to Laboratoire de perfectionnements thermiques). Brit. 284,218, Jan. 24, 1927. Graphite (which may be mixed with silicate of Na or K) is used for coating heated surfaces of boilers, superheaters, air heaters, retorts, etc., to prevent adherence of soot.

Bituminous linings or coatings for pipes or other metal articles. R. Illemann. Brit. 285,179, Nov. 22, 1926. The required plasticity of bituminous material is obtained by mixing it with a suspension of stone flour in water. Fibrous material also may be added and the product may be prepd. hot and used when either hot or cold.

Composition for filling cracks between wall board sheets, etc. Daniel C. Bruce. U. S. 1,685,981, Oct. 2. A "soap jelly" is mixed with a starch dextrin paste contg. borax, glycerol and oil of cloves and with comminuted fibrous material such as shredded wall board.

Hectographic compound. N. S. Odoyevtzev. Russ. 3959, Sept. 15, 1924. Fat clay is mixed with glycerol and a satd. soln. of $ZnCl_2$ until it reaches the consistency of putty.

Detergents. British Dyestuffs Corp., Ltd., J. Baddiley and E. Chapman. Brit. 284,367, Sept. 21, 1926. An abrasive such as whiting or pumice powder is used together with a sulfonic acid (or its sol. salt) of an aromatic hydrocarbon with a side chain of 2 or more C atoms or obtained by sulfonating mineral-oil fractions of high b. p. or by sulfonating mineral-oil fractions and condensing the product with an alc. Soap or solvents, etc., may be added. The mixt. is suitable for cleaning tiles, walls, stoneware, glass, metals and painted or polished surfaces.

Composition for cleaning silver. Robert B. Hoffman. U. S. 1,685,360, Sept. 25. Diatomaceous earth 100, water 150, $CaCl_2$ 6, Fe_2O_3 1, "ammonia" 1 and oil of citronella 1 part.

Dyeing and polishing pearl chips. George H. Gebhardt. U. S. 1,685,451, Sept. 25. Pearl chips are polished and then subjected to the action of a liquid dye such as an aq. soln. of an aniline dye in the presence of a substance, *e. g.*, H_2O_2, which tends to open the pores of the pearl chips, again polished after dyeing, and treated with a substance such as hot dil. HCl soln. to fix the dye and render the polish more permanent.

Decolorizing agents. Büttner-Werke A.-G. and Friedrich Kleinmann. Fr. 635,916, June 13, 1927. A decolorizing agent for sugar, etc., consists in a very intimate mixt. of hydrosilicates, such as fuller's earth, and active C from the incomplete combustion of colophony, pitch, tar oil, acetylene, gasoline, etc. The mixt. is obtained by wet grinding in such a way that the particles of C and fuller's earth do not sep. in use. Binding agents such as SiO_2 gel may be added.

Stencil sheets. J. Ehrlich. Brit. 284,907, May 13, 1927. Yoshino paper or the like is coated with a colloidal and plastic compn. over which a coating of the spores of *Lycopodium clavatum* is applied to preserve the plasticity of the coating and protect it from moisture. The first coating may comprise gelatin, glycerol and soap, oil or wax or rubber or the like mixed with tempering agents such as cellulose esters.

Sterilizing vegetable bristles or fibers. G. Averseng. Brit. 284,421, Nov. 10, 1926. The material is immersed in water and then in an antiseptic or anti-cryptogamic bath such as $ZnSO_4$, $CuSO_4$ or salicylic acid. The 2 stages of the treatment may be combined by use of a single boiling bath of the antiseptic.

Transfers. H. S. Sadtler. Brit. 284,676, Feb. 3, 1927. A non-absorbent paper is printed with a paste or ink and the surface dusted with a mucilaginous powder such as gum tragacanth which serves to dry the ink and facilitate penetration of the dye from the ink into the wetted fabric or other material in transferring. Mordants such as tannin or metal salts may be added to the ink which preferably contains a water-sol. dye which can be rendered fast by steaming. Cf. *C. A.* **22**, 875.

Sound record films of steel, nickel or other magnetizable material. H. Küchenmeister. Brit. 285,054, Feb. 10, 1927.

Insecticide. N. N. Manotzkova. Russ. 4298, Dec. 31, 1927. A mixt. of naphthalene, camphor, eucalyptus oil, NH_3 soln., NaCl, PhOH, denatured alc. and turpentine with the addn. of thuja oil and sap from the cactus is specified.

Fire-extinguishing composition. G. E. Lyutkevich. Russ. 4109, Nov. 30, 1927. Mustard is added as a foaming agent to the usual ingredients such as soda and NH_4Cl.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Improvements in the glass industry. Arendt. *Sprechsaal* **61**, 201–3(1928).—A general discussion on the German glass industry, number of persons employed, furnaces and types, temps., output per person of different types of ware and how automatic machinery is gradually replacing human labor. R. A. Heindl

Physical properties of glass and their control. Bernard Long. *Rev. sci.* **66**, 370–8(1928).—A review of the properties of different glasses, the methods and app. used in their testing and the factors affecting these properties. P. Thomasset

Changes in the properties of optical glasses. Paul Nicolardot. *Rev. gén. colloïdes* **5**, 445–9, 539–43, 592–8(1927); cf. *C. A.* **20**, 2729; **21**, 4037.—The changes occurring in optical glasses may be profound, as those caused in the interior of the glass by rays of short wave length. The effect of temp. (cooling and annealing) upon the properties of such glasses is well known. Superficial effects may also occur as, *e. g.*, those due to adsorption of gases and liquids on the surface of the glass. The gravest and most frequent superficial changes are described, as well as the diverse methods for detg. which glasses will be most resistant to each type of change. A detailed description is given of the app. and methods for detg. the diminution in the transparency of glass due to adsorption on its surface. A table is included in which the compn. of the various glasses is related to phys. and chem. properties. L. B. Miller

Recent improvements in the manufacture of flat glass. H. K. Hitchcock, *et al.* *Mech. Eng.* **50**, 778–80(1928).—Discussion (cf. *C. A.* **22**, 2249, 4215). E. J. C.

Strained glass. P. Lazarev. Inst. des Silicates de Moscou. *Chimie et industrie* Special No., 441–3(April, 1928).—Rapid cooling of SiO_2 glass to put it in a strained condition increases the hardness and the resistance to mech. action and lowers the d. and the sp. heat. The same effect was observed with borax glass. Under polarized light strained glass is double refracting and exhibits parallel interference surfaces which vary with the form of the piece of glass and which are closer and more numerous near the surface than towards the center. When borax glass is heated to the softening pt. and cooled slowly (annealed) crystals are formed both at the surface and in the interior of the glass. When such a glass is treated with H_2O, soln. does not take place uniformly over the whole surface but gives characteristic corrosion figures at various points: at the pts. where there are crystals the corrosion figures formed are regular, while at the pts. where there are no crystals the forms are curved and less regular. Investigation of strained glass by Laue's method showed it has no cryst. structure. A. P.-C.

Ampoule glass and p_H. Giovanni Issoglio. *Giorn. farm. chim.* **76**, 363–6

(1927).—The ampoules are autoclaved 2 hrs. at 110° with distd. water and compared with Na_2HPO_4-KH_2PO_4 solns. of p_H 7–8.2 with phenol red and bromothymol blue as indicators. MARY JACOBSEN

Classification of neutral glasses. E. BARONI. *Giorn. farm. chim.* 76, 66–71, 93–8 (1927); cf. *C. A.* 20, 975, 1689.—Tirelli's objection that for glasses contg. B hematoxylin (I) is less sensitive than phenolphthalein (II) is immaterial for practical purposes: I is decolorized only by 1% $Na_2B_4O_7$ but indicates it distinctly in concns. of 0.9–0.0005%. On the other hand glasses contg. much more borax than is practically workable (10–25%) gave after autoclaving with water at 134° an immediate and distinct I reaction. Even alk. glasses with the normal B content do not yield more than 186 mg. water-sol. ext., which is far below the inactivating B quantity. Moreover, I always permits the detection of inferior glass. *Ampoules* ought to be tested as follows: Test for acid (formed by decompn. of CaF_2 on fusing) with methyl red at room temp. or after slight heating with water. Autoclave 1 hr. with II at 134° (2 atm.). Sensitiveness: 0.005 mg. NaOH/cc. Glasses with a negative II test are sufficient for most purposes. Autoclave with bromothymol blue: sensitiveness 0.0004 mg. NaOH/cc. Autoclave with water and test with I. Use for all purposes only twice distd. deaerated water. Prepn. of the *indicators:* triturate 0.05 g. *methyl red* in a neutral glass tube with 15 cc. 0.1 *N* NaOH, add 2 drops abs. alc., shake and heat moderately on the water bath until soln. is complete. Dissolve in 100 cc. water, stir, filter and dil. 10 cc. to 400 cc. To 100 cc. water add 1.5–2 cc. of 1% II, immediately before use. In a test tube mix 50 mg. *bromothymol blue* and 5 cc. 0.01 *N* NaOH thoroughly, stir until the reaction is complete, decant, dissolve the residue in 5 cc. pure alc. and add to the combined solns. 90 cc. water. Dil. 20 cc. to 500 cc. I is prepd. in a 0 1% alc. soln. from C. P. crystals. M. J.

The soluble substance yielded by neutral glass in relation to its action on solutions for injection. EDUARDO BARONI. *Giorn. farm. chim.* 77, 223–38(1928); cf. preceding abstr.—Glass of better quality yields on autoclaving up to 0.007–0.008 mg. per ampoule of an inner surface area of 580 sq. mm. The results are always referred to 1-cc. ampoules. For the bromothymol blue test the indicator solns. are acidulated with 2.5, 5, 6, 7, 8, 10, 11, 12 cc. 0.001 *N* HCl/100 cc. Two good glasses *Fiolax* and *Tenax* were autoclaved 1–6 hrs. at temps. from 100 to 134°. Fiolax yielded to the water 0.0008 mg. in 1 hr. at 100° and 0.004 mg. after 1 hr. at 134° or 6 hrs. at 100°. The increases of soly. with temp. and time are irregular. Tenax yielded 0.0006 mg. after 1 hr. at 100°, 0.0028 after 6 hrs. at 100°, 0.0015–0.002 after 1 hr. at 128–34°. The diagram shows parallel unbroken straight lines. That this difference is entirely attributable to the difference in the compn. of the original glass is doubtful for the following reasons. Considerable differences were found for ampoules of the same lot. Expts. showed also that the sol. alkali content of a length of glass tube and of test tubes made from this tube by sealing one end was uniform throughout the entire length. Ampoules, however, made from this tube showed a different alkali content at different heights. It was markedly increased in the drawn out part. Those annealed in the flame had a considerably higher sol. alkali content than normal ampoules (0.005 in Tenax and 0.006 in Fiolax instead of 0.002 and 0.004). Glasses of poor quality suffer a more marked decompn. by heat. MARY JACOBSEN

Important qualities of several glasses used for chemical purposes. O. KALLAUNER AND JOSEF MATĚJKA *Chemicky Obzor* 2, 8–11; *Chem. Zentr.* 1927, II, 969.—The authors examd. several com. brands of chem. app. glass, as Jena glass, Eserco, Kavalier "Palex," Kavalier "S," and Resista. They report shape, surface and appearance of the glass material; measurements, vol. and density of the glass ware; resistance towards sudden change of temp. and towards impact; and the ability to resist the following: H_2O, 1% HCl, 20% HCl, concd. H_2SO_4, 5% NaOH and 5% NH_3. Tables are given for comparison. G. SCHWOCH

Annealing and leaching of chemical glassware. H. LÖBER. *Sprechsaal* 61, 160–2, 181–3(1928).—Glasses of 5 different hydrolytic classes were tested to det. the effect of a leaching soln. (Na_2O) on unannealed chem. glassware (flasks and test tubes) and after annealing one, two and three times. The classes of glassware tested include (1) water-resistant, (2) tough, (3) hard, (4) soft, (5) defective. Values and charts are given to show increased resistance to leaching with each additional annealing treatment. R. A. HEINDL

The viscosity of molten glass. P. LAZAREV. Inst. des Silicates de Moscou. *Chimie et industrie* Special No., 440(April, 1928); cf. *C. A.* 21, 3506.—The viscosity of viscous liquids was studied by 2 methods: (1) calcg. η by detg. the rate of fall of a metal sphere in the liquid, which is done by means of x-rays in the case of molten glass; (2) a cylinder filled with the liquid is rotated about its axis, a second cylinder is suspended

in the liquid by means of a fine metallic thread, and η is calcd. from the force acting on the suspended cylinder. The accuracy of these 2 methods is about 5%. A. P.-C.

Control and improvement of the composition of (glass) hollow ware. Oscar Knapp. *Glass Ind.* **9**, 165-8(1928).—A careful study of the effect of compn. upon the physical properties of glasses should precede any changes in batch compns. Triaxial diagrams for SiO_2, CaO, and Na_2O or $K_2O.Na_2O$ are advised which have double borders so that compn. and also a scale of properties can be included. The important characteristics which are linear functions of the compns. are tensile strength, endurance, expansion, elasticity, density and sp. heat. H. F. K.

The undissolved components of waste water and their determination in setting glasses. C. Zahn. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **1**, 154-9(1925); *Chem. Zentr.* **1927**, II, 1745.—A description of methods and app. C. C. Davis

Tentative method for complete sand analysis. Glass Division, Standards Committee, Am. Ceramic Soc. *Glass Ind.* **8**, 217(1927). H. P. Hood

The influence of magnesium oxide on the resistance of glasses. M. A. Besborodow. *Keram. Rund.* **36**, 365-8(1928).—In a glass with the compn., SiO_2 67.91%, Al_2O_3 3.97, Fe_2O_3 0.03, CaO 9.00, B_2O_3 2.43, Na_2O 9.51, K_2O 7.06 MgO was substituted for CaO in increments of approx. 2% to a max. of 8.27%, the percentage amounts of the other oxides remaining approx. const. The resulting glasses, made up in the form of beakers of 400 cc. capacity, were tested by boiling for an hour with 2*N* NaOH soln. with 2*N* Na_2CO_3 soln. and with 20% HCl soln. After each treatment the loss in weight was detd. The results were as follows. (1) An increase in MgO and decrease in CaO decrease the resistance to NaOH soln. (2) Substitution of MgO for CaO increases the resistance to Na_2CO_3 soln. until a max. is reached at 5.78% MgO. Further increase in MgO causes a decrease in resistance. (3) Substitution of MgO for CaO decreases the resistance to HCl soln. until a min. is reached at 5.78% MgO. Further increase in MgO increases resistance. Observations on the refining and working qualities of the glasses indicate that the viscosity and surface tension of the glasses increase with increasing MgO. The difficulty of melting increases with increasing MgO and in general the substitution of MgO for CaO is not advisable. H. I.

Melting experiments with alumina-bearing rocks. Ludwig Springer. *Keram. Rund.* **36**, 403-6, 426-8(1928).—Glass-melting expts. were performed with a glass of normal compn. and by substituting for quartz sand, either wholly or in part, (1) quartziferous feldspar sand, (2) pumice, (3) greenstone, (4) "Erlan-Gestein," a mixt. of an epidote-bearing granite and epidote- and hornblende-bearing quartzite. The substitutions were so made in general that the % by weight of $SiO_2 + Al_2O_3 + Fe_2O_3$ and of $Na_2O + K_2O + CaO$ were approx. const. Conclusion: (1) Several of these materials have valuable qualities as components of the batch, either as the principal raw material in ordinary glasses, as a coloring medium for green or dark glasses or as admixts. in special glasses. (2) Al_2O_3 in glasses up to a certain amt. is not only not harmful but may be beneficial in improving the chem. stability and assisting in fusion. (3) The use of these substitutes may cause an appreciable saving in alk. batch materials since the rocks themselves contain alkalies or other constituents which are satisfactory as fluxes. (4) Disadvantages of these substitutes are (*a*) the cost of grinding, (*b*) the high Fe content of some of them, (*c*) the difficult fusibility and high viscosity of the glass when too much of the substitutes are used. H. Insley

The heat balance of a glass tank furnace. Robt. D. Pike and Geo. W. West. *J. Am. Ceram. Soc.* **11**, 734-44(1928). C. H. Kerr

Clay products in modern construction. Henri Gilardoni. *Ciment* **33**, 342-9 (1928). F. O. A.

Clays and clay development of Louisiana. J. W. Whittemore. Louisiana State Univ. *J. Am. Ceram. Soc.* **11**, 782-4(1928). C. H. Kerr

Tertiary clays of southern California. Robt. Linton. *J. Am. Ceram. Soc.* **11**, 771-81(1928). C. H. Kerr

Dorr classifiers for clay washing. A. Anable. *J. Am. Ceram. Soc.* **11**, 791-4 (1928). C. H. Kerr

Physico-chemical investigation of the heat-resistant clays from Borowitschi G. G. Urazov and N. I. Vlodavetz. *Ann. inst. anal. phys.-chim. (Leningrad)* **3** 725-45; *Chem. Zentr.* **1927**, II, 2705; cf. **20**, 3789.—*Heating and dehydration curves of hard and soft clays were detd.* The chem. compns. of both kinds and also those of the intermediate ones are almost the same, though the plastic clays contain somewhat more foreign substances, such as feldspar and quartz. All samples contained 13-15% of water. The heating curves show 2 endothermic phenomena, the elimination of hygro-

scopic water at 100–110° and of constitutional water at 320–600° (plastic clays) or 400–600° (non-plastic clays). At approx. 950°, especially with hard clays spontaneous heating occurred, so that the temp. of the substance exceeded in many cases by 150° that of the furnace. The dehydration curves show a gradual elimination of water between approx. 110 and 400° and above 400°. On the other hand, when the temp. is maintained const. at 400°, most of the water is evolved. Hard clays are notably more unstable. In conclusion a scheme for the dehydration of kaolonite is discussed and the results of x-ray analysis of clays are given (cf. Strutinskii, *C. A.* **21**, 3721). C. C. Davis

Blending of clays. I. R. C. Callister. *Trans. Ceram. Soc.* (Eng.) **27**, 124–49(1928).—With 4 ball clays and 4 china clays 15 blends were made and tested. It was found that by blending clays of known properties the following properties of the mixts. could be closely controlled: air drying linear shrinkage, firing shrinkage from dry at 110° to china glost and biscuit conditions, and loss of wt. during firing. Those properties less closely controlled were modulus of rupture, tensile strength, apparent porosity, absorption, degree of vitrification and color. The modulus of rupture proved a good index to the relative strengths of clays and mixts. Ball and china clay mixts. averaged 10% higher strengths than either clay alone. Mixing fine-grained fat, plastic clays with each other gave low strengths. Fine-grained plastic clays mixed with the larger-grained china clays showed strengths above the expected means. Some of the properties of clays are additive, others only approx. so. H. F. K.

Views on the so-called hygroscopic water of clays. Tsuruji Ozakawa. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* **9**, No. 153, 15–49(1928).—The nature of the hygroscopic water of clays is studied. Intersection points are found on the isotherms which indicate the relation between the quantity of water absorbed and its vapor pressure. O. maintains that the view that water mols are condensed on the surface of clay and that this condensation is only an adsorption is incompatible with the existence of the intersection points. The exptl. results agree with the conclusion that water combines with clay, resulting in the formation of certain hydrates, the compn. of which is ascertained from the intersection points, and that the hydrates form solid solns , the compn. of which varies according to the equil. between the hydrates at various temps. and humidity. A large amt. of exptl. work has been done. L. B. Miller

A new method for testing refractory clays. Albert Granger. Conservatoire National des Arts et Métiers. *Chimie et industrie* Special No., 439(April, 1928).—In testing refractoriness, the smallness of the test pyramids makes it difficult to detect the exact softening point. With some clays a test crucible was found to show signs of softening before the pyramid made from the same clay, while with others there was no noticeable difference. A. Papineau-Couture

The tables of properties of clays and kaolins. Use of the tables for the stoneware clays of the Westerwald region. Fritz Buss. *Keram. Rundschau.* **36**, 219–21(1928).—B. criticizes tables of properties of German clays because the measurement of the properties listed requires elaborate and costly lab. app. A method of classifying different clays from the same deposit or from different deposits is suggested based on the screen analysis, the burning shrinkage and the color after burning. Samples after drying at 110° are crushed in a mortar to a size of about 2 mm., placed in water for several hrs. and screened as a slip through a 4900/cc. screen. The residue on this screen is dried and weighed. A sample of the same material is burned to cone 10 and the shrinkage detd. Clays from the same deposits may thereafter be identified by their similar screen analyses. H. Insley

The dehydration of kaolin. H. A. J. Pieters. Techn. Hoogeschool, Delft. *Thesis* **1928**, 148 pp.—A review with 334 references is given of the literature on kaolin, its constitution, dehydration, rehydration, etc. P.'s work consisted of dehydration and rehydration expts., including static detn. of the soln. pressure of kaolin, the action of HCl and Na_2CO_3 on kaolin and related substances and attempts to synthesize kaolin. The material used was mainly Zettlitz kaolin; other samples analyzed were from Passau and from N. Carolina. For the analysis the KOH method after ignition was found best; HCl decomposes incompletely. Only up to 15.9% of the total alumina dissolves in 2*N* HCl during 6 hrs. on a water bath; nothing in 2*N* Na_2CO_3 soln. The d. was 2.64; after ignition at 700° 2.47; at 1100° 2.67. Kaolin, $Al(OH)_3$ and SiO_2 were found to be hygroscopic; ignited kaolin (metakaolin) was slightly hygroscopic and ignited $Al(OH)_3$ was considerably more so. For the thermal analysis the kaolin was heated in an elec. furnace (10° per min.). Three heat effects were observed: at 100° by moisture escape, at 600° by dehydration, at 950° by exothermic decompn. Kaolin was progressively dehydrated in a nichrome furnace. Air satd. with water vapor at different temps.

was passed over the substance and the temp. detd. for each H_2O pressure at which the kaolin lost wt. From the practically vertical center parts of the dissocn. isobars, (S curves) on which t is largely independent of x, the following values for a p-t curve (dynamical method) were found: p = 17 mm. at 430°, 149 mm. at 475°, 355 mm. at 505°, 760 mm. at 540°. Passau and N. Carolina kaolin gave identical results; at 540° the dehydration is complete. At 17 mm. H_2O pressure 0.7% water was lost at 420° (4 hrs.), 11.6% at 470° (3 hrs.) (90% of total); below 400° 0.4 to 0.6% water escapes. From the data on the quasi monovariable equil. a heat effect of dehydration of 300 cals. per g. kaolin was calcd. Further expts. were made to find the limit of dehydration at p_{H_2O} const. (17.5, 149 and 760 mm.) for different temps., also at 3.6 atm. pressure. Dehydration of more than 13% was obtained for p_{H_2O} = 0 at 470°, for p_{H_2O} = 17 mm. at 490°, for p_{H_2O} = 149 mm. at 510°, for p_{H_2O} = 760 mm. at 580°, for p_{H_2O} = 3.6 atm. at 640°. Dehydration of pholerite is considerably slower: the corresponding values are 510°, 510° and 560° for the first three p_{H_2O}. The grain size (0.5 to 2μ) is not believed to be of great influence. The dehydration follows in general the rules for a solid soln. of water content x. Between about 3 and 13% water the equil. is apparently univariant. Metakaolin (dehydrated kaolin) does not absorb any water at suitable temps. below 700° for p = 149 at 760 mm.; little water was taken up after previous evacuation of the substance. In a nickel-steel autoclave Al_2O_3 ignited at 950° takes up 16 to 17% H_2O, forming a monohydrate at water pressures of 125 and 150 atm. (temp. about 300°); ignition of the oxide above 1100° destroys this absorptive ability. Amorphous SiO_2 (from water glass) takes up 2.7 to 45.7% H_2O at 80 to 130°. Ignited Zettlitz kaolin absorbs up to 14.7% water at pressures of 50 to 130 atm. (2 to 3 days) depending on the previous ignition temp. Up to 550° ignition temp. 14.5%, for 600° to 850° 13.0%, for 900° 12.5%, for 1000° 11.0%, for 1050° 3.0% and 1.6 down to 1.0% for 1100° to 1500° (2 days rehydration, p_{H_2O} between 80 and 120 atm.). A mixt. of Al_2O_3 + 2 SiO_2 takes up only 10.5% water at 100 atm., 2 days; metakaolin under the same circumstances takes up 12 to 13%. Sillimanite takes up 0.7 to 1.3% H_2O at 85 atm., 2 days, nothing after ignition at 1000°. It seems likely that ignition of kaolin over 1100° gives sillimanite + cryst. SiO_2. Static detns. of the soln. pressure of kaolin and pholerite were made in an elec. furnace with a Hg manometer, the tube being evacuated at const. vol. The water yielded was weighed in a $CaCl_2$ tube, after initial evacuation at 400°. For a H_2O loss of 3.4 to 11.5% the p-t curve so detd. agreed well with the dynamic values. The pholerite curve although more retarded by slow decompn. also agrees with the dynamic one and with that of kaolin. Action of Na_2CO_3 on metakaolin indicates that it contains neither free SiO_2 nor Al_2O_3; ignition above 900° only gives a slight soda soly. The Al_2O_3 from metakaolin dissolves almost completely in HCl if the ignition temp. is below 900°; from there on it is very small (Al_2O_3 soly. itself decreases more slowly). Hydrated metakaolin is insol. in HCl, and has a dehydration characteristic like kaolin, yielding its water a little more readily. It is concluded that metakaolin (product between 600° and 900°) is most likely a kaolin anhydride, $Al_2O_3.2SiO_2$. Attempts to synthesize kaolin failed. B. J. C. van der Hoeven

Effect of heat on the crystalline break-up of kaolin. J. F. Hyslop and H. P. Rooksby. *Trans. Ceram. Soc.* (Eng.) **27**, 93–6(1928).—An x-ray investigation of kaolin after heat treatment showed a breakdown at 550° to an α form which is stable to 870°, the occurrence of a β form between 870 and 1000°, after which only mullite and SiO_2 remain. The α- and β-patterns have not been identified. H. F. K.

Fused quartz. Felix Singer. *Sprechsaal* **61**, 221–2(1928).—Discussion on the prepn. and properties of fused quartz and how it differs from ordinary quartz. Comparisons of such properties as compressive strength, elasticity, dielectric strength, etc., are made with other ceramic materials. R. A. Heindl

The development of the shale planer. C. Forrest Tefft. *J. Am. Ceram. Soc.* **11**, 785–90(1928). C. H. Kerr

Vaccum treatment of clay slips and bodies. H. M. Kraner and A. H. Fessler. *J. Am. Ceram. Soc.* **11**, 725–9(1928).—Since there is only 1.0–1.3% air by vol. in clay slips, the increase in d. due to removal of air must be slight. The dielectric strength of the porcelain body was not increased by vacuum treatment of the slip or body, and there was no noticeable improvement in mech. strength. C. H. Kerr

Formulas for slip calculations. S. R. Hind. *Trans. Ceram. Soc.* (Eng.) **25**, 108–10(1926).—A collection of formulas is given for use in calcns. in connection with slips of clays, various ground materials, and mixts. B. C. A.

The effect of the burning on the unit weight and specific gravity of brick. CHR. K. VISSER. Hochschule Delft. *Intern. Congress Testing Materials* **1927**, II, 321-37.— F. O. A.

White efflorescences appearing on bricks and tiles (during baking). K. ZIMMERMANN. *Klei* **19**, 1-8, 79-80(1927); *Chimie et industrie* **20**, 284-5(1928).—A discussion of the causes of their formation and of the methods of preventing them. A. P.-C.

The pores in brick. G. J. EASTER. *J. Am. Ceram. Soc.* **11**, 764-8(1928).—The resistance to the flow of air through the sample is measured and the pores are arbitrarily considered to be replaced by an equiv. vol. of parallel cylindrical capillaries. The dimensions of these capillaries are then computed. The method is applicable only to bodies having open pores. C. H. KERR

Some common abuses of fire brick. L. S. LONGENECKER. *Blast Furnace Steel Plant* **16**, 809-11(1928).—Two features in furnace construction that involve unduly severe service, irregular joints and the keyed arch roof are discussed. Thinner and better joints can be secured by installing with care brick of uniform thickness and good workmanship. In a keyed sprung arch, brought up to working temp., the entire load is concd. on the semi-soft inner brick ends, because of the difference of thermal expansion of the inner and outer brick ends. A radial furnace arch supported overhead which automatically allows for expansion and contraction and eliminates the skew backs is described. J. W. BOECK

The thermal expansion of fireclay bricks. ALBERT E. R. WESTMAN. Univ. Ill. Eng. Expt. Sta., *Bull.* **181**, 27(1928).—In scope this work covers the detn. of the expansion behavior of 20 brands of fireclay brick of wide range of qualities through temps. from 25° to 900°. The app. used was a rigid water-cooled metal framework within which was placed the electrically heated specimen supported by fused silica end pieces which in turn transmitted the expansion pressure to a dial gage. A multiple base-metal thermocouple with three hot junctions was used to measure temps. In nearly all cases studied the data obtained from these thermal expansion measurements, from petrographic examn. by the powder immersion method and from chem. analysis were in reasonable quant. agreement with the assumption that the lower inflections of the thermal expansion curves were due to the inversion of cristobalite and the upper inflections to the inversion of quartz, these substances being originally present in the raw materials as uncombined silica. It is believed, therefore, that with more accurate methods for detg. percentage expansions due to inversions and more reliable factors for calculating percentages of cristobalite and quartz from such data, useful analyses of fireclay bricks could be made. H. L. OLIN

A laboratory furnace for testing resistance of firebrick to slag erosion. RALPH K. HURSH AND CHESTER E. GRIGSBY. Univ. Ill. Eng. Expt. Sta., *Circ.* **17**, 18(1928).—A cylindrical furnace chamber is supported vertically on rollers and is rotated about its axis during the test. It is heated to any desired temp. with controlled atm. conditions with a blast burner using city gas and air at high pressure. Powd. slag is fed at uniform rate through the burner and blown with the blast onto the vertical faces of standard-sized test bricks which line the chamber, each brick being brought repeatedly and successively into position before the burner and thereby subjected to uniform treatment. H. L. OLIN

Silica brick in the open-hearth furnace. B. M. LARSEN. U. S. Bureau of Mines. *Blast Furnace Steel Plant* **16**, 803-7(1928).—Silica brick, though far from being a perfect refractory, is admirably adapted for arches and supporting loads at temps. close to the m. p., also recrystg. to form an unbroken inner surface covered with a glaze that reflects the radiant heat. Solid silica exists in 4 forms: The crystal forms, tridymite, is stable from 1600 to 2680° F. and cristobalite is stable from 2680 to 3110° F. Cristobalite m. 3110° F. and can be easily supercooled, giving the various forms of quartz glass, nitrosil, etc. The presence of fluxing impurities, which will dissolve silica, tends to hasten the changes, which normally are very slow. Each cryst. form has an α- and β-form stable at low and high temps., resp. The α and β inversions are rapid and reversible. The important change in burning silica brick is the partial recrystn. of the original quartz to form cristobalite and tridymite. The new crystals interlock and grow together in a structure well adapted to resist deformation by external stress, even at high temps. During burning the bricks expand 10 to 11% by vol. because of the partial change from quartz to cristobalite and tridymite. Any portion of the brick which subsequently in service changes from cristobalite to tridymite may undergo an addnl. permanent expansion from 5 to 6%. This is the principal cause of permanent expansion of arches in service. New silica brick composed chiefly of cristobalite expand about 3.5% over a small temp. range, which is perhaps the principal

cause for cracking from rapid heating or cooling at low temps. Al_2O_3 and the alkalies are more dangerous fluxes than most of the other oxides, so mortars contg. clay or Na silicate should not be used in laying up or washing surfaces. The changes occurring in the silica brick in the open-hearth roof arch are given in detail. Fluxing and fusing are the 2 distinct modes of failure in the silica roof. Below 2975° F. only slow wearing away by fluxing occurs. Above this temp. fusion of the hot end of the brick occurs. Definite currents of hot gases may sweep up and impinge on localized areas of the roof, causing overheating and overfluxing. Their control is a matter of furnace design and operation. The causes of spalling and the seasoning of roof brick by flux satn. and recrystn. are discussed. J. W. Boeck

Constitution of silica bricks. K. Endell and E. Pfeiffer. *Ber.* No. 91, *Werkstoffausschusses Ver. deut. Eisenhüttenleute, Sitzb.* **2,** 8(1926); *Physik. Ber.* **8,** 78.—The vol.-temp. diagram of the SiO_2 system is constructed by means of data from the literature. Examn. is made of 41 different bricks, whose customary phys. properties are recorded. Good grades of bricks show an elongation of 0.7–0.8% up to 300°, 0.9% at 600° and 1.0% at 800°. Poor grades give 0.4% at 300°, then a strong elongation between 500° and 600°. After heating at 1450°, a good brick does not retain any permanent deformation, whereas a poor-grade brick remains 0.6 to 0.8% deformed Since the main deformation of good bricks occurs below 300°, the heating of coke ovens should be carefully controlled up to that temp. A. L. Henne

Studies on drying. First experimental results. V. Bodin and P. Gaillard. *Ceramique* **30,** 205–17; *Chem. Zentr.* **1927,** II, 1504.—In a tube equipped with measuring instruments the test sample of clay is dried under known conditions. The conditions for drying a marl, a brick clay and a fireclay were detd. J. S. Reichert

Tunnel kilns for burning firebricks. I. S. R. Hind. *Trans. Ceram. Soc.* (England) **25,** 154–70(1926).—The relative merits of tunnel kilns and other continuous kilns for burning firebricks are discussed. The special requirements and the chief features of design of such tunnel kilns are also outlined. B. C. A.

Continuous and periodic electric decorating kilns. R. J. Eves. *J. Am. Ceram. Soc.* **11,** 753–8(1928). C. H. Kerr

A method of testing the probable durability of tank blocks. E. J. C. Bournaker. *Pottery Gazette* **53,** No. 610, VI–VIII(1928).—In a qual. test a chip of the tank block is treated with a 2:1 HF-H_2SO_4 acid mixt. in a Pt crucible and evapd. in a sand bath, after which it is boiled in a 1:1 H_2SO_4 water mixt. After drying at 110° it is examd. for cryst. appearance. A good block should show cryst. appearance markedly. The grog should be held firmly in place by the cryst. matrix of sillimanite and there should be no shedding of the grog during boiling. A poor block shows no cryst. formation. The chip will have a ragged look due to soln. of the bond. In the quant. test a weighed sample cut as near $^1/_2'' \times {}^1/_2'' \times 1''$ as possible, with beveled edges, is treated with 3:2 HF-H_2SO_4 mixt. and heated at 100° for 3 hrs. A detailed description of a lead distn. tank is given. Soly. of 5 blocks was 18.9–5.98%, the lowest soly. indicating the block with the longest service record. R. A. Heindl

Porcelain as an industrial material. H. Handrek. *Keram. Rundschau* **36,** 363–5, 386–8, 410–2, 429–31(1928); cf. *C. A.* **22,** 2039.—Curves showing the effect of suitable and unsuitable glazes on modulus of elasticity, bending strength, tensile strength and impact bending resistance of porcelain are given. Av. values are given for 30 different phys. properties of glazed and unglazed porcelain. Methods of measuring these properties are described. Curves are reproduced which show decrease in tensile strength, compressive strength, bending strength and torsion strength with increase in cross-section of the porcelain and also curves which show the relation of break-down resistance and puncture voltage to temp. H. Insley

The preparation of liquid bright and burnished gold. F. Chemnitius. *Sprechsaal* **60,** 182–4(1927); cf. *C. A.* **22,** 3751.—The complicated constitution of these prepns. in the form of terpenes is discussed. Liquid bright gold is applied to the ware and fired. It results without further effort in a bright shiny gold. The burnished gold is applied as an oxide (in suspension) which after firing must be polished in order to obtain the proper finish. A complete description of procedures to follow in the small-scale prepn. of the two materials is included. Each step leading to the prepn. of the compds. is clearly stated. R. A. Heindl

The history of ceramics. III. The manufacture of porcelain in Italy before the

discovery of hard porcelain in Europe. C. F. BONONI. *Giorn. bibliografia tec. intern.* **4,** 573–88(1928); cf. *C. A.* **22,** 2251. C. C. DAVIS

Colors in ceramics. E. W. ELY. *Bull. Am. Ceram. Soc.* **7,** 311–3(1928).—Some simplification and standardization are recommended. C. H. KERR

Firing ceramic ware with gas. H. L. READ. *J. Am. Ceram. Soc.* **11,** 759–63 (1928). C. H. KERR

The application of liquid fuels in ceramic industry. A. POPOFF. *Sprechsaal* **61,** 195–7(1928).—The advantages of firing ceramic ware in tunnel kilns and intermittent round kilns with fuel oil as against coal or wood are given. Charts are included showing regularity of oil firing against wood firing as found in specific installations. Temps. used and compns. of bodies and glazes manufd. are given. R. A. HEINDL

Calculations derived from [ceramic] industrial practice. PAUL POTTIG. *Sprechsaal* **61,** 215–9(1928).—Drawings show how the raw materials entering into ceramic manuf. as well as the finished product can be diagrammatically kept both by wt. and percentage of materials. Exact knowledge of costs of all raw materials, finished products, overhead and defective ware can be kept by these records. R. A. HEINDL

Proposals for unified tests of ceramic materials. O. KALLAUNER. *Intern. Congress Testing Materials* **1927,** II, 338–58.—Proposals made were: (*a*) A rapid detn. of the harmful effect of lime nodules in burned brick ware. Five specimens are placed in a covered vessel on a support above water which is brought to boiling in 1 hr., and allowed to boil another hr. After 4 hrs. the specimens should be free from defects due to lime nodules. (*b*) Testing roof tile for impermeability to rain. A pair of 3-course tiles is surrounded by sheet iron cemented with litharge and glycerol, and water falls under specified conditions. The tile should remain dry on the under side for 24 hrs. (*c*) An exclusively volumetric detn. of the absorption of ceramic specimens. Detd. on a vol. instead of on a wt. basis, the absorption is expressed more significantly. (*d*) The detn. of sol. salts in ceramic clays. The methods of the Tonindustrie Lab. in Berlin are recommended. (*e*) The detn. of sol. salts in ceramic products should be carried out by similar methods. (*f*) Testing the acid resistance of ceramic products by treating 1 g. with 1.84 H_2SO_4, boiling 30 min., cooling, dilg., adding NaOH and weighing the residue, after drying at 120°. Tests for roof tile should include permeability, absorption, frost resistance, flexure and impact resistance. F. O. A.

Report of Committe C-8 on refractories. G. A. BOLE, *et al.* *Trans. Am. Soc. Testing Materials* **1928** (preprint), No. 51, 7pp.—The report includes definitions on various clays, recommended changes in the ° C. values of certain pyrometric cones, a comparison of long-time and short-time reheat tests on the basis of vol. change, the pyrometric cone equivalents of 8 refractory cements, and a discussion of the sand-blast method of measuring the resistance of refractories to abrasion at high temps. The need of an improved method of analysis of high Al refractories is stated but no recommendation is made. H. F. K.

Kaolinic refractories and their properties. MARK J. TERMAN. Babcock and Wilcox Co., Pittsburgh. *Blast Furnace & Steel Plant* **16,** 814–5(1928).—Kaolinic material is processed by a new method, which develops its refractory qualities to the fullest extent and produces a recrystd. refractory with a max. uniformity of quality and size. The properties and application of this special refractory are described. J. W. B.

The effect of firing on the chemical and physical properties of refractories. W. MIEHR, J. KRATZERT AND H. IMMKE. Centrallab. und Forschung Inst. des Didier Concerne. *Tonind. Ztg.* **52,** 280–2, 298–301, 323–5(1928).—The chem. and mineralogical properties of refractories were detd. with special reference to the formation of mullite between 1000 and 16,000°. The effects of firing temps., time of firing, size of grain, clay content and alkalies on the formation of mullite were studied by means of the petrographic microscope and x-ray. Crucibles made of mullite were found to be

most resistant to slag action, being much better than alundum crucibles in this respect. It was also found that the firing temp. has an important bearing on the thermal expansion of siliceous clays. One siliceous clay when fired to cone 10 had a very irregular expansion curve due to the rapid vol. changes of different forms of SiO_2 at different temps. By firing this same clay to cone 20 its expansion curve became smooth and much lower than that obtained on the clay fired to lower temps. H. G. SCHURECHT

Method and apparatus for determining the conductivity of refractory materials. GEORGES MEKER. *Céramique* **30,** 445–52; *Chem. Zentr.* **1927,** II, 2000.—A rod 20–40 cm. long, and 5.5 cm. high and wide, is heated at the front side with a Meker burner, and the temps. are taken at the front and several places along the rod. The curves obtained are a relative and technically useful, though not an abs., measure of the thermal cond. G. SCHWOCH

Abrasives. V. L. EARDLEY-WILMOT. *Mineral Ind.* **36,** 1–10(1927).—The various abrasives, natural and artificial, are discussed and statistics given. A. B.

Use of hydrochloric acid for testing acid-resisting enamel. A. MALINOVSZKY. *Bull. Am. Ceram. Soc.* **7,** 313(1928); cf. *C. A.* **22,** 1023.—Cast iron sanitary ware must resist HCl. C. H. KERR

Basic open-hearth practice (WATERHOUSE) **9.** Magnesite (HENTON) **18.** The influence of H-ion concentration and electrolytes upon the turbidity, sensitivity and settling rates of certain pleistocene clays (GRAHAM, PEARCE) **2.** Migration of ions from aqueous solutions into glass (QUITTNER) **2.** The relation between coagulation, electrokinetic migration velocity, ionic hydration and chemical influences—an experimental study of clay, quartz and permutite suspensions (TUORILA) **2.** The system: aluminum oxide–silicon oxide (EITEL) **8.**

KUHLEIN, THEO: **Optisches Glas. Unzerbrechl. Glas. Altern. d. Glases.** LEIPZIG: Verslag f. Kunst und Wissenschaft. 63 pp. M. —.40.

Adressbuch der Email-Industrie. REDAKTION DES SPRECHSAAL. Cobourg: Müller and Schmidt. 284 pp.; 6.50 marks. Reviewed in *Chimie et industrie* **20,** 597 (1928).

Glass. SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE ST.-GOBAIN, CHAUNY, ET CIREY. Brit. 284,648, Feb. 2, 1927. A glass to be used for x-ray screens contains PbO 45 and BaO 17% or other suitable proportions of oxides of Pb and Ba detd. by the formula $B \times 1.005^{(P + 350)} = 110$, in which B indicates the content of BaO and P the content of PbO.

Sheet glass. ENOCH T. FERNGREN (to Libbey-Owens Sheet Glass Co.). U. S. 1,684,437–8, Sept. 18. Mech. features.

Sheet glass apparatus. FRANK FRASER (to Libbey-Owens Sheet Glass Co.). U. S. 1,684,440, Sept. 18.

Glass furnace construction. THOMAS B. HART (one-half to Adamston Flat Glass Co.). U. S. 1,685,053, Sept. 18.

Apparatus for feeding mold charges of molten glass. SAMUEL G. STUCKEY. U. S. 1,686,109, Oct. 2.

Apparatus for delivering charges of molten glass. LEONARD D. SOUBIER (to The Owens Bottle Co.). U. S. 1,685,143, Sept. 25.

Drawing sheets or plates of glass. FRITZ ALTHOF. Fr. 635,934, June 13, 1927. An app. is described for drawing plates of glass comprising a metal mouthpiece with a slit opening mounted interchangeably in a body floating on the refractory material.

Glass rings. MILOS KLAVIK. Austrian 108,955, Oct. 15, 1927. A mold is described for making tubular glass bodies and subdividing them into rings.

Apparatus for finishing and annealing lamp bulbs or other blown glass articles. JAMES BAILEY (to Corning Glass Works). U. S. 1,685,349, Sept. 25.

Apparatus (with temperature control device) for annealing glass articles. JAMES BAILEY (to Corning Glass Works). U. S. 1,685,348, Sept. 25.

Metallic coating on glass. MAX ALBRECHT. Fr. 635,813, Sept. 20, 1926. An oscillating basin is described which contains a bath in which the objects to be coated are placed.

Liquid preparations of gold and platinum. P. P. BUDNIKOV. Russ. 3433, Aug. 31, 1927. Reaction products of P-S compds., or Cl-P-S compds. or Ni sulfide or a mixt.

of the above compds. with S-Cl compds. or alkali polysulfides are mixed with Au or Pt salts and are used for hot plating of ceramic or glass ware.

Apparatus for drying clay products, etc. EUGENE A. HULTS. U. S. 1,685,026, Sept. 18.

Magnesite brick. BERRY M. O'HARRA and EDGAR A. SLAGLE (to American Smelting & Refining Co.). U. S. 1,686,876, Oct. 9. Small particles of crushed calcined magnesite are mixed with water contg. $MgCl_2$ in quantity of 5–10% that of the calcined magnesite, and to this mixt. there is added an aq. soln. of NaOH or NH_4OH in quantity approx. equiv. to the $MgCl_2$ so that $Mg(OH)_2$ is formed in contact with the calcined magnesite particles. The material is pressed into bricks, burned to convert the $Mg(OH)_2$ into MgO and the burning is continued at a higher temp. to convert the MgO into periclase.

Furnace for baking porcelain. NGUYEN B. CHINH. Fr. 32,601, Oct. 4, 1926. Addn. to 595,009.

Cleavable plates from ceramic pastes. WILLI HAMPE and MAX RICHTER. Fr. 635,233, May 30, 1927. Plates or the like are provided, at the time of manuf., with a combustible or incombustible but shrinkable layer on the sections of cleavage, so that after baking, the plates can be easily sepd. by a shock.

Abrasive disks. HERBERT R. STRATFORD (to Stratmore Co.). U. S. 1,687,071, Oct. 9. Cloth carrying abrasive material is provided with a backing sheet of vulcanized fiber which, for a section 1 in. wide and 10 mills thick, has a longitudinal tensile strength of over 150 lb. and a transverse tensile strength of over 75 lb.

Abrasive sheets. HERBERT R. STRATFORD (to The Stratmore Co.). U. S. 1,684,748, Sept. 18. A sheet of cellulosic material such as vulcanized fiber is provided with a layer of abrasive grains adhesively secured to one surface of the sheet. Sheet material is used having a tensile strength of not less than 170 lb. per sq. in. in one direction and of not less than 85 lb. per sq. in. in a direction at right angles to the first.

Rubber-bonded abrasive articles. DUANE E. WEBSTER (to Norton Co.). U. S. 1,687,410, Oct. 9. In forming grinding wheels or other abrasive articles, abrasive grains are mixed with rubber latex, vulcanizing agent and an accelerator, coagulation is effected, *e. g.*, by use of Zn acetate, and the coagulated mixt. is then subjected to vulcanization. Cf. *C. A.* **22**, 3273, 3969.

Waterproof sheet abrasive material. CARL A. KLEIN and ROBERT S. BROWN. U. S. 1,687,453, Oct. 9. A base material such as paper or cloth is waterproofed by passing it through a bath of linseed oil contg. a small proportion of paraffin or other suitable wax and maintained at a temp. of 100° or higher; any surplus waterproofing material is removed by heated pressure rollers, an adhesive consisting of a drying oil such as linseed or tung oil and a varnish gum or synthetic resin is then applied, followed by successive applications of abrasive material such as sand and baking after each application of this material (all these operations also being carried out at temps. above 100°). U. S. 1,687,454 specifies a similar preliminary waterproofing followed by application of an adhesive comprising a drying oil and a gum such as dammar or copal and of abrasive material.

Refractory articles of silicon carbide. M. L. HARTMANN (to Carborundum Co., Ltd.). Brit. 284,732, Feb. 4, 1927. Molded articles are made of SiC substantially free from Fe and other easily reducible metals or their compds. The material may be subjected to a preliminary magnetic purification and bonded with pure kaolin 8 and feldspar 2%. Such a mixt. may be moistened with water, molded and fired.

Zircon refractories. LEROY H. MINTON. U. S. 1,684,739, Sept. 18. Zircon is finely ground in the presence of water contg. an org. deflocculent such as tannic acid and the resultant product is shaped and fired.

Tunnel kiln and associated furnace construction. CHARLES F. GEIGER (to Carborundum Co.). U. S. 1,686,083, Oct. 2. A furnace and kiln construction is specified which is suitable for burning *ceramic ware,* etc.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

New Dutch cement specifications. ANON. *Zement* **17**, 1105–8(1928). H. F. K.

Italian (cement) specifications. ANON. *Zement* **17**, 1273–4(1928). H. F. K.

Aluminous cement. HENRY LE CHATELIER AND ANDRÉ DUHAMEAUX. *Intern. Congress Testing Materials* **1927**, II, 208–18.—After a review of the chem. constitution

and hydration, the rate of reaction of the cement was followed by observing the absorption of water with time. The speed varies with the temp. It is very slow with a sugar soln. It is assumed that sub-microscopic needles are responsible for the strengths developed. Whereas portland cement or plaster of Paris on exposure to moist air will swell, the alumina cement does not. F. O. A.

The preparation of standard cement samples. ETIENNE RENGADE. *Chimie et industrie* **Special No.,** 424–8(April, 1928).—A discussion of the necessity and difficulty of prepg. standard cement samples, particularly for tensile and compression strength testing, with a brief outline of the chief problems which require discussion and study in this connection. A. PAPINEAU-COUTURE

Measurement and the importance of particle size of cement. DONOVAN WERNER AND STIG GIERTZ-HEDSTRÖM. *Zement* **17,** 1002–5, 1038–42, 1071–6(1928).—A sedimentation app. is described with which the particle size of cements was measured. From the distribution curve and the specific surface of a given cement it was possible to predict quite accurately the compressive strength of the cement at any age, other variables being controlled. The fineness or specific surface had a definite relation to the age at which a cement attains strength. H. F. K.

Chemistry of early-strength cements. HANS KÜHL. *Zement* **17,** 686–91(1928).—Correct compn., thorough mixing, proper burning and grinding are all essentials. The influence of salts such as 2% $CaCl_2$ or the equiv. chloride or nitrate of the alkali and alkaline earth is beneficial, while the salts of the heavier metals are without effect or are injurious. H. F. K.

Early-strength cement and cold water. H. VIERHELLER. *Zement* **17,** 892–4 (1928); cf. *C. A.* **22,** 2041.—The reduction in strength at early ages was much less for aluminous cement than for two others observed at temps. near 0°. H. F. K.

Strength, soundness and shrinkage of cements. W. GEHLER. Materialprüfungsamt, Dresden. *Intern. Congress Testing Materials* **1927,** II, 106–26.—A discussion of the results obtained from the present standard methods and proposals for improvements in specifications so as to improve the probability of securing more concordant results from different labs. on the same cement. F. O. A

Thermal phenomena in the setting of portland cement. P. JOYE. Univ. Fribourg, Switzerland. *Intern. Congress Testing Materials* **1927,** II, 219–30.—The sp. heat of the ground clinker used was 0.199, obtained by suspending in toluene and heating electrically as compared with 0.199 and 0.195 obtained by calcg. The set cement (25% H_2O) in the solid had sp. heat 0.332 and in the powder 0.334. On heating to const. wt. at 110–5° the cement lost 9.9% of its wt. and the sp. heat was 0.244. A concrete dam of about 350 cu. m. reached a max. temp. rise of about 25° in 2 weeks and then cooled down very slowly. The total heat evolved was at least 48 cal. per kg. cement, but in the lab. all values were below 40 cal. The heat evolved varies with the initial temp. It seemed to be greater in the presence of diatomaceous earth than in its absence. F. O. A.

Determination of free lime in cinders and cements. E. DIEPSCHLAG AND A. MATTING. *Zentr. Hütten- u. Walzwerke* **31,** 363–6, 377–80, 394–8; *Chem. Zentr.* **1927,** II, 1194.—The authors discuss first the occurrence of free CaO in cinders and cements and then give a crit. description of the various methods in use for detg. it Their own expts. involved its detn. by means of H_2O contg. CO_2, pure H_2O, microscopical examn. and titration with $AcONH_4$. Microscopical examn. in polarized light is useful for qual. purposes; for quant. purposes only titration with $AcONH_4$ is of use. G. SCHWOCH

The mechanism of the chemical disintegration of cements. HENRI LAFUMA. *Chimie et industrie* Special No., 431–3(April, 1928); cf. *C. A.* **22,** 150.—From a discussion of the mechanism of the action of $CaSO_4$ and of sea water on portland and aluminous cements, L. concludes that this phenomenon is similar to the hydration of anhyd. compds.; when the reaction takes place directly with the solid constituents of the cement (as is the case with portland cement), internal stresses are set up (due to expansion) which may be sufficient to disrupt the mortar or to disintegrate it more or less rapidly; if, on the other hand, the reaction takes place only after the constituents have been dissolved in water (as is the case with aluminous cements) there is no expansion, and the crystn. of the reaction products may even increase the strength of the mortar. Slag cements apparently contradict this theory, as they seem to fix CaO without previous soln. of its constituents. A. PAPINEAU-COUTURE

Some sources of error in the determination of the loss on ignition of cements. G. BAIRE. Soc. des Ciments Français. *Chimie et industrie* **Special No.,** 429–30(April, 1928); cf. *C. A.* **20,** 488.—Results of tests are given to show that when coal is ignited

simultaneously in the same muffle as cements the loss on ignition of the latter is increased by reduction of SO_3 and probably also by partial reduction of Fe_2O_3 to FeO.
A. PAPINEAU-COUTURE

Report of the kiln commission of the Society of German Portland Cement Manufacturers. E. SCHOTT. *Zement* **17,** 1198–1201(1928). H. F. K.

Waste heat in portland cement manufacture. HENRY POOLEY. *Engineering* **125,** 497–8, 562–3(1928).—A discussion of the effect of waste heat boilers, spray feed and filtration of slurry, and long kilns on heat economy. RAYMOND WILSON

Crystal forms in technical portland cement clinker. III. A. GUTTMANN AND F. GILLE. *Zement* **17,** 618–9(1928); cf. *C. A.* **22,** 3273.—A newly observed, weakly refracting form is described. The optical consts. are α 1.55, γ 1.56. The name epezite is suggested. H. F. K.

Action of sulfates on the components of portland cement. T. THORVALDSON, V. A. VIGFUSSON AND R. K. LARMOUR *Trans. Roy. Soc. Canada* [3], **21,** Sect. III, 295–310(1927); cf. *C. A.* **20,** 2400–1; **22,** 2649.—Mortar bars $^1/_8 \times {}^5/_8 \times 7^1/_2$ in. were made from the above pure substances and standard Ottawa sand, distd. water being used for gaging. A mix. of 1 of the ingredients to 5 of sand was used in the earlier expts. and later a mix of 1 to 7.5. After curing the bars were placed in the sulfate soln. and the expansion of the bars was measured from time to time over a period of 2 years. The results showed that solns. of Na_2SO_4 react on but one of the components of portland cement, tricalcium aluminate, while disintegration in solns. of $MgSO_4$ is the result of the sulfate action on all 3 constituents. The reaction, however, is more rapid with the tricalcium aluminate. Mortars made from tricalcium silicate and from dicalcium silicate to which tricalcium aluminate was added disintegrated rapidly in solns. of both Na_2SO_4 and $MgSO_4$. Mortars made from a composite of the 3 major constituents of portland cement had the usual strength of similar mortars made from a normal portland cement and in relation to the action of Na_2SO_4, $MgSO_4$ and $CaSO_4$ solns. behaved like the normal cement. Steam treatment of the various mortars increased the resistance against sulfate action enormously. The action of the steam is apparently chem., since it affects lean and rich mortars to about the same extent. J. W. SHIPLEY

Development of cracks in glass plates used in making cement pats. F. SCHOTT. *Zement* **17,** 1134–7, 1169–72(1928).—Pats adhere to the glass plates more frequently after water curing than after air curing. Unsound pats air-cured adhered only about a day but during that time cracks developed. On slightly roughened glass surfaces the phenomenon occurs more surely. A cryst. growth found to be $Ca(OH)_2$ is responsible for the destructive action. The fineness of the cement used is apparently without influence on this tendency to adhere. H. F. K.

Burning processes in the shaftkiln. HANS KÜHL. *Zement* **17,** 859–62(1928).—Cylinders of powd. coke and coal mixed with raw materials for cement were heated to det. the temp. and time required to consume the C. No appreciable effect on the C was noted in one-half hour heating periods at temps. below 900°. The consumption of C depended much more on temp. than on fineness of particles. H. F. K.

New cement-burning process in the high duty shaftkiln. "System Andreas." KARL BIEHL. *Zement* **17,** 970–3(1928).—See *C. A.* **22,** 4219. H. F. K.

Heat balance in rotary cement kilns. HENRY POOLEY. *Engineering* **126,** 219–20 (1928). RAYMOND WILSON

An American pozzolana and its effect on portland cement concrete. E. LEE HEIDENREICH. *Rock Products* **31,** No. 20, 39–44(1928).—A discussion of the use of pumicite as an admixt. and replacement for cement in concrete. RAYMOND WILSON

Volumetric changes in portland cement mortars and concretes due to changes other than variables in temperature. RAYMOND E. DAVIS. Univ. of Cal. *Intern. Congress Testing Materials* **1927,** II, 145–66.—A progress report. Mortar bars shrink in air about 0.15% to a const. in about 1 year, the shrinkage being independent of the amt. of lime used (max. lime 1:1). Brick piers in air expanded at first and then shrank. Lime seems to promote the swelling when the humidity is high. When the mortar is cast in a nonabsorbent mold it does not behave as it does when used in brickwork. Numerous expts. have been made on vol. and wt. changes in granite concrete under a variety of conditions yielding numerous conclusions too detailed and varied for abstracting. F. O. A.

German concrete products industry. F. HOFFMANN. *Zement* **17,** 630–5(1928).—Some types of machinery and methods used in the concrete block and tile manuf. are illustrated and discussed. H. F. K.

A contribution to the study of concrete. G. MAGNEL. Univ. Gand. *Intern. Congress Testing Materials* **1927,** II, 139–44.—$CaCl_2$ improved the strengths at 3, 7

and 28 days of 3 slag cements and hurt those of one. Deviation from Abrams water-cement ratio law was noted when making concrete from crushed porphyry and powder of the same as fine aggregate, possibly due to a pozzolanic action. Preliminary results on resistance of concrete to impact indicate that a slump of 5 cm. gives better results than a slump of 1 cm., in spite of the fact that the strength to compression goes the other way. Crushed stone gives better results than gravel. The correlation between impact and compression resistance is poor. F. O. A.

Contraction and expansion of concrete. Experimental results. H. Rabozee. École militaire, Brussels. *Intern. Congress Testing Materials* **1927**, II, 167–71.—Variations in lengths are caused by chem. changes during setting and hardening, changes in temp. and in humidity. The chief changes are due to the latter, being 0.036% in an aluminous cement, 0.045 in an early strength portland and 0.076 in a slag cement concrete. Age did not seem to affect the intensity of the phenomena. F. O. A.

Mortar and concrete. E. Probst. *Zement* **17**, 899–905, 943–5(1928).—Concrete specimens carrying 33–85% sand decreased in resistance to wear and increased in absorption with the higher sanded mixes. Lean mortar and concrete mixes were less affected by 12 months' action of $MgSO_4$ solns. where the test pieces were faced with a rich mortar, indicating the effect of porosity on the resistance to destructive solns. H. F. K.

Design of concrete mixtures. R. W. Crum. Iowa Highway Commission. *Intern. Congress Testing Materials* **1927**, II, 32–60.—Either the water-cement ratio or void-cement ratio is very useful in designing concrete mixts., but the preliminary work should be done with materials to be used in the field and under conditions as close to those of the application as possible. Methods of putting the water-cement ratio control into practice are discussed. F. O. A.

The adjustability of early-strength concrete in tension and compression specimens. Bernhard Möhlmann. *Zement* **17**, 390–9, 581–7, 619–23, 658–60, 691–6, 1137–40 (1928).—The equipment used in this investigation consisted of a 500-ton compression, a 50-ton transverse, a 3-ton tensile machine and Martens mirror app. for measuring the changes in length of the specimens under load or tension. The age, kind of cement, consistency of batch, type of aggregate, mix, curing and size of test pieces were the factors considered in relation to the ability of concrete to adjust itself under test. The modulus of elasticity (E) was found to increase with age of specimen and to be greater for the early strength cements than with normal portland cements. Factors decreasing the value of E are increased H_2O content, increased size of specimen, and increasing span. Gravel graded small and having a high voidage also decreases the modulus. For like dimensions E for compression is greater than for tension. With increasing strength the ratio of compression E to tension E decreases. In general the factors increasing the strength of concrete also increase E. H. F. K.

Effect of the length of the mixing period on the quality of the concrete mixed in standard pavers. J. L. Harrison. *Public Roads* **9**, 93–111(1928).—Comprehensive field tests were made on the compressive strength of samples of concrete taken after varying mixing periods. The results indicate that concrete is not improved by mixing for greater lengths of time than 45 secs. L. B. Miller

Graphic method of calculating the raw meal. R. Grün and G. Kunze. *Zement* **17**, 1166–9, 1201–4(1928).—The use of the right-angled triaxial compn. diagram is discussed. With it comes a clearer understanding of the compn. of the resulting cement and its nearness to the unsound limits, of the possible change in CaO content, of the contents of the several constituent minerals, and of the relation between the compn. and the strength characteristics of the product. H. F. K.

Geseke chalk formation and its use in the manufacture of natural cement. Haegermann. *Zement* **17**, 856–8, 894–8(1928).—Because of the non-uniformity in the deposit, even within a stratum, and the excessive Ca present, the material does not burn to a good cement. The product made therefrom is a weakly sintered marl and the blast furnace slag mixed. H. F. K.

Shrinkage effect of Celite in mortar and concrete. A. S. Levens. Univ. of Minnesota. *Eng. News-Record* **101**, 507–8(1928).—Results are given of tests made to det. the effect of Celite on shrinkage of mortar and concrete. *Conclusions.*—(1) The shrinkage of 1:3 mortar is increased 10–25% when Celite is added in amts. greater than 2%. (2) The shrinkage of 1:1½:3 and 1:2:4 concretes is not materially affected by incorporation of 2 and 3% of Celite, resp. (3) The shrinkage of 1:3:6 concrete is increased 40% when 5% Celite is added. R. E. Thompson

Some attempts to steam cure test pieces to attain twenty-eight-day strengths in two days. Karl Biehl. *Zement* **17**, 654–7(1928).—A 50-l. autoclave capable of 50

atm. pressure was used in this work. Twelve cements were used in making test pieces to be steamed. Approx. 28-day values resulted from 8 hrs. steaming at 16 atm. (200°). The strength found increases generally with increased temp. and time until a max. is reached beyond which the values fall. H. F. K.

Disintegration of concrete due to magnesia cement. H. RICHARZ. *Tonind.-Ztg.* **52,** 1593–4(1928).—About 6 months after replacing the surface of a magnesia cement floor with portland cement mortar the latter began to disintegrate; the explanation was given as being due to the magnesia in the base. F. O. A.

Protection of concrete by chemical means. C. R. PLATZMANN. *Chem.-Ztg.* **52,** 657–8(1928).—Impregnation of the concrete surface with a fluosilicate soln. affords some protection against weak acids and other destructive solns. R. W.

Poured concrete columns with circular reinforcement. R. SELIGER. Hochschule, Wien. *Beton Eisen* **27,** 329–35(1928). F. O. ANDEREGG

Examination of reinforced concrete structures near the sea in the Dutch East Indies. C. WOLTERBEEK. Rijkswaterstaat, Zutphen. *Intern. Congress Testing Materials* **1927,** II, 172–83.—Trouble has occurred especially above high-water mark because of the rusting of reinforcing rods where the concrete was not sufficiently dense or protected. Repairs were made by chipping out the poor concrete and cleaning rust off the rods before gunnite treatment. F. O. A.

Destruction of concrete by active carbonic acid. KARL BIEHL. *Zement* **17,** 1102–5 (1928).—The attack of concrete by certain waters is due to the active CO_2 present. While it is possible to compute the amts. of the gas present in its several combined and free forms, the p_H detn. is considered the most definite information regarding the corrosive properties of the water. H. F. K.

Alite. ERNST JÄNECKE. *Zement* **17,** 756–60, 792–7(1928); cf. *C. A.* **21,** 999.—A full discussion of the constituent minerals of cement clinker and their characteristics is given, including compn.-temp. diagrams and thin-section photomicrographs. The minerals are alite ($8CaO.Al_2O_3.2SiO_2$), belite (beta $2CaO.SiO_2$), celite ($2CaO.Fe_2O_3$ in isomorphous mixt. with $4CaO.Al_2O_3.Fe_2O_3$) and felite (probably alpha $2CaO.SiO_2$). The alite and belite are similar in compn. except for the substitution of Al for half of the SiO_2. These are isomorphous and give practically identical Röntgen-ray patterns, yet are not often found as mixed crystals except where aided by the presence of considerable amounts of Fe_2O_3. No $3CaO.SiO_2$ exists as such. The CaO in alite may be replaced by BaO and SrO. The setting and hardening of cements depend upon the formation of hydrates of CaO, $2CaO.SiO_2$, and $2CaO.Al_2O_3$ at the expense of alite. Belite hydrates more slowly. Celite seems to be converted into $2CaO.Al_2O_3.6H_2O$ and $2CaO.Fe_2O_3.6H_2O$. H. F. K.

The achievements of the U. S. S. R. (Russia) in the investigation and production of siliceous building materials during the past decade. B. SHVEZOV. Inst. Silicate Study, Moscow. *Intern. Congress Testing Materials* **1927,** II, 240–9. F. O. A.

Effects of moisture changes on building materials. R. E. STRADLING. Dept. Sci. Ind. Research (Brit.). *Building Research Bull.* No. **3,** 22 pp.(1928).—A résumé of the effects of free water, combined water and sorbed water. In addn. to brief discussions of direct disintegration, soln., osmotic pressure, transmission, crystn. and frost action, typical curves showing the effect of the quantity of sorbed water on the crushing strength and the stress-strain ratio are given. A well-selected bibliography is included. RAYMOND WILSON

Specifications for alabaster. PETER P. BUDNIKOV. *Zement* **17,** 1070–1(1928). H. F. K.

Structural gypsum. HENRY J. SCHWEIM. *Pit and Quarry* **16,** No. 3, 53–62, 87–9 (1928).—A résumé of test data on strength and other physical properties of gypsum mortar. RAYMOND WILSON

Slate. CHAS. H. BEHRE, JR. *Mineral Ind.* **36,** 527–31(1927).—Production, technology and uses are discussed. A. B.

Production and hardening of building materials of slag. FRIEDRICH HUTH. *Allgem. Brauer- u. Hopfen-Ztg.* **67,** 1151–2; *Chem. Zentr.* **1927,** II, 1747.—A brief description of the manuf. of building stone from slag. C. C. DAVIS

Methods for and results of rock-tests for road-making purposes. RAGNAR SCHLYTER. *Intern. Congress Testing Materials* **1927,** II, 375–97.—The testing methods of the U. S. Bureau of Roads are emulated since these "had advanced farthest in respect of being able to utilize and benefit by the test results for judging the suitability of a road-making material for its purpose." F. O. A.

Volume changes in sand with varying moisture content. E. STAUDT. *Zement* **17,** 1077–8(1928).—The bulking of 2 sands of similar screen analysis was from 25 to 38%

when the moisture content was 4–5% in each case. Higher moisture content decreased the bulking effect. H. F. K.

Testing the compressive strength of brick. H. BURCHARTZ. Materialprüfungsamt, Berlin. *Intern. Congress Testing Materials* **1927**, II, 315–20.—The old method of cementing 2 half bricks together and then placing in the compression machine after making the sides parallel does not give as good results as with cubical specimens cut from the bricks. Cylinders cut from the brick gave the lowest strengths. The size of the cube has some effect. F. O. A.

The effect of the composition of the mortar and of the quality of the stone on the weathering of masonry. J. A. VAN DER KLOES. *Intern. Congress Testing Materials* **1927**, II, 309–14.—The expansion of Na sulfate as it crystallizes from supersatd. soln. is taken as an indication of the danger to masonry of crystg. salts. An instance is cited of a masonry wall being struck lightly whereby the surface crust was broken and the soln. which filled the wall could leak out. The danger of excess lime in mortar may sometimes be serious and should be avoided by adding some pozzolanic material to combine with it. F. O. A.

Rapid freezing tests of stones. ANON. *Intern. Congress Testing Materials* **1927**, II, 280–308.—Cubes of 7 cm. edge are dried at 100° for 24 hrs., placed in distd. water and the pressure is lowered to 60 mm. for 15 min. They remain in the water for 7 days at atm. pressure and are then plunged into a $CaCl_2$ soln. of 25° Bé. for 4 hrs. and are then washed with water. F. O. A.

A photographic study of the weather resistance of certain sandstone. LEO MADDALENA. *Intern. Congress Testing Materials* **1927**, II, 275–9. F. O. A.

Weather resistance of rocks. A. STEUER. Hochschule, Darmstadt. *Intern. Congress Testing Materials* **1927**, II, 263–6. F. O. A.

The origin and weathering of stones in old Dutch buildings. A. L. W. E. VAN DER VEEN. *Intern. Congress Testing Materials* **1927**, II, 267–74. F. O. A.

Instructions for the cutting and preservation of timber for mines. SALVATORE FOIS. *Rass. min. met. ital.* **68**, 73–7(1928).—A description, including various methods for preserving the wood by treatment with chemicals. C. C. DAVIS

The aging of wood by ozone. ROGER LYON. *Chimie & industrie* **Special No.**, 662–4(April, 1928).—The changes undergone by wood on seasoning by prolonged storage comprise formation of amorphous products in the cells of the medullary rays and of the ligneous parenchyma, increase in the tannic compds., and increase in the acidity resulting in decrease of the p_H value of the solns. obtained by maceration of the wood. These changes do not take place in the kiln-drying of wood, but do take place in the artificial aging by means of O_3, a 2-months' treatment giving the wood the same properties as several years of natural aging. A. PAPINEAU-COUTURE

Industrial application of p_H: distinction between green and seasoned wood. R. LEGENDRE. Office national des recherches et inventions. *Chimie & industrie* **Special No.**, 665(April, 1928).—See *C. A.* **22**, 999. A. PAPINEAU-COUTURE

Gypsum (MYERS) **18**. The determination of free lime (RATHKE) **7**. P [manufacture of slag cement] (Brit. pat. 285,055) **18**. Rubber-surfaced roads, floors, etc. (Brit. pat. 285,203) **30**.

Le ciment portland artificiel. Fabrication, propriétés. Mortiers et bétons. Bruxelles: S. A. M. Weissenbruch. 120 pp. F. 10.

NEWELL, A. C.: **Wood and Lumber.** Peoria, Ill.: Manual Arts Press. 211 pp. Reviewed in *Expt. Station Record* **58**, 646(1928).

Cement. JOHN A. THOMPSON. Fr. 635,503, June 3, 1927. Cellular cement made by chem. reactions which expand the cement is allowed to set under reduced pressure.

Portland cement. AMMELUTHER WERKE BRAUNSCHWEIG DER MIAG MÜHLENBAU UND INDUSTRIE A.-G. Brit. 284,294, Jan. 27, 1927. A white cement is produced from colored raw materials by adding small quantities of materials such as metallic halogen compds., phosphates or borates, which on heating give colorless melts, with the coloring components of the raw materials. Reducing agents and fluxes also may be used. Brit. 284,295 specifies the production of colored cements from colored raw materials with the further addn. of pigments such as oxides of Cr, Ni, Co and Cu, together with inorg. salts such as metallic halogen compds., phosphates and borates adapted to combine with the pigments to form colored melts on heating. With ferru-

ginous raw materials the calcination is effected under reducing conditions and metallic iron is afterward removed.

Cellular cementitious materials. George B. Hinton. U. S. 1,687,067, Oct. 9. A cement pulp is aerated in the presence of a frothing flotation agent such as a suitable oil by use of small bubbles of air of substantially the size of the pores desired in the finished product. These bubbles may be formed by subdividing an air stream by passing it through a screen in an app. which is described. Cf. *C. A.* 22, 1026.

Concrete. Harold P. Hayden (to Barber Asphalt Co.). U. S. 1,684,624, Sept. 18. In effecting curing of concrete and stabilization of its water content, the concrete, when poured, is provided with a permanent impervious bituminous coating.

Concrete. Harold P. Hayden (to Barber Asphalt Co.). U. S. 1,684,671, Sept. 18. Evapn. of water from cement concrete during the curing period is prevented by applying an adherent film of asphalt paint or other suitable material impervious to water.

Reënforced concrete. Richard E. Dill. U. S. 1,684,663, Sept. 18. During the setting of green concrete contg. reënforcements, bonding of the reënforce with the concrete is prevented by coating with asphalt or the like and the reënforce is finally subjected to tension.

Asphaltic road material. William C. West (to West Process Pavement Co.). U. S. 1,685,304, Sept. 25. See Can. 279,421 (*C. A.* 22, 2836).

Paving. Berry, Wiggins & Co., Ltd., and H. H. Holmes. Brit. 284,908, May 16, 1927. Graded stone or the like used in road making or foundations is mixed with dry powdered material such as chalk, flue dust or granite dust which absorbs water from tarry material subsequently applied and serves thus to increase the viscosity of the latter.

Artificial stone. G. Knudsen (trading as Borgestad Fabrikker). Brit. 284,576, Oct. 23, 1926. A filler of granular olivine mineral or of Mg orthosilicate is mixed with a binder of material such as talc and MgO, which combine when heated to form Mg orthosilicate. The mixt. is formed into a paste with water, sirup or the like, molded and finally heated to somewhat below the m. p. of Mg orthosilicate, to obtain an artificial stone resistant to heat and to alkalies.

Porous artificial stone. K. Schenkel. Brit. 285,470, Feb. 19, 1927. Grain starch 2 is formed into a gel with water 12 parts and water 70 parts more is added. About 10% of calcined gypsum is then added and the resulting mass is molded. When set the product may be used as an absorbing medium for drying or in elec. storage batteries, etc.

Sheet material for flooring. A. O. A. Backstrom. Brit. 284,205, Jan. 24, 1927. A mixt. such as wood pulp and waterglass is pressed into sheets which are suitable for use as a backing for parquetry flooring.

Surface resistant to abrasion. Colin G. Fink and Arthur H. Kopp (to American Abrasive Metals Co.). U. S. 1,686,150, Oct. 2. Articles such as stair treads comprise a base of iron or other suitable cast metal in the surface of which grains of carborundum, emery or other wear-resisting material are embedded and these grains are individually surrounded by an alloy such as Sn alloyed with the adjacent iron.

Bituminous compositions. H. Laderer. Brit. 284,246, Jan. 25, 1927. A mixt. contg. natural bitumen and shale dust is used for road making or for manuf. of roofing tiles, building blocks, drain pipes, pillars, etc.

Synthetic resin fiberboard. Albert L. Clapp. U. S. 1,684,755, Sept. 18. Wood flour and a pulverized synthetic resin are incorporated into an aq. cellulosic pulp, the pulp is sheeted and the sheet is subjected to heat and pressure.

Saturator for testing samples of roofing felt, etc. Floyd W. Adams (to The Barrett Co.). U. S. 1,685,078, Sept. 25.

Kiln construction for drying wood, etc. John F. Hope and John T. Hope. U. S. 1,684,627, Sept. 18.

Preserving wood. Louis Bringer. Fr. 635,341, May 31, 1927. Wood is submitted alternately to heat and vacuum to increase the porosity of the wood, then cold liquid antiseptic is allowed to flow on the wood, which is reheated with hot air or steam.

21—FUELS, GAS, TAR AND COKE

A. C. Fieldner

Report of the National Fuel and Power Committee. Lord Melchett, *et al.* *Chemistry & Industry* 47, 998(1928).—The recommendation is made that the Government make an investigation in a limited, designated area, of the technical and economic

aspects of an area gas-supply system comprising an interconnecting network of pipe lines fed by a no. of gas works, coke ovens and the like. Work on the low-temp. carbonization of coal is commended, and the statement is made that "there appear to be several processes now entering the com. stage." Improvement in coke-oven practice is urged strongly, better utilization of low-grade fuel (perhaps for power generation at the mine itself), a more general exchange of technical information among fuel technologists and users, further experimentation in the use of high-pressure steam and pulverized fuel in ships of different types, the advantages of the purchase and sale of coal upon specifications, and the need for fuel technologists are treated in the Report.
W. C. Ebaugh

Notes on recent developments in fuel technology. R. Wiggington. *Fuel in Science & Practice* 7, 427–9(1928).—Brief reviews of the following subjects: coal *vs.* oil, elec. ships, luminous bacteria, water purification. D. A. Reynolds

Further development in the recovery of fuels from furnace residues in Germany and abroad through the process of dry magnetic treatment. G. Ullrich. *Wärme* **50**, 563–5; *Chem. Zentr.* **1927**, II, 1777.—A review, with a description of a plant of the German railways, a gas works in England and power plants in the Philippines and in Japan. C. C. Davis

Use of the Endell heating microscope for testing solid fuels. E. Berl and H. Schildwächter. *Brennstoff-Chem.* 9, 159–60(1928).—The app. consists of a small elec. tube furnace, the tube of which is illuminated by a small arc light, and a microscope of 45 diam. magnification. By use of an inert atm. (H_2, N_2 or CO_2) in the tube the destructive distn. of a coal sample can be observed. Temps. of initial decompn., tar evolution, coke formation and end of gas formation are observed. J. D. Davis

Ignition of solid fuels. H. Greger. *Brennstoff-Chem.* **9**, 232–4(1928).—Factors influencing ignition of solid fuels are discussed and lab. app. is described for detg. ignition temps. The app. consists of a vertical glass tube 20 mm. in diam., the bottom of which projects into a sand bath contained in an iron crucible heated by a gas flame. A quartz-glass thermometer graduated to 750° is passed through a stopper at the top of the tube and the bulb is covered with the 8-cm. sample sized 10 to 20 mesh, which rests on the sand at the tube bottom. Air (1 l. per min.) is drawn through the heated sand and thence through the sample by a water pump connected to a top outlet of the tube. A uniform heating rate (8–10° per min.) is maintained until a sudden rise in the temp. shows the ignition point has been reached. J. D. Davis

Waste liquors from the dry distillation of solid fuels. I, II, III and IV. K. Thumm. Landesanst. f. Wasser-, Boden- u. Lufthyg., Berlin-Dahlem. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **1**, 141–9(1925); **2**, 1–9, 109–13, 236–42(1926); *Chem. Zentr.* **1927**, II, 1744–5.—The work comprises a very detailed description of the aq. decompn. products which are formed during the dry distn. of solid fuels, such as mineral coal, brown coal, peat and wood. Special reference is made to the phenol content, with numerous references to the literature. C. C. Davis

What is being done about prepared liquid fuels. A. A. Potter and H. L. Solberg. Purdue Univ. *Power* **68**, 604–5(1928).—A discussion of *liquefied coal, synthetic motor fuels, colloidal fuel* (which is a suspension of coal dust in fuel oil), *alcohol* and *shale oil.*
D. B. Dill

Dynalkol. Hugo Novák. *Chemický Obzor* **1**, 89–91(1926); *Chem. Zentr.* **1927**, II, 1319.—N. points out the advantages in using dynalkol (mixt. of 60% benzene and 40% alc.) as a motor fuel. A special advantage is the possibility of using high compression and at the same time having an easy start of the motor. G. Schwoch

Excise on benzene for internal-combustion motors. J. S. Turski. *Przemysl Chem.* **12**, 307–14(1928).—Increased use of mixed motor fuels is recommended.
A. C. Z.

Incomplete combustion in automobile engines and its economical and hygienic significance. W. Liesegang. *Z. angew. Chem.* **41,** 712-3(1928).—L. reviews the published data, which show that combustion in an automobile engine is far from complete, and that the products of incomplete combustion, especially CO, are a menace to public health in the large cities. G. Calingaert

The calculation of flame temperatures. A. J. V. Underwood. *Fuel in Science & Practice* **7,** 455-63(1928).—The calcn. of flame temps. is laborious. A method of calcn. based on that of Goodenough and Felbeck has been used to construct charts, called dissocn. charts, from which the temp. can be obtained graphically. From the energy contents of CO_2, H_2O and O_2 in waste gases the flame temp. can be detd. from the charts. D. A. Reynolds

New tests with benzene separators. H. Rossberg. *Gesundh. Ing.* **51,** 330-3 (1928).—Two sepg. systems, the "Kutzer" built by G. Horkner and the "Argus III" built by Schnutenhaus and Linnman, were tested. Tables contg. the exptl. results are given. Efficiencies for the first type ranged from 92.0 to 99.4%, while for the second type the efficiencies ranged from 54.1 to 98.5%. Wayne L. Denman

Fuel pumps of compressorless Diesel engines. Otto Holm. *Arch. Wärmewirt.* **9,** 258-61(1928).—Many details are given of the design and construction of these pumps. Ernest W. Thiele

Clear heat diagrams. F. W. Stockmeyer. *Arch. Wärmewirt.* **9,** 223-4(1928).—S. proposes to represent heat quantities by areas, vertical distances representing temp. and horizontal, heat capacity. Ernest W. Thiele

High-capacity boilers for use with wood-working waste. V. W. Granberg. *Arch. Wärmewirt.* **9,** 69-74(1928).—A Finnish boiler plant for handling a great variety of waste is described. The upper portion of the grate is nearly horizontal, the larger part is steeply sloped, with a small horizontal grate for ash at the bottom. Up to 43.5 kg. per sq. m. per hr. was evapd. at 20 atm. with good economy. E. W. T.

Improvements of steam boiler plants. Peter. *Arch. Wärmewirt.* **9,** 157(1928).—P. proposes to reverse the direction of chain grates, so as to bring the ashes out the front. This would help ignition of the coal. He also describes a chain grate using wire screen, to be put in a fire-tube boiler. It was not found durable. E. W. T.

$10,600 saved yearly in a chemical plant. W. H. Scott. Merrimac Chem. Co., No. Woburn, Mass. *Power* **68,** 508-10(1928).—Savings were effected by installation and use of flue-gas thermometers, CO_2-recorders, steam-flow air-flow meters and steam meters. D. B. Dill

Some physical properties of marine animal oils. Henri Marcelet. *Chimie et industrie* **Special No.,** 531(April, 1928); cf. *C. A.* **21,** 3757.—Analysis of 40 different oils (nature of the oils and results of analysis not given in detail) was made to see if they were suitable as fuels in Diesel engines. Calorific values varied from 8593 (*Pseudorca* oils) to 10790 cal. (oil of *Centrophorus granulosus*), and with any given oil of given origin it increased with the lightness in color of the oil. The flash point varied from 175° (oil of *Gadus morrhua*) to 312° (oil of *Mustelus vulgaris*) and the burning point from 225° (oil of *Gadus morrhua*) to 352° (oil of *Macrorhinus leoninus*), the flash points being somewhat lower than, and the burning points approx. the same as, those of vegetable oils. The viscosity at 25° is in all cases above 2.5° Engler and in some cases it is very high; at 56° it is less than 4° Engler, and at 100° in most cases it is less than 1.7° Engler. A. Papineau-Couture

Utilization of marine animal oils in motors. Henri Marcelet. *Chimie et industrie* **Special No.,** 532-3(April, 1928).—See Lumet and M., *C. A.* **21,** 3727. A. Papineau-Couture

Coal and coke. R. W. Morris. *Mineral Ind.* **36,** 81-111(1927).—A review of the industry in the U. S. and foreign countries. A. B.

Some physicochemical properties of coal. F. M. Lea. Building Research Sta., Garston, Watford. *Fuel in Science & Practice* **7,** 430-43(1928).—The following properties of 35 coals were studied: the sorptive powers for H_2O and certain dyestuffs, the linear expansion of dry coal on wetting and the sorption of O_2. The results of a large no. of tests are given in 13 tables. The rate and amt. of sorption of moisture by coals from a satd. atm. are a characteristic property of a coal. This property runs parallel to the O content of coals in which this content is less than 10% but does not exist with coals of higher O content. The sorption of dyes by coals depends primarily on the coal and secondarily on the nature of the dye. Dye sorption is hydrolytic in type. There is no definite relation between the sorption of dyes by coal and that of moisture of O. The amts. of O absorbed at N. T. P. increases with the coals of higher O content, this relation being especially apparent on mixing the fine coal with $Ca(OH)_2$. The linear

expansion of coals on wetting varies widely with a max. of 2.08%. This expansion is greatest and most quickly reached with those coals of high O content. On a basis of the results obtained the coals are divided into 3 classes; these classes amount to what might be termed high, medium and low O content. The colloidal nature of coal is considered in explanation of the results. D. A. REYNOLDS

Analytical characteristics of coal. W. FUCHS. *Brennstoff-Chem.* **9**, 198–200 (1928).—The OH number of coals varies (analytical data given) from 65.9 in Kassel brown coal to 19.0 in Upper Silesian bituminous coal. For the detn. 1 g. dry coal is heated (water bath) with 50 cm. 0.1 *N* alc. KOH for 30 min., dild. with EtOH (so that the soln. contains not less than 75% EtOH at the end of titration) and titrated with 0.1 *N* H_2SO_4, with phenolphthalein. J. D. DAVIS

The composition of coal in relation to spontaneous combustion. WILFRID FRANCIS. U. S. Bur. Mines with the Brit. Safety in Mines Research Board. *Proc. Am. Gas. Assoc.* **1927**, 1392–8.—The various plant products contributing to the formation of the org. substance of coal fall into 2 groups according to their resistance to decay, (1) spore exines and cuticular tissues, and (2) resins. During the decay of a deposit of plant remains, the spore exines, cuticles and resins remain practically unchanged but the woody parts decomp. and eventually the *ulmins* are formed; these are defined as brown amorphous products of vegetable decay, which are usually sol. in alkalies. Ulminification is the main chem. process during the decay of plants. The ulmins are the most easily oxidized of all the ingredients of coal; the spore exines, cuticles, and hydrocarbons are very resistant, and at low temps. the resins are slow to oxidize. The changes in compn. of the ulmins which cause the reduction in danger from spontaneous combustion are those of condensation, dehydration and possibly polymerization. Comparative detns. of the rates with which the ulmins of various coals will oxidize may be used as a measure of their liability to spontaneous combustion. At present these values are being obtained by actually measuring the vols. of O_2 consumed during the oxidation of known wts. of the coal under standard conditions It is hoped that a chem. oxidizing agent may be used. The inert ingredients of coal, the *vitrain* bands, are easily reduced to powder by ordinary handling, which increases the rate of oxidation of coal, chiefly on account of the increased surface formed. *Durain* is safe from oxidation, while *clarain* is intermediate in danger between the vitrain and durain. Mother of coal, or *fusain*, contg. as little as 30% ulmin, is easily oxidized, even at low temps., and excessive local heating may easily occur. This material, however, is a minor constituent of coal. J. H. PERRY

How composition affects burning qualities of coal. A. A. POTTER AND H. L. SOLBERG. Purdue Univ. *Power* **68**, 183–6(1928).—A general discussion of the influence on burning qualities of H_2O, O, S, N and clinkering properties. D. B. DILL

The mineral constituents of lump coal. R. LESSING. *Z. Oberschles. Berg- u. Hüttenmänn. Ver. Katowice*, No. **4**, separate 7pp.(1928); cf. *C. A.* **21**, 2370.—The difference between ash and mineral contents of coal is explained and, on the basis of their probable sources, the mineral constituents of coal are classified into 6 groups. The av. ash contents of the components of English coals, clarain, vitrain, durain and fusain, are: 1–2, 1, 6–7 and 15%, resp. Complete quant. analyses of the H_2O-sol., the acid-sol. and the insol. portions of the ash from each of the 4 components are tabulated. The results are interpreted in terms of the minerals originally present in, and their influence on the characteristics of each portion of the coal. No homogeneity was found in the ash content of coals, but its chem. compn. dets. the heat-resistance of the ash. The importance of compn. and quantity of ash in coals in their uses for power generation and coke and gas production is discussed. It is estd. that approx. 25,000,000 tons of coal ash is produced per annum in Great Britain and the economic losses incident to the handling and transportation of this useless material emphasizes the need for clean coal. The effects of inorg. constituents in coal on its coking and gas-producing qualities are outlined. The data from many expts. to det. the catalytic effects of added amts. of certain inorg. compds. on the coking properties of sugar, cellulose and coal are given in 3 tables. The results are discussed in relation to their practical application in the coal-carbonization industries. A bibliography of the author's publications on this subject is given. W. W. HODGE

Investigation of the microbiology of coals in the seam. R. LIESKE AND E. HOFMANN. *Brennstoff-Chem.* **9**, 282–5(1928); cf. *C. A.* **22**, 4417.—Samples were taken from several bituminous coal mines of the Ruhr district, extreme care being taken to use sterile app. for sampling to avoid contamination. The coal beds were sampled at depths of 400 to 750 m. and samples of mine water and mine air were also taken. The mine water was seldom sterile and the air always contained bacteria, the number of which

did not vary greatly in outgoing and incoming air. In some entries iron bacteria and S bacteria (*Thiothrix*) were found. It was learned that the over burden, even at great depths, was not sterile. Bacteria were almost always found in the coal beds themselves. These belonged mostly to the subtilis and particularly the mesentricus group. Frequently cocci were found. Fungi were found in the mine air and in old workings but not in the unexposed coal bed. Coal bacteria were found not to be pathogenetic. J. D. DAVIS

The classification of coal. SAMUEL W. PARR. Univ. Illinois Eng. Expt. Sta., *Bull.* No. **180,** 59 pp.(1928).—The growth of the U. S. as a coal-producing nation from 1322 tons (all anthracite) in 1821 to approx. 600,000,000 tons per annum now is noted and an historical sketch of previous works on coal classification is given. The fundamental factors in coal classification, geological changes, O content, volatile matter, inert materials, calorific value and compn. of coal types are discussed. Unit coal is defined as the pure coal substance altogether apart from the extraneous or adventitious material which may have become assocd. with the combustible org. substance of the coal; and the following formulas are developed: non-coal $= 1.08\,A + 22/40\,S$; unit coal $= 1.00 - (1.08\,A + 22/40\,S)$; unit B. t. u. $= \dfrac{\text{indicated B. t. u.} - 5000\,S}{1.00 - (1.08\,A + 22/40\,S)}$, unit volatile $= \dfrac{\text{volatile as detd.}}{1.00} - \dfrac{(0.08 + 0.4\,S)}{(1.08\,A + 0.55\,S)}$, where A = ash as weighed and S is sulfur. The accuracy of the formula for unit coal is verified by calcns. tabulated along with analytical data on float and sink portions of 11 typical coals from widely sepd. localities. Comparative heat values for pure coal substance as calcd. by 3 methods are also tabulated. The Parr system for classification of solid fuels is explained and illustrated with 3 coördinate charts plotting B. t. u. (unit coal) from 9000 to 16,500 against % volatile matter (unit coal). The 1st chart shows the type areas of the system, anthracite (type 1), semi-anthracite, bituminous A, B, C and D, lignite and peat. The cannel (type 9) area is not definitely outlined and wood (type 10) with an av. unit volatile of 70.05% and unit B. t. u. of 8650 is equally distinctive and falls entirely outside the chart's lowest B. t. u. line. The 2nd chart shows the location of type samples of American coals and the 3rd gives the classification of 625 coals from all parts of the U. S. The analytical data, with reference where secured, for these coals and for 150 coals from other countries of the world, together with calcns. of unit B. t. u., unit volatile, the geographical source and Parr classification of each coal are given in 24 tables. Comparisons are made between the Parr, Seyler and Bur. of Mines classifications. A bibliography of the development of methods of classifying coals (111 articles from 1877 to 1927) is included. W. W. HODGE

Astrurian coal occurring in the territory of the Cantabrian Cordilleras. P. KUKUK. *Glückauf* **63,** 821–9; *Chem. Zentr.* **1927,** II, 800.—Data are given on the quality of coal mined in Astruria. It yields 56.5–70.9% coke, 29.0–43.5% volatile matter, and 2.79–13.20% ash. Its calorific value is 4690–6090 kg. cal. Stratigraphical conditions of Spanish carbon are described. J. S. REICHERT

The coal fields of Scotland. The carbonization of "Kinneil gas." C. H. LANDER. Dept. Sci. Ind. Research. *Fuel Research, Phys. Chem. Survey Nat. Coal Resources,* No. **11,** 39 pp.(1928).—The location, geological setting and section drawing are given of the 6-ft. seam of Kinneil gas coal. The physically distinguishable components, vitrain, fusain, durain, cannel lumps, stone inclusions and fire clay, present in the 500-ton "run of mine" shipment of this coal used for the tests are described. The normal coal just floated and all impurities sank in liquids of 1.35 and 1.60 sp. gr., resp.; hence this coal after crushing could be easily cleaned to reduce ash content from 7% to about 4%. The mean proximate analysis of 360 tons of air-dried coal was: moisture 2.3, volatile matter less moisture 33.5, fixed C 57.2, ash 7.0%. The mean ultimate analysis of 175 tons was: ash 7.09, C 78.16, H 4.86, N 1.45, S (combustible) 0.38, difference O and errors 8.06%. The mean C:H ratio was 16.1:1. Results of the Gray-King carbonization assay of the coal at 600° are compared with a similar assay of "Mitchell Main Gas" coal. Fusion pt. detns. on ash from Kinneil coal showed no change except a slight surface glazing in an oxidizing atm. to 1450° and in a reducing atm. to 1375°. With from 40 to 50 tons per run 4 carbonization tests (2 each with 5% and with 10% steam) were made in continuous vertical retorts; and 5 tests in horizontal oval D section retorts using 28 to 50 tons per test. The details of the tests, tables of complete analytical data on coal used, and coke, tar, gas, liquor and $(NH_4)_2SO_4$ obtained in each test are given; also temps. and pressures in the carbonizing systems, yield, wt., and thermal balances, and screening tests of coal used and cokes formed. Kinneil coal worked well

in both types of retorts. Yields obtained by using 5.2% steam in the vertical retorts compared with results in the horizontal retorts were, resp., per ton coal processed: coke 1261 and 1378 lbs.; gas 16,770 and 12,300 cu. ft. of 477 and 574 B. t. u. per cu. ft.; tar 15.0 and 9.4 gals.; $(NH_4)_2SO_4$ 23.4 and 26.6 lb. Three appendices present the results of expts. showing that: (1) Kinneil coal on low-temp. carbonization at 625° produces an excellent smokeless fuel coke; (2) each of the high-temp. cokes and the low-temp. coke were satisfactory for firing a Lancashire boiler; (3) the high-temp. cokes gave good results when used to produce fuel gas in a suction-gas plant and in a producer in a horizontal retort setting, but excessive clinkering occurred in the water-gas plant. Two folded plates give diagrammatic elevation and section drawings of the vertical and the horizontal high-temp. retort installations with their tar and gas-treating equipment as constructed at H. M. Fuel Research Station, Greenwich, Eng.

W. W. HODGE

Resistance of various coals to shock and abrasion. D. J. W. KREULEN. *Brennstoff-Chem.* 9, 264-7(1928).—Several coals of differing rank are tested by methods very similar to those commonly applied to coke in the shatter and tumbler tests. In the shatter test K. uses 2 kg. coal (sized on sieves with round holes between 30 and 40 mm. diam.), which he drops successively from a wood box 1500 cm. on to an iron plate. After each fall the coal is sieved through sieves having 30, 20, 10 and 5 mm. diam. round holes and the wt. of coal passing each is recorded. Results are given by curves showing the relation of no. of falls to each size produced. For the tumbler test a cylindrical, rotating, sheet-iron box 30 cm. diam. × 15 cm. long is used. The charge and size of coal are the same as that above. A test consists in rotating the charge 60 times at 60 r. p. m., sieving as above, and repeating the operation. Results are shown by curves giving the relation of weights of sizes produced to number of rotations. The curves are very similar to those of the shatter test. A young Welch coal tested resisted abrasion better than shock. This was a very hard coal, which tended to split on falling but because of its hardness did not abrade readily. Resistance to shatter and to abrasion often varies inversely with rank of coal. This explains why some young coals (intrinsically sensitive) prove less sensitive to spontaneous heating than older coals; their oxidation is retarded by absence of fine coal normally produced on handling.

J. D. DAVIS

Hydrogenation of coal in the presence of catalysts. B. HLAVICA. *Brennstoff-Chem.* 9, 229-31(1928).—Five different coals ranging from 71 to 86% C (basis of coal substance) were hydrogenated dry in a 1.8-l. rotating autoclave at temps. of 430° to 470° with initial pressures of 65 to 110 atm. Oxides and chlorides of the following metals were tested as catalysts and their efficiencies compared with Fe_2O_3 recommended by Bergius: Zn, Al, Co, Cu, Ni, K, Ca and Sn. Relative efficiency of some of the best catalysts (compared with Fe_2O_3 taken as 1) was: $Fe_2O_3 + ZnCl_2$ 1.43, $Co_2O_3 + CuO$ 1.65, $NiCl_2$ 1.7, CuCl 1.95, ZnO + KOH 1.7. As regards conversion of the coal into oils, the best result was obtained with $NiCl_2$; liquefaction of the coal was practically complete and by far the most of the H_2 used formed liquid and solid products. The amt. of catalyst used was usually 10-20% of the charge. H. considers that hydrogenation proceeds in 3 stages: (1) At 300° to 400° there is rapid absorption of H_2 and deoxidization with H_2O formation and conversion of the coal into an asphalt-like mass; (2) H_2 is still absorbed rapidly and the asphalt mass becomes steadily softer until all the coal is converted; (3) rapid splitting of mols. takes place with formation of gases and low-boiling oils. J. D. DAVIS

The agglutinating value of American coals. W. H. FULWEILER AND T. K. CLEVELAND. U. G. I. Contracting Co. Lab., Philadelphia. *Proc. Am. Gas Assocn.* **1927**, 1399-1410.—The proximate analysis of a coal does not indicate its coking qualities or agglutinating value. A coal contg. the highest proportion of agglutinant (β and γ compds.) does not necessarily form the best coke under ordinary conditions of carbonization. A review is given of the lab. methods for detg. the coking power of coals, which lead up to Barash's method (*Gas J.* Special No., Nov. 9, 1925). B.'s method was used to det. the agglutinating values of 72 U. S. coals (from the Va., W. Va., Pa., Ky., Ala., Ill., districts and from one English district). No direct correlation of the agglutinating value and the amt. of volatile matter present is possible. If the coals are classified according to the location of thir resp. seams, it is found that the Ky. coals fall within a fairly small area of the plot indicating a high-volatile matter concn. with a correspondingly low agglutinating value. With the Va. coals, a regular increase in the volatile matter concn. is accompanied by an increase of the agglutinating value. The W. Va. coals show no regularity, while those from Pa. are similar to the Ky. coals. The coking test described by Barash was applied to several of the coals. Those having

an agglutinating value of 1:15 or less gave a dense coke with little swelling; while those with an index above 1:15 usually gave a porous coke accompanied by extensive swelling. An exception to this rule is an Ill. coal, having an index of 1:22, which gave a dense, hard coke with little or no swelling. A definite relation between the agglutinating value of a coal and its relative operating efficiency in a water-gas generator seems possible. J. H. PERRY

The drying of coal. FELIX BRAUNEIS. *Montan Rundschau* **20,** 430–3(1928).—The drying of coal is desirable because it reduces freight charges and makes the coal more suitable for use. If half the 300,000 cars of brown coals mined per annum in Austria are shipped it means the transporting of 70,000 carloads of water and 15,000 carloads of clayey materials. Practical drying involves the removal of free, but not of hygroscopic water and must be carefully controlled, diffusion of moisture from the interior of the coal keeping pace with evapn. from the surface, or cracking and crumbling of the coal results. Under favorable conditions air-drying reduces the H_2O content of raw brown coal from 50% to 25%, but climatic conditions are uncertain. Artificial methods of drying mentioned are: with steam direct and indirect, industrial gases, air or electricity passed through the coal, or electric osmosis. The use of steam, direct contact and of hot gas streams are the most important methods for drying coal. These 2 methods are discussed at length from the standpoint of the physics involved; capillarity of the coal, diffusion, surface tension and vaporization, heat transfers, elasticity of the coal cells, size of coal particles, time rates and temp. differentials best to use. Calcns. given show thermal and fuel requirements for drying a brown coal of 36 and 15% moisture. Calcd. increase in heating value by reduction of H_2O content of coal is 30%; by reducing both H_2O and ash the increase is 40% in calorific value. By drying and purifying the medium-grade Austrian brown coals the quantity of coal imported could be reduced. W. W. HODGE

The dry cleaning of coal. A. N. HARRISON SLADE. Univ. of Birmingham. *Trans. Inst. Mining Eng.* **75,** 136–53(1928).—Appliances for dry-cleaning coal date back to 1850. The first modern type of successful pneumatic sepn. was developed by Sutton and Steel in the U. S. A. (1905). The Birtley "Wye" separator uses a reciprocating inclined table, the bed of which is perforated and covered with riffles. The raw coal is fed on the table and air passing through the bed renders the coal bouyant and brings about stratification. The shale is trapped in the riffles and the clean coal travels across the table. Lab. tests have shown a max. efficiency of 86.5%. C. W. O.

Recent progress in the technic of coal washing. CHARLES BERTHELOT. *Rev. ind. min.* **1928,** No. 178, 203–27.—The washing of slimes and dust, either in special rheolaveurs or in flotation app., assures a net increase of 10 francs per ton for these products. In order to reduce the ash content of the fines and slimes or float dust, it is necessary to drain them, wash them in clean water and deliver them *directly* into the bucket conveyor which then carries them to the washed fines. The system of methodically decanting the wash water and then cleaning it by flotation appears to hold much promise of success in that it appears to give a means of avoiding pptn. of clay in the fines. Eliminating part of this clay will reduce the ash in the washed coal. Coal washing has now been reduced to a science resting on definite laws of physics and chemistry. C. W. OWINGS

Clean coal in the coking industry. R. LESSING. *Gas World* **88,** Coking Sect., 58–62(1928).—Considerable errors are introduced, in the study of coal, by failure to distinguish between ash and the mineral matter present in the coal, because of changes during ignition, such as loss of CO_2 from carbonates, dehydration, oxidation, etc. Ash compn. and content, and their variation with particle size in graded specimens, are characteristic for the various coal components and are assocd. with their role in coal formation. Thus, the largely water- and acid-sol. ashes of clarain and vitrain represent original plant ash. The ash of fusain is derived from carbonates, etc., diffused by water into the decaying vegetable matter. This is assocd. with its segregation in cracks in the coal seams. Durain ash corresponds to clay in compn. Ash, in graded specimens, decreases in clarain, is uniform in durain and increases in dirt with decrease in size. Of 10% ash in coke, representing about 7% in the coal, all but 1–1.5% comes from dirt. It reduces the strength of the coke and produces breeze. F. S. G.

Bituminous coals of the Plauen District near Dresden. F. FOERSTER AND A. LANDGRAF. *Brennstoff-Chem.* **9,** 169–74(1928).—Five samples representing three beds of this region were analyzed and assayed for low-temp. carbonization yields. Forms of S and their behavior on burning were detd. and R, the pure coal substance, was calcd. from the results and from the ultimate analysis by the formula: $R = 100 - (a - 2.5b + 2.5c + 5/8d + f)$. Here, a = % ash detd., b = SO_4 sulfur in ash as

% of original coal, c = SO_4 sulfur in coal, d = pyrite S in coal and f = moisture in coal. The C in pure coal as derived by the formula was near 84%, the limit set by Bergius for normal coalification; *i. e.*, coalification under conditions of moderate temp. and pressure. J. D. DAVIS

The physical constitution of bituminous coal and coal seams. JOHN G. KELLETT. *Trans. Inst. Mining Eng.* 75, 400–12(1928).—Bituminous coal of Carboniferous Age when examd. macroscopically is seen to consist of fusain, vitrain and durain. These constituents may occur as sep. lenticles, but much of the coal seam consists of fine intercalations of these constituents. Often the naked eye cannot distinguish the sep. components. The so-called bright coal is termed clarain. The microscopic constituents of coal are anthraxylon, residuum, microspore and macrospore exines, resins, rodlets, cuticles and fusain. The relation between the microscopic and macroscopic components of coal has been shown to be: (*a*) vitrain is composed of anthraxylon; (*b*) durain is microscopically complex, consisting mainly of exines, resins, cuticles and residuum; (*c*) clarain is distinguished from durain by progressive addn. of anthraxylon; (*d*) the brightness of the coal is proportionate to the content of anthraxylon. C. W. OWINGS

The distribution of ash in bituminous coal seams. JOHN G. KELLETT. *Trans. Inst. Mining Eng.* 75, 413–20(1928).—The application of the petrological microscope to the study of residual ash affords a quick and accurate method of detg. the principal constituents. A microscopic study of the residual ashes from vitrain, fusain and durain has largely confirmed the deductions of Lessing (*Trans. Inst. Min. Eng.* 60, 288(1920-1921); cf. *C. A.* 14, 1888, 1889). From the point of view of coal cleaning it is of interest to note that vitrain cannot be sepd. from its ash (this amounts to less than 1%); durain carrying clay finely disseminated through its mass, amounting to 6%, cannot reasonably be cleaned; this also applies to clarain carrying vitrain ash and fine clay, and to fusain carrying typical "fusain ash." By means of a microscopic examn. it is possible to det. the constituents of any coal ash in terms of the earthy vitrain ash, the kaolinite rods of fusain ash, clay, ankerite, and pyrite residues. The principal ash constituent in coal is generally clay, usually in bands. Colloidal clay is occasionally found in fusain. C. W. OWINGS

The influence of bitumens extracted from coal with tetralin under pressure on its coking properties. E. BERL AND H. SCHILDWÄCHTER. *Brennstoff-Chem.* 9, 121–2 (1928).—200 g. coal is extd. repeatedly with 500 cc. tetralin in an autoclave at 250°. The exhausted residue is extd. with EtOH until free from tetralin. The ext., free from tetralin, is sepd. into oily and solid bitumen according to Fischer (*C. A.* 19, 717, 1767) by soln. of the former in petroleum ether. On mixing back the sepd. bitumens with the extd. residue and coking, it was found that solid bitumens promote swelling and oil bitumens cause coke cementation (agreement with Fischer); however the degree of swelling and of coking of the original coal was not at all closely simulated when the mixts. were used. J. D. DAVIS

The fundamentals of coal blending and the production of solid smokeless domestic fuel. J. G. KING. *Gas J.* 183, 668–70(1928).—A general discussion. F. S. G.

Progress in central-station use of pulverized coal. E. H. TENNEY. *Mech. Eng.* 50, 767–73(1928). E. J. CRANE

Powdered coal or grate firing? N. F. NISSEN. *Arch. Wärmewirt.* 9, 55–8(1928).—A defense of grates. ERNEST W. THIELE

Automatic grate firing and clinkering. HANS LANGER. *Arch. Wärmewirt.* 6, 273–5(1925).—The *Pastrnák stoker* is described. When fuel is to be added, a long car running on rails shoves the fuel on the grate toward the door, and deposits fresh fuel on the back of the grate. Test results in a cellulose plant are given. E. W. T.

Results with the new "turbine" grate. ANON. *Arch. Wärmewirt.* 6, 299–301 (1925).—This is a fixed grate, for forced draft by steam injector, intended for fines and low-grade fuels. The cast-Fe grate sections fit together to form nozzles similar to those in a turbine. A number of boiler test results are given. E. W. T.

Flow resistance of powdered coal in air or other viscous fluids. WILHELM NUSSELT. *Arch. Wärmewirt.* 6, 61–3(1925).—The formulas for the velocity of fall of a coal particle given by Audibert (*C. A.* 16, 1850) and Blizard (*C. A.* 18, 3509) are incorrect. If r is the particle radius, W its velocity, and S and s are the densities of the particle and the fluid, respectively, then rS/W^2s is an arbitrary function of Reynold's modulus. This, however, does not check A.'s data. ERNEST W. THIELE

The Brand system of burning pulverized coal. ANON. *Engineer* 146, 321–2 (1928).—Details are given of two tests carried out on a Scotch boiler equipped with

the *Brand* system of burning pulverized coal. The pre-furnace maintains the temp. of the furnace at any desired point, either fusing or not fusing the ash, and also keeps down dust. The walls of the pre-furnace must be water-cooled or else lined with bricks of high Si-Al content. D. B. DILL

Burning crushed coal in suspension. JOHN F. O. STRATTON. *Power* **68**, 486–7 (1928).—Coal crushed to $^1/_4$ in. size is fed through a nozzle at the side of the furnace. Finer particles are burned immediately and larger particles fall on a reciprocating grate. The resulting coke and ash are fed by the grate to an upward nozzle through which pre-heated air passes at a velocity of 2530 ft. per min. Non-combustibles liquefy, forming dense particles, which fall into the ash pit. D. B. DILL

Plant hazards in the preparation and firing of powdered coal. FR. SCHULTE. *Arch. Wärmewirt.* **9**, 107–10(1928).—The regulations of the German coal commission on this subject are presented and discussed. ERNEST W. THIELE

The question of separating ash from powdered coal. H. W. GONELL. Staatl. Materialprüfungsamt, Berlin-Dahlem. *Arch. Wärmewirt.* **9**, 209–12(1928).—Tests on *air sepn.* were made in a glass lab. app. An artificial mixt. of powd. slag and coal could be sepd. fairly well after sieving; with a natural coal only the pyrite was removed. ERNEST W. THIELE

The carbonization of pulverized coal by the Bartling process. DAVID BROWNLIE. *Gas Age-Record* **62**, 442–4(1928).—The Bartling process uses pulverized fuel of the ordinary degree of fineness, that is about 90% through a 100-mesh screen and 60% through a 200-mesh screen. The main difficulty with such a process has been the sepn. of the carbonized coal dust from the conveying medium, generally recycled gas or steam. The Bartling process solves this difficulty by using the new "*Coriolis*" *separator*, which consists essentially of 2 flat steel disks, spaced about 2 mm. apart. One of the disks is stationary, while the other revolves at a peripheral speed of about 230 ft. per min. If the gas-dust mixt. is passed between the disks, the lower one being stationary, the gas next to the stationary disk has little rotary motion while the gas next to the other disk tends to attain the velocity of the disk. It is claimed that all the dust is thrown down by centrifugal force to the lower disk and leaving the disks drops by gravity, while the gas passes out and upward. In the Bartling process the pulverized coal is blown upward through an externally heated, short, cylindrical retort, by residual gas, where it is carbonized by direct contact with the walls and by radiation. It then passes up under the center of a revolving disk, the bottom of the separator acting as the stationary disk, and the gas and dust are sepd. LESLIE B. BRAGG

The burning of coal. K. SCHREBER. *Dinglers Polytech. J.* **342**, 97–102(1927).—By considering the important reactions and their equil. conditions during combustion in a hypothetical simplified fuel bed S. concludes that the coal on the grate at the ordinary grate temps. burns only with the help of the CO_2; only at very high temps. as in a blast furnace does the coal combine directly with O, and then only to CO. On the grate every particle of coal is surrounded with an envelope of CO, at the boundary of the envelope toward the particle the CO_2 changes to CO and on the boundary toward the gas phase the combustion of CO to CO_2 takes place. E. G. MEITER

Low-temperature carbonization of bituminous combustibles. F. H. MARTIN. *Rev. ind. min.* **1928**, No. 185, 359–64.—At the Bosen mine, Fiejus, France, a new type of mech. furnace was developed in 1925, perfectly adapted to treat shale difficult to treat. The shale has a content of 10–58% hydrocarbons, and an av. of 25%; the calorific value is 5091. The production of gas at 500° is 40% less than obtained when the temp. at which distn. is stopped is from 750° to 800°; at the latter temp. the heating value is 9850 cal. The Bosen installation consists of 6 furnaces grouped in pairs. A furnace consists of a metal part and a refractory masonry part. The metal part consists of a molded steel retort, in the form of 2 horizontal cylinders. In each cylinder is an app. for propulsion and mixing. The original feature is in the construction of cross-shaped (cruciform) shafts, divided into several sections working in a Cardan joint, some sections being fitted with blades carried by sleeves fixed on to the shafts, 4 blades forming a complete spiral. The propellers rotate in opposite directions, each blade being arranged to sweep the space between 2 adjacent blades, thereby preventing fouling of the app. and periodically drawing the material from the center of the retort toward the heated walls. The capacity of a retort is 10 to 12 cu. m. in 24 hrs. The time necessary for complete distn. is about 2 hrs. The normal temp. of distn. is 470° to 500°. The shale is crushed to pieces 0 to 33 mm. in size, the fines constituting about 60% of the charge. Temp. is controlled by elec. pyrometers in each retort. Gas produced by distn. is taken off by tubes, of large cross section, to a general collector, under a negative pressure of 5 mm. of water. The temp. in the combustion chamber is

const. at about 1300°. Heating of the producer has been provided for by means of metallurgical coke, with 79 to 80% free C and 6700 cal. Coke is consumed at the rate of 160–165 kg. per ton of shale distd. The furnaces built by the Soc. de Mines de l'Esterel are adapted for low-temp. carbonization of all bituminous combustibles rich in hydrocarbons and in particular those of glutinous nature for the following reasons: (1) Their continuous method permits treatment of a large tonnage with relatively few units; (2) they are particularly adapted to distil fine material; (3) the absolutely tight retort permits rational distn. without polymerization or pyrogenation of gaseous products; (4) all the hydrocarbons contained in the ore can be obtained with a max. of light fractions; (5) the propulsion and mixing app. while preventing the agglomeration of the matter, puts it in frequent contact with the heated walls of the retort and facilitates the liberation of gas; (6) all parts are interchangeable; (7) finally the construction of the furnaces themselves, with alternate means of operation, by stopping and putting back into operation, has made it possible to obtain highly satisfactory results. C. W. Owings

The Dvorkovitz process of low-temperature carbonization. David Brownlie. *Gas Age-Record* **62**, 354–6(1928).—An exptl. plant at Slough, near London, consisting of 2 retorts, each with a throughput of 5 tons of coal per 24 hrs., is described. The retorts are both internally and externally heated with producer gas. Yields of 30 gal. of low-temp. tar per ton and 75% of smokeless fuel, contg. less than 10% volatile matter from av. bituminous coal are claimed. On distn., 4 gal. of gasoline, 12 gal. of kerosene, 6 gal. of lubricating oil, 24 lb. of paraffin wax, 40 lb. of phenols, 90 lb. of residual pitch and 24 lb. of sulfate of ammonia are said to be obtained from the 30 gal. of tar. Leslie B. Bragg

The Plassmann process of low-temperature carbonization. David Brownlie. *Gas Age-Record* **62**, 196–8(1928).—The Plassmann retort is carefully described. It is an ingenious, mechanically continuous retort for the carbonization of bituminous coal dust and fines. From swelling coals, in consequence of the confinement and compression of the coal, large-sized pieces of coke are produced containing 8–12% volatile matter. A retort having a capacity of 50 tons of coal per 24 hrs. is now in operation at Essen, Germany. Leslie B. Bragg

The Lurgi carbonization process. F. A. Oetken and O. Hubmann. *Montan. Rundschau* **20**, 425–30(1928).—The Lurgi process of coking coals by a stream of hot gas passing directly through the ground coal merits attention because of its special value in carbonizing the younger fuels—lignites, cannels, torbanite, bituminous shales and peat. A description and schematic elevation drawing of a Lurgi installation are given. The fuel works down through a vertical retort structure composed of 3 directly connected chambers designated as drying, carbonizing and coke-cooling zones. Heating of the 2 upper zones is accomplished by circulating through them a portion of the hot circulating gas produced and when needed to maintain the desired temp. a portion of the gas is burned in heating ovens around zones 1 and 2. Advantages claimed for the Lurgi process are: large capacity of ovens, accurate control of working temps. from 450–500° for low- to 1000° for high-temp. carbonization, favorable heat exchange allowing a large throughput, simple, reliable and reasonable-priced construction, and sep. drying and carbonization of the fuel. Pictures are given of 2 plants constructed to process 120, and 500 tons/24 hrs. of brown coal; also of 25, and 360 tons/24 hrs. lignite plants. Results obtained in the 25t/24 hr. lignite and the 120t/24 hr. brown coal plants, of Al-retort carbonization assays, and analyses and properties of fuels used, the tar, light oil, and pitch and semi-coke produced are tabulated. Additional gas is needed if the material being carbonized contains over 45% water. 70 h. p. for mech. work and 3 shifts of 15 men are required to operate the 120t/24 hr. plant. The products obtained depend on the properties and kind of fuel being carbonized, but plant operations can be varied to produce more oil and tars or for more semi-coke or for av. yields of both kinds of products. W. W. Hodge

Combustion studies. Fritz Schuster. *Feuerungstech.* **16**, 54–6(1928).—S. presents a table whereby the O_2 corresponding to any given CO_2 content in the flue gas can be more readily calcd. Ernest W. Thiele

The automatic control of combustion for steam boilers. Heinrich Treitel. *Arch. Wärmewirt.* **9**, 249–55(1928).—T. discusses the possible arrangements for regulating fuel, air and water when the boiler load varies, and the requirements to be fulfilled by a control system. He describes briefly the Bailey, Smoot and Roučka systems, and then at length the *AEG-Askania control* for powd.-coal boilers. The line pressure regulates the coal flow; the coal flow regulates the air, which is corrected by the flue-gas CO_2. The furnace draft and the water level are separately regulated. The regulating element is a light pivoted arm delivering a jet of oil. The position of the arm

directs the jet into one of two holes, which lead to opposite ends of a cylinder. The piston accordingly moves with the arm. ERNEST W. THIELE

The reactivity of combustibles. Method of measurement of velocity of the propagation of the combustion. CH. QUILLARD. *Compt. rend.* **187**, 122–4(1928).—Under well regulated conditions the velocity of propagation for several fuels has been detd. Under-given conditions the rate of propagation in cm. per min. has been detd. for chips of wood, 0.60; anthracite, 0.75; charcoal from sugar, 1.60; semi-coke, 1.15; carbonite, 1.70; wood charcoal, 2.2 to 3.2. L. D. R.

Recent work on the petrology of brown coal. I. H. BODE. *Braunkohle* **27**, 459–64(1928).—A specimen from the Cologne district was investigated by general methods described. The usual disorganized ground mass, with inclusions of wood fragments, periderm, epidermis, spores, pollen, etc., was found, indicating thorough disorganization by atmospheric and other agencies before burial, the Gothan dry peat theory. Remains of wood-destroying fungi were found. F. S. GRANGER

Utilization of brown coals and bogheads of Irkutsk area, Siberia. V. I. MINAEV. *J. Chem. Ind.* (*Moscow*) **5**, 694–7(1928).—The value of the boghead and the brown coal deposits which are at about 200 km. from Irkutsk consists chiefly in the primary tar which can be obtained from them by distg. at 450–500° without access of air. The tar content of the coals is 25–30%, the residual coke being only 11.64%; the ash content of the coals is very high (27.7%). The primary tar, when free from secondary decompn. products, is a liquid bitumen contg. a high % of high-mol. satd. hydrocarbons very suitable for the *manuf. of viscous lubricating oils.* These deposits are not yet mined; if developed, they might yield 150,000 tons of mineral oils annually for 100 years. BERNARD NELSON

The problems of brown-coal distillation. P. ROSIN. *Brennstoff-Chem.* **9**, 182–4 (1928).—In 1926 441,000 tons of brown-coal coke was produced in Germany and this was mostly used for household heating, satisfying the demand for that purpose. In 1928 700,000 tons of coke has been produced and the problem of industrial utilization of the 300,000 tons excess now confronts the mfrs. With the increase in amt. of coal distd. other problems arise, such as: disposal of the poisonous distn. water, economic degree of pre-drying, utilization of dusty rotary-oven tars and economic utilization of distn. gas. J. D. DAVIS

Pressure hydrogenation of an Eozäu brown coal. J. VARGA. *Brennstoff-Chem.* **9**, 277–92(1928).—The coal (1.1% H_2O content and 9.05% low-temp. tar yield) was hydrogenated in a 3.73-l. bomb at 75, 100, and 125 atm. and 450 to 480°. Weights of samples were 300, 400 and 500 g. and heating time at the test temp. varied from 1 min. to 3 hrs. Because of the high S content of the coal (3.98%) 15% Fe_2O_3 was mixed with the coal, by which a S-free gas and oil contg. only 0.22% S were obtained. The Fe_2O_3 works not only as a desulfurizer but as a catalyzer; 5% suffices for the latter purpose, its function being to lower the temp. at which optimum H_2 absorption takes place. The coal yielded 16.8 to 57.9% oil of 1.002 to 1.066 sp. gr., the largest yield being obtained with heating time of 1 min. (after the test temp. was obtained). Longer heating cracked the oil, giving a smaller yield of lower boiling oil. The relative amt. of H_2 the temp., and heating time influence not only the amt. but also the properties of oils obtained. With 500 g. sample and 100 atm. initial pressure heating to 480° gave an oil yield of 52%. The best yield (57.9%) was obtained with 300 g. sample heated to 470° with 100 atm. initial pressure. J. D. DAVIS

Microstructure of New Zealand lignites. II. Lignites subjected to the influence of igneous intrusion. W. P. EVANS. *Fuel in Science & Practice* **7**, 402–7; *New Zealand J. Sci. Techn.* **9**, 339(1928); cf. *C. A.* **22**, 1305.—The various seams of the area studied (Broken River) were largely made up from small fragments of coniferous wood together with smaller quantities of leaves, stems and moss-like plants. This coal-forming mass appears to have been deposited in still water at some distance from the source of vegetation. The wood exhibits a closer relationship to *Taxus* than that shown by any living N. Z. taxads. Spores are rare. The mineral matter is partly distributed evenly throughout the coal mass and partly deposited in fissures. The large quantity of S carried by the unaltered lignite is chiefly org. D. A. REYNOLDS

Drying, carbonization and distillation of peat. CHARLES A. ROUX. *Mon. produits chim.* **9**, No. 90, 8–12; *Chem. Zentr.* **1927**, II, 768.—The equipment and procedure are described for the complete working up of peats of every sort from its removal from the bog to the prepn. of *coke, tar oils, paraffin, pitch, NH_3* etc. with the utilization of all by-products. J. S. REICHERT

Examination of decayed oak. Remarks on the Fischer-Schrader coalification theory. A. BRANDL. *Brennstoff-Chem.* **9**, 89–94(1928).—Oak mold is subjected to the

alkali-acid extn. analysis of S. Odén (*C. A.* **20**, 3342) and also to the acetyl bromide-HCl extn. method of Karrer (*C. A.* **18**, 80). The last method gave: Hydrolyzable matter 25.99% (of this 9.3% was cellulose), lignin and lignin acids 36.72% and humic acids 37.29%. The 2 methods gave closely agreeing results. Ultimate analyses are made and groups COOH and OCH_3 are detd. Results indicate the predominance of lignin either as such or as its solid decompn. products (humic substances). Cellulosic matter seems to have been converted by fungi and bacteria into gases and H_2O-sol. decompn. products which cannot have contributed materially to the solid matter of coal. J. D. Davis

Some technical and economic aspects of the by-product ammonia recovery problem. P. Parrish. *Gas J.* **183**, 677–9(1928).—The production of a concd. gas or sulfate liquor for transport to a central plant, within a radius of 40 miles, for final treatment, is advocated. Disadvantages of the so-called direct and semi-direct processes, in which aq. condensation, before the saturator, is prevented or minimized, are pointed out. Prominent among these are corrosion from HCl liberated by carrying NH_4Cl over into the saturator, diln. of the bath and unsatisfactory nature of the tar. The large no. of operations involved in the anhydrite process, in which $CaSO_4$ is used as a source of SO_3, are not generally realized, and feasibility of this process is largely dependent upon geographical position with reference to anhydrite mines and upon the scale of operations. The utilization of the $CaSO_4$, resulting from treatment of phosphate rock, instead of anhydrite, is deemed worthy of study. Also in *Chem. Age* (London) **19**, 280–2(1928). F. S. Granger

Gasification of steam-dried Köflacher coal in rotating-grate generators. Ludwig A. Richter. *Braunkohle* **27**, 850–7(1928).—Steam-dried lignitic coal, such as the Köflacher coal, as opposed to raw coal as well as to geologically older coals, presents great advantages for gasification purposes. This results primarily from the favorable compn. of the gas, with a calorific value of 1500–1550 kg.-cal. for the water-free and tar-free gas and 1650–1700 kg.-cal. for dry tar-contg. gas. This gas compn. is brought about by the high reactivity of the coal substance, as a result of which the decompn. of the steam takes place to a greater extent, and by a higher content of volatile constituents. Further advantages are the favorable nature of the ash and the low S content. The m. p. of the ash is rather high, namely 1280–1300°. Clinker formation, therefore, does not enter in and less steam is required. The water content is, as a result of the drying and the increased steam decompn., lower than with other coals. There are no tendencies toward caking or falling to pieces at high temp., so coking of any kind can be dispensed with. Top fire and periphery fire also cannot occur, for the same reason. The favorable properties of the cinders and of the coal make it possible to work with a deeper ash and coal bed, resulting in small loss from unconsumed coal in the ashes and lower gas temps. Both circumstances unite with the favorable gas compn. in raising the efficiency. The steam generated by the coal itself, in drying, may be utilized for gasifying it. The capacity of the generator is extraordinarily high, corresponding to 1.8×10^6 kg.-cal. of coal heat or 350 kg. of coal per sq. m. cross section per hr. This combines with the elimination of coking, the small ash work and the high efficiency to cheapen the installation, operating and labor costs in using dried coal. Because of the high ash m. p. and low S content, the coal is adapted as a mixing coal to meet the difficulties due to clinker and gas S content in metallurgical firing. The argument is supported by practical data. F. S. Granger

The complete gasification of coal for town's gas. Morris Travers. *J. Soc. Chem. Ind.* **47**, 203–10T, 213–9T(1928); cf. *C. A.* **18**, 161; **19**, 1044, 3157.—The principles on which this complete coal-gasification system operates is explained by comparing it with the gas producer, and contrasting it with the water-gas plant operated with bituminous coal. Descriptions, diagrammatic drawings, and methods of operation are given of a simply modified water-gas generator, of the first plant erected (capacity 250,000 cu. ft. of 350 B. t. u. gas/24 hrs.) for the complete gasification of coal, and of the new plant built to produce up to 1,000,000 cu. ft./24 hrs. including carbureting gas to increase its thermal value to 400 B. t. u./cu. ft. The chem. reactions, thermal analyses and theories of the different systems are discussed. The difficulties encountered in operation and in design especially in going from the 250,000 to the 1,000,000 cu. ft./24-hr. plant are described, also the means employed to secure smooth working and full output. The results of expts. to det. the effect of size and stirring in using bituminous coal as generator fuel showed an advantage was gained by agitating the top layers of the fuel bed if the coal contained a considerable amt. of small material. Drawings are given of 4 different types of coal stirrers and their relative advantages are outlined. Results of several test runs of the different plants are given. In one

test extending through 8 shifts 53.21 tons of dry coal and 2838 gals. of oil were used to produce 2,605,000 cu. ft. of gas of approx. 445 B. t. u./cu. ft. The coal made 2,406,350 cu. ft. of the total gas vol. and this uncarbureted gas had a calorific value of 363 B. t. u./cu. ft. This is equiv. to 174.2 therms per ton of dry coal with no allowance made for coke recovered from the generator. The essential difference between the complete gasification plant and the water-gas plant resides in the arrangement for heating the coal regeneratively by means of water-gas and the circulation gas. Part of the sensible heat of the water-gas is utilized by passing it through the coal. The steam consumption in one test was rather large. A no. of analyses of the gases produced are tabulated; one example where samples of circulation gas and of carbureted gas were taken simultaneously is resp., CO_2 4.6%, 3.1%; CO 32.6%, 32.1%; CH_4 7.9%, 14.4%; C_mH_n 0.6%, 5.1%; H_2 47.8%, 39.7%; N_2 6.5%, 5.6%; calorific value 362.4, 507.4 B. t. u./cu. ft. Several thermal calcns. are given and data obtained from the large plant at Harrow indicate that carbonization in the complete gasification plant operates economically and efficiently. W. W. Hodge

Organic sulfur content of coke-oven gas from coals of widely varying sulfur content. O. P. Brysch and J. F. Byrne. Koppers Co. Lab., Pittsburgh. *Proc. Am. Gas Assoc.* **1927**, 1463–71.—Seven coals and coal mixts. of different S concn. were carbonized in a Becker oven under identical conditions, and the org. S concn. of the gas was detd. by the referee S-app. With 2 exceptions, all showed the org. S of the gas to be approx. directly proportional to the % S in the coal, there being 20 grains of org. S in the gas for each % S in the coal. This direct proportion may possibly not be valid for the carbonization of all types of coals or their mixts. When 2 high-S coals were mixed with Pocahontas coal and carbonized, there were obtained a gas of greatly reduced org.-S concn. and a lower-S coke compared with the results when the coals were carbonized alone. 75–90% of the org. S is evolved at the end of the 8th hr. of the regular 12-hr. coking operation. Pocahontas coal seems to accelerate the evolution of org. S from the high-S coals. The S in the coke (expressed as % of total S in the coal used), possesses the same trend as the org. S in the gas. A S-balance on a mixt. of Kentucky (high volatile) and 20% Pocahontas shows that 59.4% of total S charged is retained by the coke, 1.4% passes over as org. S in the gas, 27.4% as H_2S and 11.8% as S in the tar and NH_3 liquor. J. H. Perry

Gas manufacture. J. W. Cobb. *Gas J.* **183,** 670–1(1928).—A discussion of some current problems from the economic standpoint. F. S. Granger

Device for measuring the rate of flow of gases at the Chemical Research Institute in Warsaw. A. Kaczorowski. Chem. Research Inst. (Warsaw). *Przemysl Chem.* **12,** 294–9(1928).—An app. was assembled for standardizing gas-flow meters for natural gas. A. C. Z.

Specific heat of gases. M. Y. Lourier (Lur'e). *Izvestiya Teplotekh. Inst.* (*Bull. Inst. Fuel Research* (*Russia*)) **1926,** No. 1, 5–31.—Critical review on work done by 82 investigators during the years 1687–1925. A. A. Boehtlingk

Prevention of danger in the operation of gas generators. Kattentidt. *Zentr. Gewerbehyg. Unfallverhüt.* **14,** 202–5; *Chem. Zentr.* **1927,** II, 996.—K. describes a number of devices, as explosion and other safety valves. They are intended to let escape safely into the open air the explosive pressure caused by explosions in the air line of generators operated with compressed air, explosions that frequently occur at a sudden stop of the blast app. on account of backward motion of the gas. Some accidents are described that were caused through the failure of the devices to work, or through carelessness of the laborers. The rare occurrence of a 2nd explosion 10 min. after the 1st one is discussed. G. Schwoch

Laboratory results on the removal of organic sulfur from gas. Norman F. Prince. Rochester Gas and Electric Corp., Rochester, N. Y. *Proc. Am. Gas. Assocn.* **1927,** 1441–52.—Mixed gas purified by passing through 2 wash bottles of 5% Na_2CO_3 and 2 bottles of 5% $CdCl_2$, was passed through 2 or 4 bottles contg. aniline soln., and thence through the tower to remove org. S. The tower (45 in. long and 1 in. in diam.) was filled with glass wool which contained flowers of S. The gas, passing counter-current to the aniline at $^1/_3$ cu. ft./hr., was then passed through 2 bottles of 5% $CdCl_2$, thence through a meter to a Jenkins S app. The results were:

Scrubbing Medium	S in Gas (Grains/100 cu. ft.) Inlet	Exit	% Removal	Temp. °F.
Satd. aniline-H_2O	10.3	9.2	10.7	69
40% NaOH-excess aniline	11.4	6.6	42.1	74
20% NaOH-excess aniline	13.9	3.9	71.2	77
10% NaOH-excess aniline	17.8	7.3	59.0	62

Plain gas oil scrubbing of ordinary mixed gas with a double Bird scrubber (*C. A.* 14, 2254) gave the following results with 3000 cc. fresh gas oil:

S in Mixed Gas (Grains/100 cu. ft.) Inlet	Exit	% Removal	Gas Flow cu. ft./hr.	Time of Run (hrs.)
13.40	6.56	51.04	6.1	1.16
11.82	7.04	40.04	3.8	
11.88	8.43	29.00	5.3	1.50
10.53	8.63	18.00	3.9	1.33
11.92	10.04	15.80	4.2	1.5
11.15	8.76	21.40	4.1	1.33
12.42	11.09	10.70	3.3	1.50

The temp. of each run was 80° F. The following expts. were made with mixts. of 2800 cc. gas oil—5% aniline, 0.5% S and some NaOH, in a double Bird scrubber:

S in Mixed Gas (Grains/100 cu. ft.) Inlet	Exit	% Removal	Time of Run (hrs.)	Gas Flow cu. ft./hr.
11.02	6.82	38.10	1.5	5.6
10.87	5.90	45.70	1.66	2.5
8.66	5.53	36.10	1.50	2.4
11.53	5.81	49.60	1.50	2.3
11.36	6.12	46.10	1.50	2.5
11.36	5.61	50.60	1.50	4.9

The temp. of each run was 80° F. The addition of the aniline, S and NaOH, therefore, gave a more const. rate of S removal. Since this thiocarbanilide reaction results in a better and more uniform S removal, the efficiency of a tower method of scrubbing was studied. The tower was of glass, 48 in. high and 2 in. in diam., and filled with 1/4-in. coke. The oil entered the top of the tower and was recirculated with a pump; the mixed gas entering the bottom of the tower. The scrubbing medium was: 3300 cc. gas oil, 250 cc. aniline, 65 g. S, 10 g. I and some NaOH. The following tests were made:

S in Mixed Gas (Grains/100 cu. ft.) Inlet	Exit	% Removal	Time of Run (hrs.)	Gas Flow cu. ft./hr.	Temp. ° F.
11.56	5.08	56.10	1.25	5.4	77
10.77	4.71	56.30	1.67	5.3	77
10.13	5.07	50.00	1.25	5.8	77
9.64	6.21	35.60	1.42	6.8	77
10.22	5.41	47.10	1.75	5.2	77

Tests made to show the effect of temp. on the scrubbing indicated that an increase of temp. causes a decrease in the S removal. J. H. PERRY

Absorption of sulfur dioxide in the Orsat apparatus. L. K. RAMZIN. *Izvestiya Teplotekh. Inst.* (*Bull. Inst. Fuel Research* (*Russia*)) **1926**, No. 1, 51–5.—R. disagrees with the prevailing opinion that SO_2 gases are dissolved in the condensate obtained from flue gases after cooling down. Only 0.25–2.0% of the total amt. of SO_2 is held by the condensate; the balance enters the Orsat app. and is absorbed by the KOH soln. together with CO_2, giving too high values for the CO_2. A. A. BOEHTLINGK

Résumé of recent literature on carbon disulfide with reference to the gas industry. JOHN C. HOLTZ AND WILBERT J. HUFF. Johns Hopkins Univ. *Proc. Am. Gas Assocn.* **1927**, 1436–9.—References are given to the recent literature concerning: detection and estn. of CS_2; CS_2 in gas making; removal of CS_2; production of CS_2; and the equil. between C and S in the formation of CS_2. J. H. PERRY

The origin and decomposition of carbon disulfide in gas making. II. The carbon-sulfur complex. WILBERT J. HUFF AND JOHN C. HOLTZ. Johns Hopkins Univ., Baltimore, Md. *Proc. Am. Gas Assoc.* **1927**, 1431–5; cf. *C. A.* **22**, 1228.—The formation of CS_2 during oil cracking is of particular interest because the S compds. are probably uniformly dissolved in the remaining oil constituents, thus affording a homogeneous system in contrast to the heterogeneous system in the case of coal previously studied. By feeding a high-S gas oil, into the top of an ordinary quartz cracking tube, at a rate of about 2 cc. per 5 min., the gas was passed through a tar trap and a cotton tar filter tube into a gasometer. The resulting gas sample was then analyzed (cf. *C. A.* **20**, 1508). A cracking temp. of 1200° F. gave too little CS_2 to be detd. in a 2-l. gas sample by the cupric xanthate method; at 1350° F. a definite ppt. was obtained, and at 1800° F. very heavy ppts. were obtained. H_2S may be converted to CS_2 under certain cracking conditions. It is suggested that C surfaces, when exposed to S-contg. gases at

temps. used in gas making, at first absorb S from those gases, which assists in the decompn. of the S compds. The ability to absorb S in this way decreases the exposed C surfaces, satn. is approached and finally CS_2 is evolved. The decrease of the tendency of heated refractory surfaces to decompose S compds. in gas is due not merely to the presence of C upon the surface but rather to the gradual formation of a C-S complex. That C-contg. surfaces free from a complex S condition possess a property similar to that of clean pumice was shown by using a coke cartridge, purged with H_2 at a high temp., in place of the pumice, wherein no CS_2 was found at 1350° F. With continued use, CS_2 ultimately is formed, however. This delay in CS_2 formation cannot be explained by the assumption of external temp. changes, but the delayed formation of the appropriate C-S complex may partly explain the delayed formation of CS_2 over cracking surfaces noted in the operation of carbureted-water-gas plants by Klein (*C. A.* **17**, 1707). With increasing cracking temps., the dissocn. of H_2S and other S-contg. compds. increases, as well as the deposition of C. At higher temps. in gas-making processes it is to be expected that the rate of formation of the C-S complex may be rapid. This would explain the very rapid production of CS_2 from a rapidly formed complex when a S-contg. oil or coal is suddenly thrown on to a very hot surface. The C-S complex plays an important, if not exclusive, part in the formation of CS_2. Conditions favoring the fixation of high local S concn., such as sudden heating with decreased diffusion, reduction of exposed surfaces, and the rapid removal of formed CS_2, also favor the presence of CS_2. Any process giving the gas extended contact with heated surfaces sufficiently low in, or free from S, will decrease the concn. of CS_2 in the gas, or eliminate it entirely. There is at present no evidence to show that CS_2 is produced by a simple reaction between H_2S and C. While S appears to resemble O_2 in forming a complex with C, no exact analog of CO has been isolated. A list of S compds. found in tar oils, with literature references is included.

J. H. Perry

Laboratory apparatus for control of the hydrogen sulfide content of gas. Anon. Municipal Gasworks Utrecht. *Het Gas* **48**, 281(1928).—Gas flows through a glycerol wash bottle and a thermometer capillary on to a continuously moving strip of filter-paper, moistened by a wick with $Pb(OAc)_2$ soln. A continuous record is thus obtained.

An estimation of the accuracy of the Morehead gas apparatus. H. L. Olin and W. G. Ingram. Univ. of Iowa. *Gas Age-Record* **62**, 445–7(1928).—Results obtained by the use of the Morehead app. have been compared with those given by the Burrell-Orsat app. It was found that the values obtained with the Morehead app. were: for CO_2 about 1.1% high, for illuminants 1.8% low, O_2 1.5% high, CO 0.7% low, H_2 7.3% low, CH_4 0.9% high, C_2H_6 no detn., N_2 7.9% high; the above figures are % of total gas and not % error.

Leslie B. Bragg

The use of after-coolers with high-pressure gas compressors. J. E. Cooper. *Gas Age-Record* **62**, 199–200(1928).—The after-cooler installation at the Utica Gas & Electric Co., Utica, N. Y., is described. By cooling the compressed gas to 70° F. in the summer and to 40° F. in the winter they have succeeded in preventing all condensation in the line.

Leslie B. Bragg

The gas smithy of the railroad shops in Arnsberg. Pontani. *Arch. Wärmewirt.* **6**, 105–10(1925).—Cold, clean, brown-coal producer gas is used. The gas and air *recuperators*, of *iron pipe coil*, set in chambers well-protected from furnace radiation, heat the gas and air to 500°.

Ernest W. Thiele

Résumé of work done at the Liévin experimental station from 1912 to 1914 on combustion of gaseous mixtures. G. Le Floch. *Rev. ind. min.* **1928**, No. 175, 143–57.—One of the problems was the *detn. of ignition temp. and the lag of ignition.* Mixts. of gases are introduced into a bottle in an elec. furnace and a photographic manometer photographs the flame while a chronograph records the time. The lag in ignition of H is several seconds but the zone of the long lags is very narrow and limited to several degrees. The lag of ignition of CH_4 for an 8% mixt. is about 0.8 sec. at 700° and 0.1 sec. at 900°; for a 72% mixt. about 6 sec. at 700°; ignition is nearly instantaneous at 1000°. Benzine in a 2% mixt. ignites at 600° in about 0.4 sec. but does not ignite below this temp.; at 800° ignition is nearly instantaneous; a 10% mixt. ignites at 700° in about 1.5 sec.; C_2H_2 ignites at about 540° in from $^1/_2$ to 1 sec. and C_2H_6 in proportions of 4% and 6% ignites in 6 sec.; a 2% mixt. of toluene ignites in about

8 sec. at 600° and in about 0.2 sec. at 800°. These values are taken from charts prepd. from results of tests. A study of variation of the limit of ignition with temp., pressure and compn. of a gaseous mixt. shows that for CH_4 the curve for variation with temp. is a straight line, ranging from 6% CH_4 at 0° temp. to practically 3% CH_4 at 700° temp. The inflammability of CH_4 varies with the content. With about 13.9% O the CH_4 content necessary for ignition is from about 6.2 to 7.7%. The curve is a straight line for ignition from 7.8% CH_4 and 14% O, to 12% CH_4 and 17.5% O. Another subject studied was the *detn. of the rate of combustion of gaseous mixts.* at different temps. At 15° the rate of combustion of CH_4 is 30 cm. per sec. with a 7% mixt., the rate increasing to 70 cm. per sec. at 9.3% CH_4 and then decreasing to 30 cm. per sec. at 11.75% CH_4. The detn. of the rate of combustion allows calcn. of the rate of reaction to corresponding temp. of combustion. Data of tests made on the propagation of the explosive wave in gaseous mixts. are incomplete, as many records were lost during the World War.
C. W. O.

Removal of carbon dioxide from industrial gases with alkali carbonates at normal pressures. F. FISCHER AND P. DILTHEY. *Brennstoff-Chem.* **9**, 138–44(1928).—The feasibility of removal of CO_2 from gases with alkali carbonates is thoroughly investigated. The best results are obtained with hot solns. and these were best regenerated with warm air. The best absorption temp. was 70–80°; that for regeneration was 90–95°. Absorption data are given for various carbonate concentrates, various tower fillings and temps. J. D. DAVIS

Natural gas. K. STOCKFISCH. Prussian State Geol. Inst., Berlin. *Z. angew. Chem.* **41**, 472–5(1928).—S. presents a tabulation of the published analyses of the compn. of natural gas from various sources in Germany, and discusses somewhat the probable origin of the gases high in N_2. G. CALINGAERT

Natural gases. II. Helium content of the natural gases of Poland. KAZIMIERZ KLING AND LECH SUCHOWIAK. Jan Kazimir Univ. Lwow. *Przemysl Chem.* **11**, 209–42 (1927).—Samples drawn from the Carpathian fields of Boryslaw-Tustanowice, Bitkow, Daszawa and Krosno-Jaslo all showed the presence of He, but clearly below 0.05%. Tabulated results indicate that He content of gases of Sub-Carpathian fields increases in the easterly direction. A. C. ZACHLIN

The possible chemical utilization of methane, with special reference to natural gas. A. W. NASH AND H. M. STANLEY. Univ. of Birmingham, Eng. *Fuel in Science & Practice* **7**, 397–401(1928).—In considering the various possibilities of its chem. utilization a survey of the present knowledge of the properties of CH_4 is made. Its chlorination, oxidation, thermal decompn., reaction with steam and conversion into higher hydrocarbons are discussed. The authors believe that the solution of this problem lies within the range of high-pressure and high-temp. reactions, which are now imperfectly known. D. A. REYNOLDS

The purification of coal gas. CHARLES COOPER. *Gas J.* **183**, 671–7(1928).—Detailed review of current industrial practice, with bibliography. F. S. GRANGER

A study of flue-gas analyses. FRED M. REITER. Dayton Power & Light Co. *Gas Age-Record* **62**, 437–8, 452(1928).—The effect of H in the fuel and excess air on flue-gas analyses is discussed. Stoichiometric calcn. of the flue gas, as a means of checking the analysis, and possible errors in sampling and analysis are also considered.
LESLIE B. BRAGG

False readings of flue-gas testers. FICKERT. *Arch. Wärmewirt.* **9**, 124(1928).—In CO_2 meters depending on heat cond., the presence of H_2, due to its high cond., causes an abnormally low CO_2 reading. Such meters cannot be relied on unless means of measuring combustibles are also provided. ERNEST W. THIELE

Basic equations for a complete combustion of flue gases. L. K. RAMZIN. *Izvestiya Teplotekh. Inst.* (*Bull. Inst. Fuel Research* (*Russia*)) **1926**, No. 1, 32–50.—The following calcns. are made: vol. of gases, influence of SO_2, air excess factor, change in vol. on combustion, sp. heat and the heat content of flue gases, av. volumetric sp. heats of flue gases at const. pressure and wt. of flue gases. A. A. BOEHTLINGK

High-grade producer gas from low-grade fuels. RUDOLF CZERNY. *Feuerungstech.* **15**, 337–42(1927).—To increase the heating value and flame temp. of the gas from a poor fuel, part of the gas may be cleaned, heated with a still lower-grade fuel, and introduced into the producer at the lower end of the carbonization zone. Detailed calcns. show that in this way the heating value may be raised from 1386 to 1548 kg. cal. per cu. m., the flame temp. rising 75° or 100°. With a deep fuel bed these figures may be slightly improved. The efficiency is lower by the change, but the use of a cheaper fuel makes the economy about the same. ERNEST W. THIELE

The purification of producer gas. F. BÖSNER. *Z. oesterr. Ver. Gas-Wasserfach.*

68, 139–44(1928).—A description of the elec. pptn. and filtration equipment used for purifying producer gas in the bayrischen und oesterreichischen Vereines von Gas und Wasserfachmännern in Graz. J. H. PERRY

Enameling furnaces with producer-gas firing. G. KÖRRN. *Keram. Rund.* **36**, 221–3(1928).—A construction of gas channels is described which permits removal of tar without interruption of operation of the producer. At the lowest part of the gas channel a sump is provided with one or more pipes of suitable size through which the tar flows to a large reservoir with its bottom at a lower level than the sump. Tar may be removed from the larger reservoir through an opening above. H. INSLEY

The utilization of coke-oven gas by the gas industry. T. P. RIDLEY. *Gas J.* **183**, 659–62(1928).—A general discussion. F. S. GRANGER

The possibilities of vapor-phase oil gas. THOMAS F. HINTZE. Lapp Products Corp. *Gas Age-Record* **62**, 394(1928).—Vapor-phase oil gas is produced by a progressive heat distn., using very high vapor velocities, at times above 40,000 cu ft. per min. The vapor is heated in a heat zone from 230° to 760°, under which conditions benzene and toluene are produced. Low-grade crudes can be converted into gas of 600 to 1500 B. t. u. per cu. ft. LESLIE B. BRAGG

Manufacture of water gas of low specific gravity. LOUIS STEIN AND L. J. WILLIEN. *Chem. Met. Eng.* **34**, 676–7(1927).—By introducing about 1.5 gals. of oil per M into the top of the superheater during the backrun stage of a water-gas set (coke fuel) a 550 B. t. u. water gas was made of sp. gr. 0.50 to 0.55, which could successfully be substituted for straight coke-oven gas (St. Paul). The capacity of the machine was increased 25% over its normal value. This procedure is believed to be of practical value during peak loads. B. J. C. VAN DER HOEVEN

Possibilities of increasing the capacity of producers and water-gas generators. J. GWOSDZ. *Brennstoff-Chem.* **9**, 184–8(1928).—A critic of various proposed methods for increasing capacity; *i. e.*, gasification under pressure, the slagging method, gasification of fine sizes and pulverized fuels. A method involving gasification of fine sizes in rapid motion is being experimented with by the I. G. Farbenind. A.-G. This affects intimate contact of reacting gases with the fuel and holds out promising possibilities. J. D. DAVIS

An investigation of checkerbrick for carbureters of water-gas machines. CULLEN W. PARMELEE, ALBERT E. R. WESTMAN AND WILBUR H. PFEIFFER. Univ. Ill. Eng. Expt. Sta., *Bull.* **179**, 88 pp.(1928).—This investigation covered a study of the phys. and chem. properties of a number of brands of firebrick, the effects of reducing gases, steam and temp. fluctuations on their durability, and the significance of the black cores found in the used bricks. Service tests were also made of samples of each brand in carbureters of different types. The conclusions were that the primary cause of shut-downs was not the failure of the checkerbrick but the deposition of asphalt-like material in the carbureters due to the use of low-grade enriching oils. Under the operating conditions investigated fireclay bricks as a class were unsuited for use in the top courses of carbureters where they quickly fail because of cracking due to stresses set up by the quenching action of the oil on the hot brick. Deposition of C in the pores of the brick, the presence of steam in high concns., surface deterioration due to attack by slag and coke breeze and Fe content of the brick were all found to be minor causes of failure. In general the use of semi-flint clay or the addn. of grog or flint clay improved the service rendered by stiff-mud bricks. A checkerwork consisting of 12 courses of firebrick, 3 courses of bonded SiC brick and 2 courses of heat-resisting alloys would cost 19 times as much as one constructed of firebrick alone but it would last 15 times as long and would probably be more economical because of elimination of shut-downs, decrease of labor costs, and increase in capacity of plant. H. L. OLIN

Reply to the criticism of Hans Tropsch of my paper on the equilibrium conditions for formation of hydrocarbons and alcohols from water gas. D. F. SMITH. *Brennstoff-Chem.* **9**, 248–9(1928).—Polemical, dealing with equil. consts. calcd. by Smith and Tropsch (*C. A.* **21**, 2783; **22**, 3976). Smith's conclusion "at all temps. in increasing measure it is easier to obtain the higher hydrocarbons from water gas" is attacked by T. S. further explains his data and T. adds further comment. **Comment on the foregoing discussion by D. F. Smith.** H. TROPSCH. *Ibid* 250. J. D. DAVIS

New method of naphthalene determination. K. N. CUNDALL. *Gas Age-Record* **62**, 393–4, 402(1928).—The naphthalene is first removed from the gas by the Colman-Smith method of bubbling the gas through picric acid, forming naphthalene picrate. The ppt. is then filtered out and very carefully washed with a 0.20% picric acid soln. The filter paper and ppt. are next dried with a filter pump until all possible wash solution has been removed and the ppt. appears dry. An excess of a soln. made by dissolving

188 g. of KI and 24 g. of KIO_3 in 500 cc. of cold distd. water is added; this breaks down the naphthalene picrate, liberating picric acid, which in turn reacts with the KI and KIO_3 to liberate a quant. amt. of I. The I is titrated with $Na_2S_2O_3$, a 0.1 *N* soln. being used with starch as indicator. One mol. wt. of $Na_2S_2O_3$ corresponds to 1 mol. wt. of naphthalene. The picric acid retained in the ppt. and the filter paper is estd. or detd. by a blank. LESLIE B. BRAGG

Factors affecting the determination of naphthalene by picric acid. A. R. POWELL. Koppers Co., Chicago. *Proc. Am. Gas Assocn.* **1927**, 1421–30.—Some of the fundamental conditions which influence the pptn. of naphthalene picrate are pointed out. The conclusions given are applicable to all naphthalene pptns. with picric acid. The app. consists of seven 8-oz. wide-mouth bottles with stoppers contg. the usual inlet and exit tubes. These bottles are, in their order: 5% H_2SO_4; empty; the following four contain exactly 100 cc. of standard 0.05 *N* picric acid; and the last bottle is empty and serves as a trap for picric acid. The sample line to this train and the first 3 bottles are kept warm to prevent sepn. of naphthalene. The av. gas sample of 20–25 cu. ft. is passed through the app. at about 5 cu. ft. per hr. The picric acid soln. is then transferred to a 500-cc. graduated flask, and this is filled to the mark with rinsings of the bottle. The soln. is filtered, and the first 50 cc. is rejected. 100 cc. of filtrate is titrated with 0.1 *N* NaOH. The grains of naphthalene per 100 cu. ft. is equal to: $(0.0128 \times 1543 \times C)$/cu. ft. gas sample, where $C = 4A - 5B$, and A and B are the cc. 0.1 *N* NaOH required for 100 cc. of the original and final picric acid solns., resp. The rate of gas flow should not be more than 5 cu. ft./hour. It is very important to have the picric acid soln. as concd. as possible, with due regard for the satn. temp. The temp. of the train should be between 65° and 80° F., the ideal temp. being just above the satn. point of the picric acid soln. used. NH_3 in the gas will make the analysis high; its presence is obviated by the H_2SO_4 wash bottle. There is no rapid routine method for the sepn. of naphthalene and gum-forming constituents. SO_2 will cause low analyses; it is therefore important in such cases to insert a wash bottle of weak alkali in the train. H_2S and CO_2 have no appreciable effect on the naphthalene detn. when methyl red is used as indicator. J. H. PERRY

The effect of indene on the determination of naphthalene by picric acid. W. H. FULWEILER, C. W. JORDAN AND A. L. WARD. U. G. I. Contracting Co. Lab., Philadelphia. *Proc. Am. Gas Assocn.* **1927**, 1418–21.—The methods of Brown and Berger (*C. A.* **18**, 3266) were used for the detn. of naphthalene and indene in 3 types of gases, coal, mixed and water gases; the precision is greater than that observed by Brown, but values are still high. With pure naphthalene, the method gave an av. of 108% of the naphthalene used. Brown's finding that there is an error in the titration method due to the pptn. of indene picrate is confirmed but the errors are smaller than those observed by B. In the concns. normally present in city gas, indene is not pptd. by picric acid. If there is present in the picric acid soln. a large amt. of naphthalene picrate, unsatd. hydrocarbons (indene, etc.) are either adsorbed or absorbed and some of the unsatd. hydrocarbons, probably indene, do ppt. or react with picric acid. Until some sp. method for the detn. of either naphthalene or indene is available, it will be difficult to det. the exact error of the usual titration method for naphthalene. The bridge method for the detn. of naphthalene is not affected by the presence of indene in amts. up to 50 grains per 100 cu. ft., and where the atm. of naphthalene detd. is 2 grains or more per 100 cu. ft. J. H. PERRY

A new glass receiver for determination of benzene and benzines with active carbon. A. WEINDEL. *Brennstoff-Chem.* **9**, 234(1928).—The app. consists of a previously described (*C. A.* **21**, 3120) graduated glass U tube in which the condensate steamed out of the active C is caught and sepd. into oil and water. Two changes are made in the design: (1) A side tube is welded into the receiving limb of the U at a point above the liquid level. A tube of active char connected to this serves to retain all light uncondensable vapors. (2) The condensate drops into a small funnel with capillary stem in the receiving limb, whereby, owing to surface tension effects, a sharp sepn. of oil and H_2O is effected. J. D. DAVIS

"Gas benzine" of the Gelsenkirchener Bergwerks-A.-G. tar works. F. KROLLPFEIFFER AND H. SEEBAUM. *J. prakt. Chem.* **119**, 131–56(1928).—The "gas benzine," the volatile fraction condensed after the sepn. of the tar, after treatment with alkali, yielded the following fractions on repeated distn.: (1) b. 33–36° (2.9%), contg. a C_5H_{12} and 2-pentene, (2) 36–40° (1.5%) contg. n-C_5H_{12} and Me_2C:CHMe, (3) 63–67° (4%), contg. $Me_2CH(CH_2)_2Me$ and hexene, (4) 67–70° (4.2%) contg. n-C_6H_{14} and $Me_2C=CH$-CH_2Me (the latter was synthesized by the elimination of H_2O from $Me_2C(OH)Pr$ and from EtCH(OH)CHMe$_2$), (5) 79–82° (1.6%), contg. a mixt. of C_6H_{14} and C_7H_{16} (?)

and C_6H_6. In addn., the presence of cyclopentadiene (identified as dimethylfulvene) in fraction (2), of CS_2 in the fraction of b. p. 40–50°, of MeCOEt, and of minute amts. of Me_2CO in practically all of the fractions, was demonstrated. The phys. consts. of the isolated hydrocarbons are recorded. B. C. A.

The quantitative determination of loss of organic solvents on extraction of water solutions. A. Weindel. *Brennstoff-Chem.* **9,** 213–5(1928).—The method given applies particularly to *detn. of C_6H_6 losses* (by soln. and emulsification) *during extn. of phenols from still waste.* A cylindrical iron container holding 30 l. provided with large inlet and outlet pipes with valves is inserted directly into the discharge line of the C_6H_6 washer for taking the sample. The entire waste stream is sent through this container for several min., then by-passed. The container is disconnected and allowed to stand until any emulsion present rises to the top, leaving a clear soln. at the bottom. This is drawn off and set aside. The C_6H_6 is distd. directly from the large container with steam, condensed and caught in a U receiver, where it is sepd. from the H_2O and measured. The clear soln. is returned to the large container and likewise distd., the C_6H_6 obtained being added to that first recovered. A guard tube filled with active char connected to the intake side of the receiver retains any C_6H_6 that is not condensed. Important features of the method are the large sample and the method of taking it. Small samples were not found representative. J. D. D.

Modern distillation of tar and of naphthalene. Vittorio Molinari. Instituto di Chimica G. Ronzoni, Milano. *Giorn. chim. ind. applicata* **10,** 357–63(1928).—Various continuous systems for the distn. of tar are described, with particular reference to those of Borrmann and of Raschig, which are discussed in detail with illustrations and diagrams. The *purification of crude naphthalene* may be carried out in much the same way. The Sipe plant at Cengio is described (with a diagram), in which the crude naphthalene is distd. *in vacuo* by a continuous process. The naphthalene is condensed at 85°, *i. e.*, above its m. p., by a circulation of hot water and the process is economically superior to processes hitherto in use for purifying naphthalene. The naphthalene is sufficiently pure for direct use in the *manuf. of H acid, α-naphthylamine, β-naphthol and phthalic anhydride for the manuf. of dyes.* C. C. Davis

Description and operation of a tar-distillation plant with horizontal stills according to the patented Weickel system for continuous and discontinuous operation. W. Karsten. *Teer u. Bitumen* **26,** 433–6(1928); cf. *C. A.* **22,** 3035. F. S. Granger

Estimation of the consistency of tar by means of the E. P. C. consistometer. Joseph Malette. École Nationale des Ponts et Chaussées. *Chimie et industrie* **Special No.,** 434–5(April, 1928).—The app. consists essentially of a hollow rod weighted at one end, which is allowed to sink into the tar at 18°. The time required to sink a given distance, as measured by two marks on the rod, is measured with a stop-watch and gives a measure of the consistency of the tar. A. Papineau-Couture

The phenols of lignite tar. J. Frejka and V. Hauk. Masaryk Univ. *Časopis Československého Lékárnictva* **7,** 281–98(1927).—Expts. were conducted on methods for sepn. and isolation of phenols, bases and neutral compds. from lignite tar. The frequently cited method of purification by passing a current of steam through the soln. is unsuitable because of the volatility of some phenols under these conditions. Washing with H_2SO_4 does not give complete sepn. because it dissolves some phenols in addn. to the bases. Detailed results are given on the washing of tar with NaOH solns. of varying concns. William J. Husa

Tests of mechanical and electrical precipitation of tar. F. Seidenschnur and E. Groth. *Brennstoff-Chem.* **9,** 188–93(1928).—Parallel tests are made in which the output of a Koller rotary grate by-product gas producer is detarred in one case by Thyssen centrifugal washer and in another by a Cottrell elec. precipitator. With the washer connected, 13,416 kg. brown-coal briquets were gasified in 68 hrs.; with the precipitator, 11,301 kg. in 61 hrs., an effort being made to secure strictly uniform generator operation in both cases. The washer recovered 95.3% of the tar, the precipitator 99.4%, all tars being practically dust-free, of low water content and otherwise of excellent quality. J. D. Davis

The explosions occurring in the transferring of tar, tar oils, and pitch by compressed air, their supposed causes and their prevention. Leymann. *Zentr. Gewerbehyg. Unfallverhüt.* **14,** 316–25; *Chem. Zentr.* **1927,** II, 2467.—L. compiles the cases known to him, and discusses the causes of the ignition. G. Schwoch

Notes on the (burning) properties of coke. H. Gregor. *Brennstoff-Chem.* **9,** 156–9(1928).—G. dets. ignition and burning properties of coke by kindling a sized coke sample of fixed volume supported on sand in an iron tube, a standard amt. of elec. energy through a wire resistor being used for the kindling. Provision is made for con-

trolled variation of air supply and the results are given as curves showing the relation of air supply rate to rate of consumption of coke. In every case a sharp bend in the curve marks the point of ignition of the coke. J. D. DAVIS

Mechanical strength of coke. G. DÖRFLINGER. *Stahl u. Eisen* **47**, 1867–71 (1927).—The strength is detd. by placing 50 kg. of the coke in pieces of about 50 mm. in diameter in a rotating cylinder which is rotated through 100 revolutions in 4 min. The coke is then screened on a series of screens with holes from 40 mm. to 10 mm. At least 72% should remain on the 40-mm. screen and only a very small quantity of material finer than 10 mm. should be obtained. B. C. A.

Moisture in coke. H. MACPHERSON, L. SLATER AND F. S. SINNATT. *Fuel in Science & Practice* **7**, 444–8(1928).—Moisture-absorption detns. are made upon cokes prepd. in the lab. from 4 coking coals by using, (*a*) the Lessing furnace, (*b*) the Gray-King app. Coal passing a 60-mesh sieve was used and the carbonization temps. ranged from 300° to 900° in 100° stages. Cokes thus prepd. were pulverized, dried, weighed and exposed to the atm. for periods of 24, 48 and 96 hrs. The normal moisture content of the cokes was attained in 24 hrs. A sample carbonized at 700° absorbed the greatest amts. of moisture. D. A. REYNOLDS

Manufacture of coke at Massillon. C. R. LOHREY. Central Alloys Steel Corp. *Blast Furnace & Steel Plant* **16**, 1063–9, 1075(1928).—A detailed description of the layout, construction and operation of a modern by-product coke plant. The process is given in detail from the receipt of the coal to the finished coke and by-products. The results of an av. month's operation are tabulated. J. W. BOECK

Heat balance of the Otto coke-oven battery at the gasworks at Keilehaven, Rotterdam. J. G. DE VOOGD. *Het Gas* **48**, 367–72(1928).—A short heat balance is given of the Otto type coke-oven battery, 50 ovens of 8 tons, 24-hr. coking time, heated by producer gas. On a basis of 15° outside temp., gas or air at standard conditions (0°, 760 mm., dry) the following results were obtained for a coal mixt. of Emma and Maurits (Dutch) pulverized "fat" coal. Per day was carbonized 411800 kg. coal (wet) of 11.50% moisture, 19.98% volatile, 62.20% ash-free coke, 6.32% ash; in the producer plant was used 42962 kg. coke per day (10.4% underfire) of 0.76% moisture, 11.16% ash, 84.85% carbon, 0.57% H_2, 2.66% O + N + S, low calorific value 6911 Cal. (moist); *i. e.*, 720 Cal. in coke per kg. coal carbonized. The carbon loss in ashes was 1.69% of the coke fired (450 kg. per day), the loss in flue dust was 450 kg. per day. Of the producer gas of 1114 Cal. per cu. m. (7.8% CO_2, 23.9% CO, 13.8% H_2, 54.5% N_2, d. 0.880) 202000 cu. m. was consumed per day, representing 540 Cal. per kg. wet coal, the sensible heat of the producer gas (20.4°) being 1 Cal. per kg. coal, sensible heat of air 2 Cal. per kg. coal. The coke yield was 80% of the dry coal at a temp. of 950°, 11.1% ash, sensible heat in coke pushed 232 Cal. per kg. coal carbonized, of which 83.4% was recovered by the dry-quenching installation (128000 kg. steam of 13 atm., 300°, per day). The gas yield was 116167 cu. m. per day at 467° (standpipe) (1.10% CO_2, 1.25% illuminants, 0.85% O_2, 4.05% CO, 20.75% CH_4, 54.70% H_2, 17.30% N_2, 4353 Cal. per cu. m., upper value), tar yield 22 kg. per ton coal with 209 Cal. sensible heat per kg. at 467°, water formed 3% of dry coal weight with 796 Cal., per per kg., a total of 67 Cal. per kg. coal sensible heat in the gaseous products. For the sensible heat of the moisture in the coal 92 Cal. per kg. coal is calcd. at 467°, the sensible heat of the stack gases was for 368000 cu. m. per day at 265°, 16.64% CO_2, 1.90% O_2, 0.06% CO, 81.40% N_2, 84 Cal. per kg. coal, the radiation losses were 101 Cal. per day and per kg. coal. The efficiency of the producer plant was 75% (only 72% of the max. load was used); for the battery the sum total on the left side of the balance lacks 33 Cal. because of exothermic reactions and including all the errors. For dry coal the underfire would have been 458 Cal. per kg. B. J. C. VAN DER HOEVEN

Plant for the heat treatment of fuel and recovery of volatile constituents. OTTO HELLMANN. Fr. 636,043, June 16, 1927.

Distilling powdered fuel. TROCKNUNGS-, VERSCHWELUNGS- UND VERGASUNGS- GES. Brit. 285,015, Feb. 8, 1927. Powd. bituminous material such as coal is injected upwardly into an externally heated distg. chamber and coke formed and distillates are withdrawn from the top of the chamber. Details of the app. used are described.

Liquid fuel mixture. ELMER H. RECORDS. U. S. 1,684,685, Sept. 18. A fuel mixt. suitable for use in internal-combustion engines comprises alc. 72, C_6H_6 18, ether 5, naphthol 2.5, H_2O_2 1.5 and NaOH 1%. U. S. 1,684,686 specifies alc. and water 72, C_6H_6 18, ethyl ether 5, $C_{10}H_8$ 2.5, O (which may be supplied by ozone or H_2O_2) 1.5 and NaOH 1%.

Motor fuel. LOUIS J. P. GUIAUD. Fr. 32,756, Dec. 18, 1926. Addn. to 617,225. Two l. of a mixt. of 70 parts of toluene, 8 parts of naphthalene and 22 parts of mineral oil are added to 5 l. of petroleum spirit.

Pressure-controlled apparatus for proportioning liquid fuel and air supplied to furnaces. BARTON H. NOLAND. U. S. 1,685,031, Sept. 18.

Systems and vaporizing devices for preparing gasified fuel mixtures from atomized liquid fuel and air. ERNEST R. GOODWARD (to Eclipse Petrol Economizer Co., Ltd.). U. S. 1,686,609–10–11, Oct. 9.

Drying powdered coal. N. TESTRUP, O. SODERLUND, T. GRAM and TECHNO-CHEMICAL LABORATORIES, LTD. Brit. 284,405, Oct. 28, 1926. A friable mixt. is formed of coal slurry and dry powder and is dried in a current of air by which it is entrained.

Feeding powdered coal to furnaces. EUGEN WEYHENMEYER. Fr. 635,687, June 9, 1927.

Agglomerates of coal. HOWARD H. DEACON. Fr. 635,217, May 30, 1927. To lessen the amount of agglomerate used, the coal is first mixed with a liquid such as a mineral, animal or vegetable oil or creosote or tar.

Extracting coal and other bituminous materials. P. DVORKOVITZ. Brit. 285,564, Nov. 17, 1926. Bituminous material such as coal, after heating (suitably to about 500°) to distil off part of the org. matter, is treated with a solvent such as petroleum oil or gas tar to ext. addnl. org. matter.

Briquetting coal. HERBERT É. WETHERBEE, RICHARD F. GRANT and HOWARD M. HANNA. Fr. 635,290, May 10, 1927.

Apparatus for gravity separation of coal and ore constituents by use of a liquid and solid mixture of intermediate density. THOMAS M. CHANCE. U. S. 1,686,435, Oct. 2.

Apparatus for producing colloidal fuel by pulverizing coal or similar material in successive stages and treating with oil. HENRY ADAMS. U. S. 1,685,115, Sept. 25.

Carbonization of vegetable materials. SOCIÉTÉ D'ÉTUDES POUR LES COLONIES ET L'ÉTRANGER and MAURICE JUHEL. Fr. 635,682, June 8, 1927. An app. is described for the production of vegetable C, and the recovery of by-products. The chambers are U-shaped.

Water-soluble products from lignite, etc. I. G. FARBENIND. A.-G. Brit. 284,670, Feb. 3, 1927. Lignite and similar fossil materials, which may be degraded by use of sulfite or otherwise, are treated with Cl in the presence of alkali, care being taken to avoid development of acidity during the reaction. Light-colored sol. products contg. Cl are obtained and by gradually adding NaOH during the reaction and thus increasing the salt content a ppt. is formed which may be dried to a yellow powder and ppts. gelatin.

Apparatus for drying peat. M. S. TUIPERMAS. Russ. 3990, Nov. 30, 1927.

Dehydration of peat. SUPREME ECONOMIC COUNSEL OF THE U. S. S. R. Russ. 3851, Oct. 31, 1927. The peat mass is mixed with a colloidal soln. of Fe_2O_3 to coagulate the colloids present and the product obtained is treated as usual, *i. e.*, settled out, filtered and pressed.

Dewatering peat. FELIX GINSBACH (to Heinrich Horst). U. S. 1,686,807, Oct. 9. In dewatering by compression in stages, the first stage comprises compressing and dewatering raw peat after admixt. with peat previously dewatered by compression, and the second stage consists in compressing and dewatering the product of the first stage after adding dry peat.

Manufacture of light oils from complex organic compounds. DANIEL FLORENTIN, ANDRE KLING and CAMILLE MATIGNON. Fr. 32,521, Oct. 23, 1926. Addn. to 608,560. Phenolic oils (phenol, cresol, etc.) yield benzene, etc., when treated with H in the presence of dehydrating catalysts such as alumina or thoria. Tars from low-temp. distn. of oil can also be used if treated with substitution as well as dehydrating catalysts at the same time, *e. g.*, Al_2O_3 and anhydrous $AlCl_3$.

Apparatus for purifying oil of internal-combustion engines by distillation of light substances. JAMES F. WELLS. U. S. 1,686,304, Oct. 2.

Obtaining highly concentrated ammonia gas directly from crude ammonia water. L. F. FOKIN and E. E. LIDER. Russ. 3856, Oct. 31, 1927. NH_3, water vapor and volatile admixtures which are generated by heating crude NH_3 water in a column app. after passing the dephlegmator are cooled below the dissocn. temp. of $(NH_4)_2CO_3$ and $(NH_4)_2S$ to sep. CO_2 and H_2S as solid $(NH_4)_2CO_3$ and $(NH_4)_2S$. These ppts. are removed periodically. The app. for condensing the impurities has an equipment for chilling and heating.

Purification of acetylene. C. H. BOEHRINGER SOHN. Fr. 32,598, Dec. 3, 1926. Addn. to 564,441. C_2H_2 is purified by treating with absorbent material such as active C or active SiO_2 gel. A pretreatment with the usual purifying agents may be made.

Gasifying bituminous fuels. ALBERT BREISIG. Austrian 109,169, Nov. 15, 1927. In complete gasification of bituminous fuels the hot gases from the blasting period are used to heat accumulators which serve to superheat the steam during the "run" and also the whole or part of the gases produced. These gases are led back into the producer. The improvement consists in operating the process so as to obtain a surplus of coke, which is continuously removed.

Heating or gasifying apparatus. GEZA SZIKLA. Austrian 109,020, June 15, 1926. The app. is of the kind in which finely divided solid or liquid fuel is fed in near the bottom of a shaft and burned or heated by an ascending current of gas.

Furnace construction in which a primary combustion chamber serves as a gas producer with powdered or liquid fuel. E. S. SUFFERN, GASIFIED FUEL, LTD., H. E. HAZELHURST and O. MARGETSON. Brit. 284,738, Sept. 1, 1926.

Tube and header heat exchange apparatus for treating coal gas, water gas or other gases. H. TINDALE. Brit. 284,413, Nov. 1, 1926.

Gas-producer construction and operation. SOC. DE CONSTRUCTION D'APPAREILS POUR GAZ A L'EAU ET GAS INDUSTRIELS (to Humphreys & Glasgow, Ltd.). Brit. 285,004, Feb. 8, 1927. Steam and O are supplied to a gas producer so that heat generated by the O maintains the fuel bed sufficiently hot for the continued generation of water gas by the steam, after a preliminary blasting with air or O. Various details of construction are described.

Gas producers for feeding motors. ÉLIE JAQUES. Fr. 635,254, May 31, 1927. Two furnaces are provided which are used alternately, the gaseous products from the lighted furnace being obliged to pass through the unlighted one.

Fuel gas. FRITZ WINKLER (to I. G. Farbenind. A.-G.). U. S. 1,687,118, Oct. 9. In mfg. fuel gas in a generator having a bed of small-sized, incandescent carbonaceous material supported by a grate, gas such as air and steam is blown through the material with sufficient speed to cause a "boiling action" in the material and to effect gasification reaction. An app. is described.

Coal-gas and oxygen burner. WM. S. BARKER. U. S. 1,686,508, Oct. 9. Structural details.

Gas purifier. ÉLIE JAQUES. Fr. 635,255, May 31, 1927. Constructional features.

Gas purification. FREDERICK W. SPERR, JR. (to The Koppers Co.). Can. 283,774, Oct. 2, 1928. H_2S is absorbed by means of a wash liquor contg. an Fe compd.; NH_3 is recovered by distn. of the wash liquor; and the distn. residue is aerated to regenerate the Fe compd. with liberation of S.

Gas-purification apparatus. FREDERICK W. SPERR, JR. (to The Koppers Co.). Can. 283,776, Oct. 2, 1928. App. for carrying out the process of the preceding patent is specified.

Scrubber device for washing gases in furnace flues. W. W. ROBINSON. Brit. 284,919, June 7, 1927.

Apparatus for utilizing impure or exhaust gases containing carbon dioxide. FRIEDRICH RIEDEL (to Riedel Fertilizing Process Co.). U. S. 1,687,229, Oct. 9. Combustion gases from carbonaceous fuel are introduced into an alk. soln. such as Na_2CO_3 or K_2CO_3 which may be contained in a vessel heated by fuel from which the combustion gases are produced, and gases after passing through the soln. are led under gentle expansive force into proximity to growing plants.

Treating tar. F. C. BUNGE and H. MACURA. Brit. 285,000, Feb. 8, 1927. See Fr. 633,643 (*C. A.* **22**, 3519).

Distilling tar. S. P. MILLER (to Barrett Co.). Brit. 284,703, Feb. 5, 1927. Hot gases from coke ovens are used for the distn. of tar by spraying the tar into the hot gases in a collecting main to which the gases are led from a plurality of ovens. The vapors thus formed are removed from the distn. main and are cooled and condensed. Various details of the app. used are described. Cf. *C. A.* **22**, 3764.

Distillation of coal tar. CARL WESSEL. Fr. 636,053, June 16, 1927. See Brit. 273,675 (*C. A.* **22**, 2049).

Dehydrating and distilling tars and oils. DOUGLAS RIDER (to Thermal Industrial and Chemical Research Co., Ltd.). U. S. 1,685,034, Sept. 18. The liquid to be treated is passed through a duct immersed in a bath of molten metal, which is maintained at a temp. but a few degrees higher than the b. p. of the fraction that it is desired to vaporize, and the liquid is caused to issue from the duct above the surface of the molten metal and to spread over the latter in an even layer. An app. is described.

Breaking aqueous emulsions of tar. B. JOHNSON. Brit. 284,401, Oct. 27, 1926. Aq. emulsions of tar are broken by adding a carboxylic acid which is sol. in the tar but not in the water; *e. g.*, resin acids, oleic acid, stearic acid, palmitic acid, arachidic acid or linolenic acid may be used. Alkali in sufficient quantity to make the sepd. water alk. may be preliminarily added to tar emulsions not contg. NH_3.

Resolving emulsions of tar or oil. HERBERT W. ROBINSON and DERIC W. PARKES. U. S. 1,687,314, Oct. 9. See Brit. 268,547 (*C. A.* **22**, 1419).

Coke. CHARLES L. WAGGONER and FRANK B. THACHER (to By-Products Coke Corp.). U. S. 1,685,654, Sept. 25. In order to improve the properties and lessen clinkering of coke produced by high-temp. distn. processes and brought to a porous condition of relatively low d. with the oily substances and volatile constituents substantially completely removed, the porous mass, subsequent to the high-temp. distn., is treated with a moisture-absorbing substance of the Ba group, *e. g.*, $CaCl_2$.

Means for discharging coke from gas generators. ALBERT BREISIG. Austrian 108,912, Oct. 15, 1927. Constructional details.

Machine for evacuating coke furnaces. NAAMLOOZE VENNOOTSCHAP, SILICA EN OVENBOUW MAATSCHAPPIJ. Fr. 636,051, June 16, 1927.

Device for cleaning carbon deposits from inside of coke ovens by use of blasts of compressed air, etc. J. A. LOVETT (to Koppers Co.). Brit. 285,070, Feb. 12, 1927.

Quenching coke. SOC. GÉNÉRALE DE FOURS À COKE SYSTEME LECOCQ. Brit. 284,721, Feb. 5, 1927. Steam produced in quenching hot coke is treated, before escaping to the atm., with a water spray to free it from coke dust and to effect partial condensation. An app. is described.

Vertically flued coke-oven construction. C. WESSEL. Brit. 284,606, Jan. 31, 1927.

Coke-oven construction and discharging apparatus. C. B. COLLINS and J. A. B. LOVETT (to Koppers Co.). Brit. 284,311, Jan. 29, 1927.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Dephlegmation. K. V. Kostrin and N. M. Akopov. *Neftyanoe Khozyaistvo* **13,** 311–6(1927).—A lab distg. flask is connected to a vertical glass tube 30 mm. wide and 300 mm. high insulated with 50 mm. of asbestos. A glass U-tube connects this tower with the top of a reflux condenser. The bottom outlet of this reflux condenser has a glass T, one side of which is connected to a Liebig condenser and the other to a gas trap, which can be connected either to a second Liebig condenser or directly with the still. The jacket of the reflux condenser is used for steam to hold the vapors at a const. temp. The distn. can be run either on the open fire or on steam. The vapors are carried through the 300-mm. insulated glass tube through the top of the reflux condenser, which acts as a dephlegmator. Part of the vapors are condensed and passing the gas trap enter the Liebig condenser or the still. The uncondensed vapors are condensed in the 2nd condenser. The table below shows the work performed by this app.: (I) with open fire without redistn. of the condensate from the reflux condenser, (II) same with steam but no fire, (III) open fire and redistn. of the condensate, (IV) steam but no fire.

	I	II	III	IV
Charge	3000g.	3000g.	3000g.	3000g.
Highest temp. of vapors	97°	98°	97°	98°
Distillate obtained	49g. (1 63%)	1965g. (65.50%)	181g. (6.03%)	1967g. (65.57%)
Reflux	187g.	165g.	....	....
Sp. gr. of distillate	0.7282	0 7820	0.7472	0.7790
Sp. gr. of reflux	0.7611	0.8050	....	....
H_2O condensate with distillate	....	1860g.	....	1854g.
H_2O condensate with reflux	....	700g.	....	....
Temp. of steam	....	170°	....	170°
I.b.p.	63°	46°	64°	48°
Engler distillation:				
I.b.p. of distillate	46°	88°	68°	88°
I.b.p. of reflux	78	115	....	....
25% off distillate	75	121	83	118
25% off reflux	94	157	....	....
50% off distillate	83	137	88	133
50% off reflux	101	173	....	....
95% off distillate	110	191	117	192
95% off reflux	149	225	....	....

Temp. in the dephlegmator (reflux condenser) when the still was heated with fire was 173°, with steam only 98°. Red Surakhanui crude oil was used for this expt. This expt. confirms the results obtained by N. A. Alekseyev (*Azerbeydj. Neft. Khoz.* **1926,** No. 2, 65; **1927,** No. 3, 49–53. A. A. Boehtlingk

The petroleum industry in the year 1927. Richard Kissling. *Erdöl u. Teer* **4,** 440–2, 458–9, 475–8(1928).—A review with references. F. S. Granger

World production of petroleum in 1927. J. Filhol. *Ann. office nat. comb. liquides* **3,** 283–307(1928).—A statistical review which compares the production for 1927 with the yearly production for the period 1910–27. R. E. Schaad

Petroleum and petroleum products. Arthur Knapp. *Mineral Ind.* **36,** 415–45 (1927).—World production, refining and advances in technology are discussed; also oil shales and natural gas. A. B.

Things one should know about petroleum and its products. A. A. Potter and H. L. Solberg. Purdue Univ. *Power* **68,** 523–6(1928).—A general discussion. D. B. Dill

Insulating pipes and tanks in an oil refinery. H. L. Kauffman. *Power* **68,** 511–2 (1928).—Details are given for insulating refrigerating equipment. D. B. Dill

The oil field salt water pollution problem. J. G. McIntosh. *Proc. 10th Texas Water Works Short School* **1928,** 247–50; *U. S. Pub. Health Eng. Abstracts* **E-637,** 50 (1928). J. A. Kennedy

Metallic alloys in the mineral-oil industry. Hans Magnus. *Metallbörse* **17,** 1463; *Chem. Zentr.* **1927,** II, 1112. J. S. Reichert

Composition of petroleum and its products. GEORGE A. BURRELL. *Fuel in Science & Practice* **7**, 416–23, 463–5(1928).—See *C. A.* **22**, 2832. D. A. REYNOLDS

First attempts at an independent solution of the naphtha question in Poland. W. DIAMAND. *Przemysl Chem.* **12**, 255–61(1928). Largely statistical. *Ibid* **12**, 299–307.—Discusses the economics of difficulties of the Polish petroleum situation. A. C. Z.

The chemical composition of bituminous slates and the crude oils to be manufactured from these, with special regard to the sulfur-rich ichthyol oils as a technological index of their value. RUDOLPH NIEDERLEUTHNER. *Wiss. Mitt. Österreichischen Heilmittelstelle* 1927, 6–8; *Chem. Zentr.* 1927, II, 1318. G. SCHWOCH

Oil recovery through the use of natural gas. E. O. BENNETT. *Oil Bull.* **14**, 826–8(1928).—Gas dissolved in oil lowers the viscosity of the oil and so facilitates its flow through the oil sands. It is almost impossible, however, to replace gas in soln. in the oil remaining in a subsurface structure since agitation cannot be effected. It is therefore desirable to limit the amt. of gas produced from an oil well as nearly as possible to that originally in the oil reservoir that was drilled into. Observed data indicate that repressuring started during the first 5% of the normal life of the field will result in an ultimate production of 200–300% more than where the gas is not conserved. D. F. BROWN

Combating paraffin and associated production problems in Texas panhandle. L. L. BECHTEL AND W. O. BLENKARN. Am. Petroleum Inst. Development & Production Eng., *Bull.* No. **202**, 133–7(1928).—Paraffin deposits in pumping wells are best removed by steaming or with elec. heaters. Hot water may also be used. Wells normally producing a high percentage of water are usually fairly free from paraffin trouble. In gas lift wells a scraper is usually used. The use of steam heating on gas lift wells where S gas is found is not recommended because of the accelerated corrosion due to the moisture. Paraffin deposits in or on the walls of the bottom hole formation are best removed by washing with hot water or lye soln. D. F. BROWN

The influence of colloids and suspensoids on the solubility of gases in liquids. FRANK E. GERMANN. Am. Petroleum Inst. Development & Production Eng., *Bull.* No. **202**, 101–5(1928); cf. *C. A.* **22**, 3769.—Adsorption of gas upon solid surfaces probably accounts for the apparent greater soly. of gas in oil contg. sand than in pure oil. Factors effecting the soly. of gas in liquid contg. suspended solids are whether adsorption of the gas on the solid surface is pos. or negative, the order of magnitude of the adsorption, size of the solid particles, compactness of the solid particles, vapor tension and vapor pressure of the liquid, temp. and curvature of the surface. Until it is known definitely what laws are operative, underground conditions cannot be explained or forecast by means of laws which are known to apply to solns. free of all solid matter. D. F. BROWN

Scientific foundations of the refining of petroleum. V. Cracking. A. E. DUNSTAN. *J. Roy. Soc. Arts* **76**, 1001–24(1928); cf. *C. A.* **22**, 4235.—A lecture (the last of the series) covering a brief description of the main cracking processes, berginization, the refining of cracked distillates, and the production of alc. and their derivs. from the unsatd. gases from cracking stills. G. CALINGAERT

The manufacture of gasoline by cracking oils. F. KOUDELÁK. *Paliva a Topení* **10**, 36–7, 51–6(1928).—A review of about 10 com. processes in current use. F. M.

Fifteen years of the Burton process. R. E. WILSON. *Ind. Eng. Chem.* **20**, 1099–1101(1928).—A short outline of the history of the Burton cracking process and of its influence on the development of the oil industry. G. CALINGAERT

Use of the float and sink method for isolation of organic matter in oil shales. K. LUTS. *Brennstoff-Chem.* **9**, 217–8(1928).—Treatment of the shales with 5% HNO_3 and H_2F_2 gives more complete removal of mineral matter (to 1% total) than the recommended treatment with HCl and H_2F_2. In both methods, however, org. matter is attacked as evidenced by its change of color. L. treats the finely powd. shale with $CaCl_2$ soln. of 1.06 to 1.15 sp. gr. and whirls on a centrifuge at 3000 r. p. m. till all the organic matter rises to the top of the container. This is easily filtered and washed free from $CaCl_2$. Ash is reduced to a total of 3 to 7%. J. D. DAVIS

Methods of estimating paraffin hydrocarbons in commercial benzene and motor fuel. R. HEILINGÖTTER. *Chem.-Ztg.* **52**, 437–8(1928).—A critical review. The Me_2SO_4 absorption method is unreliable for detg. paraffin hydrocarbons (cf. Graefe, *C. A.* **1**, 1909). Benzine-C_6H_6 mixts. contg. less than 50% of benzine cannot be sepd. by the method of Kattwinkel (*C. A.* **19**, 1113), in which Ac_2O contg. AcSH is used. The refractometer method proposed by Pritzker and Jungkunz (*C. A.* **17**, 2188) also gives inaccurate results (cf. Wolff, *C. A.* **17**, 2779). The most reliable method of

detg. benzine in fuels depends upon its insoly. in fuming H_2SO_4 which sulfonates and dissolves aromatic hydrocarbons. R. E. SCHAAD

Action of accelerators and inhibitors upon the oxidation of liquid hydrocarbons. T. E. LAYNG AND M. A. YOUKER. *Ind. Eng. Chem.* **20**, 1048–52(1928).—Motor fuels such as heptane, gasoline and kerosene were oxidized by heating with O in a glass bulb and the effect of various antiknock substances on the rate of oxidation was observed. Oxidation of heptane in the gas phase appears not to be through its normal alc. Heptyl alc. may be oxidized only with difficulty in the gas phase. Lead tetraethyl delays the accelerating action of butyl nitrite, but if once started the path of oxidation is the same as when not delayed. Aniline, diphenylamine, lead tetraethyl and K ethylate are all inhibitors of gas-phase oxidation. There is no relation between the engine test evaluation of inhibitors and the values obtained in their slow oxidation data for gas-phase oxidation. EtOH, aniline, diphenylamine and Al ethylate are not accelerators of liquid-phase oxidation. Lead tetraethyl and K and Na ethylate are accelerators of liquid-phase oxidation when present in extremely small percentages. Lead tetraethyl and K and Na ethylate exhibit a surprising similarity in their effect on gas and liquid-phase oxidation. The data obtained are not thought to affect the peroxide theory of hydrocarbon oxidation. The data indicate that an ideal antiknock substance might be obtained by incorporating a powerful inhibitor of only vapor-phase oxidation with a powerful accelerator of only liquid-phase oxidation.
D. F. BROWN

Determination of unsaturated hydrocarbons in gasoline by means of bromine. G. ZD'ÁRSKÝ. *Chem. obzor* **3**, 165–8, 205–10(1928).—The absorption of Br by gasoline depends (1) on the time of action of Br on the gasoline, (2) on the ratio of gasoline to Br and (3) on the method of shaking. Br sepd. from 0.1 *N* KBr and $KBrO_3$ soln. by means of H_2SO_4 (20%) does not react readily with Kahlbaum's normal gasoline in the absence of light but a remarkable absorption takes place on using 0.1 *N* Br water. The soln. turns acid, the acidity being approx. directly proportional (till about half of the Br soln. is used up) to the quantity of Br consumed. The action of Br on gasoline hydrocarbons is, therefore, not a simple addn. of Br by unsatd. hydrocarbons. The formation of HBr indicates also that the formation of HBrO and brominated hydrocarbons or that other complicated reactions are taking place. An app. is described for assuring the exact measurement of Br water and a small bottle with a funnel is devised for eliminating the loss of Br during the expts. JAROSLAV KUČERA

Flame characteristics of "pinking" and "non-pinking" fuels. G. B. MAXWELL AND R. V. WHEELER. Sheffield Univ., Eng. *Fuel in Science & Practice* **7**, 383–97. —See *C. A.* **22**, 3038. D. A. REYNOLDS

Hydrogenation in the petroleum industry. H. I. WATERMAN AND J. N. J. PERQUIN. *J. Inst. Petroleum Tech.* **11**, 36–60(1925).—In the introduction the authors discuss the *hydrogenation of cottonseed oil* at very high pressures and the transformation of the oil at high temps. At 450° a high percentage of hydrocarbons is formed and from the O balances it is shown that the larger part of the O is expelled after a very short time. Further the Bergius process is discussed and some details are given about expts. carried out at high temps. with paraffin wax under high pressures caused by different gases such as CH_4, N_2 and H_2 and with nascent H produced by the reaction $CO + H_2O \longrightarrow CO_2 + 2H$. Only H under high pressure gives the most favorable results. The second part of the paper deals with the decompn. of paraffin wax in the presence and absence of H under high pressure. This part has already been abstracted (*C. A.* **19**, 1345) from an incomplete copy of the original paper. H. I. W.

Some flame characteristics of motor fuels. G. B. MAXWELL AND R. V. WHEELER. Sheffield Univ., England. *Ind. Eng. Chem.* **20**, 1041–4(1928); cf. *C. A.* **22**, 3038.—From a study of flame movement and pressure development in a cylinder during the combustion of pentane-air, benzene-air, pentane-benzene-air, pentane-ethyl ether-air mixts. it is concluded that "pinking" explosions are due to the completion of combustion behind the flame front from the impetus of a shock wave when the vibrating flame is arrested. The decompn. products of lead tetraethyl are responsible for its antiknock quality. ARTHUR FLEISCHER

Importance of mixture ratio in rating fuels for knock. JOHN M. CAMPBELL, WHEELER G. LOVELL AND T. A. BOYD. Research Lab. General Motors Corp., Detroit, Mich. *Ind. Eng. Chem.* **20**, 1045–8(1928).—The max. knock-fuel ratio curves detd. for benzene-gasoline blends contg. varying quantities of lead tetraethyl and for heptane-isooctane mixts. show a max. knock at a given fuel-air ratio. Mixt. ratios giving max. knock are advocated as a means of getting consistent results between different labs. ARTHUR FLEISCHER

Self ignition and detonation. ARNOŠT VYSOKÝ. *Paliva a Topení* **10,** 9–14(1928).—A discussion of fundamental principles involved in detonation of fuels in high-compression engines. FRANK MARSH

Evaluation of gas oils. Chemical considerations and analytical methods. T. A. MIGHILL. Pawtucket Gas Co., Pawtucket, R. I. *Proc. Am. Gas Assocn.* **1927,** 1454–63.—The following premises are used as an argument for the possibility of evaluating a gas oil: (1) Since all gas oils boil over about the same range, it is likely that there will be about the same individual members in each series; (2) each hydrocarbon will have its characteristic efficiency of pyrogenic decompn. at any fixed temp., where the efficiency means the amt. of heat of combustion added permanently to the gas from the thermal decompn. of a gallon of gas oil divided by the heat of combustion of a gallon of the same oil; (3) the analysis of a gas oil gives roughly the % of each series; (4) by assigning a heat efficiency to each series and detg. the % of the series in the oil, the product of these percentages should give the efficiency of the series in that oil; (5) the total heat efficiency of the oil will be the sum of the partial efficiencies as detd. by (4). By cracking the oil in a hot tube and detg. the B. t. u. added to the gas from a known amt. of oil, combined with an analysis of the oil, the following provisional efficiencies for each of the four series of hydrocarbons have been obtained: paraffins 100% (arbitrary); naphthenes 70%; aromatics 50%; and unsaturates 25%. The following analytical methods are proposed: *Unsaturates.*—Place 15 cc. of the oil and 30 cc. concd. H_2SO_4 in a straight long-necked flask; cool the mixt. for $^1/_2$ hr. in ice-H_2O. Turn the contents of the flask into a centrifugal tube and rinse the flask with H_2SO_4 into the same tube. Centrifuge and read the vol. of unattacked oil. From the loss divided by the original 15 cc., det. the % of unsaturates. *Aromatics.*—Pipet 10 cc. of the residue from the above treatment into a small separatory funnel. Put 15 cc. fuming HNO_3 in a centrifugal tube cooled in a freezing mixt. of ice and salt. Pour the oil (a few drops at a time) into the HNO_3, stirring the mixt. ($^3/_4$ hr. required to add all the oil). Allow the mixt. to stand 15 min. and then centrifuge. Of the 3 layers appearing, read the top layer and subtract from 10, which gives the cc. of aromatics used. *Naphthenes.*—Place 5 cc. of the oil unattacked by the above treatment in a long-necked, straight flask, and add 10 cc. (1:1 by wt.) of a mixt. of H_2SO_4 and HNO_3. Float the flask on H_2O which is simmering, shaking the flask often. When oxides of N cease to be evolved (after about 2 hrs.), transfer the still warm contents of the flask into a centrifuge tube, rinsing out the flask with 3 portions of acid into the tube. The oxidized products can be sepd. from the remaining oil with petroleum ether as follows: Add 8 cc. petroleum ether to the tube and stir with an air current, centrifuge and read the amt. of waxy matter. Cool the tube in ice water and reread. Add 8 cc. of the ether and repeat the procedure. If the reading shows a diminution of more than a few tenths of a cc., repeat the procedure with 8 cc. petroleum ether. *Paraffins.*—These are obtained by difference, 100 − % of [unsaturates + aromatics + naphthenes]. J. H. PERRY

Uniformity in Diesel fuel oil specifications. G. H. MICHLER. Standard Oil Co., N. J. *Power* **68,** 191–4(1928).—See *C. A.* **22,** 3768. D. B. DILL

Navy specifications for Diesel oil. H. C. DINGER. *Power* **68,** 556–7(1928).—The principal requirements are: min. flash point 150° F.; max. viscosity, 200 sec. at 32° F.; max. water and sediment, 0.5%; max. S, 1.5%; max. ash, 0.1%. D. B. DILL

Burning boiler oil in Diesel engines. JAMES M. BLOOMFIELD. *Power* **68,** 594–5 (1928).—After some experimentation, successful use was made of boiler oil of the following properties: gr., 12.25° Bé., *flash point,* 290° F.; *viscosity* at 122° F., 27 sec. Saybolt. D. B. DILL

Principles of steel mill lubrication. E. P. MALLISON. *Iron Age* **122,** 827–31 (1928). E. J. C.

Changes in transformer oils. II. K. TYPKE. *Z. angew. Chem.* **41,** 418–25 (1928).—A review of recent literature dealing with the nature of the changes which take place in transformer oils during use, the products formed, and precautions to be taken to retard the progress of these changes. B. C. A.

The aging of transformer oils. I. K. TYPKE. A. E. G., Berlin. *Z. angew. Chem.* **41,** 148–53(1928).—This first part of T.'s review discusses the following factors of the aging of transformer oils: O, refining of the oil, temp., time, substances coming in contact with the oil, admixt. of other oils, light, elec. field. 74 references. G. C.

Insulating oils for high-voltage cables. T. N. RILEY AND T. R. SCOTT. *J. (Brit.) Inst. Elec. Eng.* **66,** 805–40(1928); cf. *C. A.* **22,** 1637.—The general requirements of oils for insulating high-voltage cables are described. Flash point is usually between 260° and 315°. The effects of variation in *set point* upon *power factor* are described as well as the influence of various factors upon set point. Viscosity is detd. in abs. units by

the U-tube method. A steep viscosity-temp. curve is desirable if not obtained by addition of resin. The d. c. resistance of oils increases with time, this being apparently due to the building up of contact resistance. In detg. a. c. characteristics, accurate measurement of *leakance* and capacity is necessary. Power factor can be taken as $G/(\omega C)$, where G = leakance, $\omega = 2\pi \times$ frequency and C = capacity. Power factor-temp. characteristics are important in relation to the actual value of dielec. losses, and as an index of the chem. and phys. stability of the oil. The elimination of gas pockets in the dielec. is essential, not only to prevent burning and oil oxidation, but to obtain low thermal resistivity. The variation in power factor with long heating is measured, the increase in power factor affording a measure of deterioration. Curves are shown. H. Stoertz

Methods of testing transformer oils. I. Musatti and R. Volterra. Istituto Scientifico Tecnico Ernesto Breda, Milano. *Giorn. chim. ind. applicata* **10**, 397–408 (1928).—In continuation of work on the oxidation of transformer oils (cf. M. and Pichetto, *C. A.* **19**, 3584), expts. were directed toward developing a method sufficiently rapid and precise to classify oils according to their resistance to deterioration in service. All methods based on oxidation in the open are subject to grave errors, a very large part of the products being eliminated, so that quite different results are obtained from those under conditions where the products are retained. Moreover, these methods are long and troublesome. An attempt was therefore made to develop a rapid *method* of oxidation out of contact of air, either in O in a closed medium or by conducting in O under const. pressure in the absence or in the presence of Cu. The expts., which deal particularly with the factors which influence the oxidation, indicate that the optimum conditions are to heat the oil 2–3 hrs. at 200°, with a const. pressure of O. The accelerating action of Cu, which is almost negligible in a closed medium, becomes intense when operating at a const. pressure of O. The nature of the oxidation process remains, however, essentially the same either in the presence or in the absence of Cu, so that the utilization of Cu to accelerate the deterioration is justified. The curves which express the course of the oxidation as a function of time are similar whether Cu is present or absent, the curves of the sludge diverging from the time axes and the acidity curves bending toward them. The 2 methods of testing which were studied, *viz.*, atm. oxidation in Cu cylinders and oxidation in a medium of O, lead in general to similar classifications of oils with respect to their tendency to form sludge. Oxidation in a medium of O, however, gives results which distinguish the oils better one from another. In the method of oxidation with air the acid content was too low. There was no relation apparent between the 2 methods described and the "life test." The latter and the method of oxidation in O at const. pressure seemed in conjunction with one another to classify oils in the order of their resistance to deterioration, the "life test" giving a measure of the resistance of an oil to form a sludge, and oxidation in O at const. pressure giving a measure of the velocity of this sludge formation and the accompanying formation of acid. C. C. Davis

Fundamental viewpoints in judging the resistance of insulating oils against oxidation. S. Fachini and C. Borella. *Chem. Umschau Fette, Oele, Wachse u. Harze* **34**, 331–4(1927).—All tests have the following procedure in common: the oil is heated to a certain temp. for a given length of time; the reaction products are detd. and they furnish a clue as to the quality of the oil. The following points are discussed: (1) *Temp.*—It varies between 100° and 175°; the most generally accepted temp. is 110°. (2) *Heating.*—The covered thermostat is preferable to an exposed oil surface on account of the variability of air currents. (3) *Vessel.*—Metals act as oxidizing catalysts to a varying degree; glass less so; the same type of vessel must be used to obtain comparable results. (4) *Oil.*—The quantity employed varies between 10 g. (French method) and 1000 cc. (Swiss method). The ratio of oil vol. to exposed surface dets. the speed of reaction; a small surface is recommended to prevent too rapid and uneven oxidation. (5) *Catalyst.*—The presence of an oxidizing catalyst, Cu in gauze or sheet form, is preferred for reproducible results; its total surface is of secondary importance. (6) *Air.*—The passing of air or O_2 through the oil shortens the time but burdens manipulation; it is unnecessary when Cu is present. (7). *Electrostatic field.*—The present information on this point is quite vague. (8) *Time.*—It varies between 5 hrs. and 25 days. Its length is arbitrarily selected; the Italian standard of 300 hrs. yields sufficient oxidation products for accurate detns. (9) *Oxidation products.*—This is the most important consideration. The change in color is no criterion of quality but gives a safe guide as to the origin of the oil; darkened oils result from American (paraffin) oils; light colors from Russian (naphthene) oils. The depth of color is not proportional to the amt. of sediment or to the amt. of acids formed. Total sediment (insol.

in standard benzine) and total acids (the intermediate product) must both be detd.; omission of one of the two furnishes an incomplete picture. The action of the oil upon cotton fiber is only of informative character without abs. value. P. ESCHER

Manufacture of insulating oils. TYPKE. *Allg. Öl u. Fett-Ztg.* **24,** 552–3; *Chem. Zentr.* **1927,** II, 2635; cf. *C. A.* **22,** 159, 863.—Useful insulating oils have been obtained only from petroleum, except for the expensive rosin oils. As to the triaryl phosphates manufd. by the I. G. Farbenind., it must be noted that they are heavier than H_2O, so that H_2O in the oil might rise to the surface and cause a discharge. G. SCHWOCH

Renovation of used lubricating oils. K. HORNSTEIN. *Seifensieder-Ztg.* **53,** 910 (1926).—H. replies to Typke (*C. A.* **22,** 863), showing that in practice the assembling of used lubricating oils and their subsequent purification and distn. present greater difficulties than is anticipated by T. P. ESCHER

Determination of water in oils and tar. ANTONIO VALENTE DO COUTO. *Chimica Industria* **3,** 462(1928).—For oils, contg. about 3–5% water, which cannot be detd. in the usual way by a fractional distn., the following method is recommended: in an Engler flask, connected to a condenser, heat 50 cc. of a high-boiling, water-free mineral oil near its boiling temp. Dil. 50 cc. of the emulsion to be examd. with 50 cc. of a light hydrocarbon (with tar benzene may be used) and add drop by drop. Collect the evapd. and condensed water in a graduated tube, contg. the same solvent as used to dil. the emulsion; the water forms a sep. layer and its vol. is read directly. Moisture not in emulsion, but simply adsorbed, is easily detd. by shaking the oil with H_2SO_4. R. D. BUMBACHER

Heat transfer in oils flowing through pipes. M. GARCIA. Gulf Refining Co., Port Arthur, Tex. *Ind. Eng. Chem.* **20,** 889–91(1928).—Methods commonly used for the calcn. of heat transfer rates are satisfactory for H_2O and gases, but for oils and other highly viscous liquids the variables involved require certain modifications. The sp. heat of gases and liquids is a function of the temp., and the transfer coeffs. depend on the phys. properties of the fluids that vary with the temp. For petroleum these variations are of such order that the assumption of constancy is not justified; therefore a new expression for "mean temp." must be derived. Thus for heat transfer between a liquid in a pipe and the wall, when the wall temp. is const., let dS be an element of surface of the pipe wall, and dt the differential change in temp. of the liquid flowing past the surface, then $wcdt = -(T - t)dS/r$, where w = wt. of liquid flowing per unit time, c = sp. heat, T = pipe wall temp., t = liquid temp., and r = thermal resistance of liquid film. This gives $S = -w\int_{t_1}^{t_2} \frac{rcdt}{T - t}$, representing the law of temp. variation along the pipe. From the work of others G. derives values for r, c and exptl. consts. involved in applying this formula in practical work. Graphical methods are given for the calcn. of mean liquid temps. and mean temp. differences to be used in the correlation of exptl. data or the design of exchangers for heavy viscous oils involving large temp. ranges. The method of calcn. is illustrated by specific instances from every-day work. W. C. EBAUGH

The spreading of lubricants on solid surfaces. PAUL WOOG. *Ann. office nat. comb. liquides* **3,** 271–3(1928).—See *C. A.* **22,** 1231. R. E. SCHAAD

Comparative tests of two mazouts under a steam ship boiler. G. U. KOZLINSKII. *Izvestiya Teplotekh. Inst.* (*Bull. Inst. Fuel Research* (*Russia*)) **1926,** No. 1, 56–83.—The characteristics of the mazouts used are, for Grozny paraffin mazout: sp. gr. 0.896, cold test (Holde) 30°, paraffin wax 9.07%, max. calorific value 10,760 kg./cal., compn.: C 85.80, H 12.81, O and N 0.25, ash 0.0, S 0.21, H_2O 0.93%, min. calorific value 10,065 kg./cal., compn. of the ash and water-free part: C 86.61, H 12.93, O and N 0.25, S 0.21%, min. calorific value 10,166 kg./cal. Corresponding values for the other mazout are: 0.910, uncertain, none, 10,104, 81.10, 11.86, 0.70, 0.04, 0.16, 6.14, 9399, 86.45, 12.64, 0.074, 0.17 and 10,057. The Grozny mazout was warmed by a steam coil before being sent to the oil burner; the other mazout was used at ordinary temp. The atomization of fuel in both cases was carried out with steam, the Grozny mazout consuming more steam, which disadvantage was made good by its higher calorific value. 977,000 cal. were required to keep the Grozny mazout at about 40° for 157 hrs. The upkeep expenses for Grozny mazout were 1% higher than for the other, owing partly to a low outside temp. (1°), whence 1^1/$_2$% more steam was generated. No coke or soot formation was noticed. The Grozny mazout can be used accordingly with the same results as with paraffin-free mazout. A. A. BOEHTLINGK

So-called pitch number of oils. S. GASIOROWSKI AND S. PILAT. Polytech. Lwow. *Przemysl Chem.* **12,** 235–9(1928).—Pitch no. can give no satisfactory indication of the

kind of cylinder oil a given raw material will produce. On heating different oils at 200° for 2 hrs. those oils which originally had a low asphalt content scarcely increased it at all, and those with higher asphalt content, 0.14% and 1.28%, increased it by 70% to 300% regardless of the pitch no. A. C. Z.

The determination of tar number of oils. H. v. d. Heyden and K. Typke. Chem. Lab. A. E. G. Transformatoren-fabrik Berlin-Oberschöneweide. *Chem.-Ztg.* **52,** 150 (1928).—It has been proposed by Marcusson and Bauerschäfer (*C. A.* **20,** 2743) to det. the tar no. of an oil by heating 50 g. oil in the presence of 10 g. pumice soaked in NaOH at 120° for 24 hrs. in a 200-cc. flask, instead of the usual procedure (referee method) consisting of heating 150 parts by wt. of oil in a 300-cc. flask for 70 hrs. at 120° in a current of O_2. By an examn. of 5 types of oil, H. and T. conclude that there is no basis for substituting M. and B.'s method for the referee method. The former method gave much higher results than the latter. J. H. Perry

The determination of asphalt in paraffin oils. J. Mžourek. *Paliva a Topení* **10,** 1–3(1928).—Five g. oil are placed in an Erlenmeyer flask and refluxed with 40 times its vol. of normal benzine for 2–3 hrs. The liquid is cooled 1/2 hr., decanted and filtered. The pptd. asphalts are washed with normal benzine. From here the analysis follows the cold method of Holde. The described method reduces the total analysis to 4 hrs., removes asphalts very completely (the filtrates remain colorless for several days), and yields results comparable to other methods. The grades of benzine used had no effect upon the results. A résumé in French follows. Frank Maresh

Asphalt-precipitating benzine. H. Burstin and J. Winkler. Lab. of Refinery "Galicja," Drohobycz, Poland. *Przemysl Chem.* **12,** 445–63(1928).—The object was to prep. from Polish raw materials benzine suitable for pptg. asphaltines from mineral oils which would conform to the specifications of D. Holde (*Wasserstoffole u. Fette,* p. 135). Gasoline and cracked benzine yielded products superior to Kahlbaum's standard. On this basis, new specifications are drawn up for pptg benzine: d_{15} 0.685–0.695; b. p. limits 65–95°; refinery no. up to 2%. New addns. to the old specifications are recommended: aniline point over 64°; n_{20} under 1.3950; 65–80° fraction must represent no more than 70% benzine; 80–95° fraction must have d_{15} below 0.700, and n_{20} below 1.4000. A. C. Zachlin

Asphalt. Prévost Hubbard. *Mineral Ind.* **36,** 49–55(1927).—A discussion of asphalt varieties, production, imports and exports, etc. A. B.

Determining ceresin in ozocerite and in paraffin tars. V. Tokmanov. *Neftyanoe Khozyaistvo* **12,** 558–61; *Chem. Zentr.* **1927,** II, 1525; cf. *Neftyanoe Khozyaistvo* **12,** 414.—The ozocerite dissolved in benzine is heated 1.5 hrs. at 60–5°, with sulfosil (activated silica gel). The part not retained is ceresin. Applied to crude ozocerite, the method gives higher contents of ceresin than does the method of Lach (Die Ceresinfabrikation 60(1911); *C. A.* **5,** 2533), but applied to ozocerite from which the volatile components have been removed the method gives lower contents of ceresin than does the Lach method. In the Lach method, which employs a temp. of 200°, light hydrocarbons, which are not absorbed by the sulfosil, are lost, but on the other hand the removal of resin from the ozocerite is more complete by sulfosil. Silica gel and Florida earth absorb less than sulfosil because they retain especially the resins already present, which accelerate only slightly the polymerization of unsatd. compds., while sulfosil polymerizes and retains all substances which form resins. If ozocerite is treated first with silica gel and then with sulfosil, resins, compds. tending to form resins, and ceresin can be sepd. C. C. Davis

Analysis and purification of sulfate turpentine. I. Y. Postovskii and V. G. Plyusnin. *Ann. inst. polytech. Oural* **6,** 245–59(1927).—The authors have investigated the possibilities of purification of raw turpentine oil obtained as a by-product in the tech. prepn. of cellulose by the sulfate method. Such turpentine contains considerable quantities (10–12%) of methylmercaptan, methyl sulfide and of other mercaptans and sulfides, which all must be removed before turpentine can be used for chem. and other purposes. As possible methods of purification P. and P. suggest a careful oxidation of the impurities. A method which can be more advantageously employed in technic is a fractionated steam distn. Distn. of 15% of the raw material removes 86% of all impurities yielding a ppt. with $HgCl_2$. On distn. of 50%, only 2% of mercaptan, etc., remain in the turpentine. These last traces are preferably oxidized by a very weak soln. of chlorinated lime. The oil so purified has the following consts.: 90% boils between 153.5° and 165°, d_{15} 0.8645; n_D^{20} 1.4672; Br no. 2.0. About 45% of the purified oil boils between 153° and 155° and consists of practically pure α (and β) pinene. G. B. Kistiakowsky

Report of Committee D-7 on timber. HERMANN VON SCHRENK, *et al. Proc. Am. Soc. Testing Materials* (preprint) **75**, 8 pp.(1928).—The Com. recommends that the tentative method for distn. of creosote oil (D 246–267) be adopted as standard with slight revision as to asbestos cover. A slight change is recommended in creosote sp. gr. detn. in the standard method of sampling and analysis of creosote (D 38-27). The comm. is coöperating with the Bur. of Standards in the prepn. of a table for correcting the d. and vol. of creosote and creosote coal-tar mixts. from observed temp. to standard temp. These detns. are being made by the Bur. in 100 ml. pycnometers. The temp. is detd. with Pt resistance thermometers and the bath is thermostatically controlled to within 0.005°. Readings range from 40° to 100° in 10° steps. The calcd. av. rates of vol. change per 1° at range 40° to 50° and at range 70° to 90° are: creosote 0.00071 and 0.00075, resp.; creosote coal-tar soln. 0.00070 and 0.00072; water gas-tar creosote 0.00073 and 0.00076; water gas-tar soln. 0.00071 and 0.0075. Interpolated tables are being prepd. An historical résumé of expansion coeffs. used in the U. S. is included.
ALFRED L. KAMMERER

Studies in gas generator tar from wood. I. YA. POSTOVSKII, N. A. APOLLOV AND B. P. LUGOVKIN. *Ann. inst. polytech. Oural* **6**, 241–4(1927).—The authors have carried out a partial analysis of tar obtained in an industrial gas generating plant mainly from wood of conifers. This tar is characterized by its high content in water (50%) and in resinous substances insol. in ether (up to 40%). Besides *p*-cresol and *p*-ethyl phenol, 2 other phenols were isolated, one of which, not identified, has m. p. 234–235°, C 72.87%, H 6.24%; the other is probably derived from dimethoxy-*p*-xylene. A hydrocarbon $(C_8H_6)_n$ has also been isolated. It is unsatd., gives a blue-color reaction with cold, and a green one with warm, H_2SO_4, being sol. in both, has an odor similar to that of naphthalene, is of greenish yellow color; m. 87–88°. It is suggested that this hydrocarbon belongs to the group of fulvenes, being perhaps $C_{16}H_{12}$, naphthylfulvene.
G. B. KISTIAKOWSKY

Cracking petroleum oils. JOSEPH G. ALTHER (to Universal Oil Products Co.). U. S. 1,685,476, Sept. 25. The oil is passed through a coil of progressively decreasing size in a heating zone in which the diam. of the coil decreases in accord with a lowering temp. in the heating zone; the oil is discharged from the smallest portion of the coil into a vapor chamber from which vapors may be led to a dephlegmator and condenser. An app. is described.

Recovery of gases and vapors from petroleum. ROBERT T. OSBORN (to Standard Oil Co. of Calif.). U. S. 1,685,501, Sept. 25. Gases such as those produced by distg. petroleum and which are substantially uncondensible at atm. temp and pressure are passed (unaccompanied by vapors condensible at or below the pressure and temp. at which the gases can be condensed) into vapors from a distg. unit operating below cracking temp. and pressure to convert high b.-p. oil into vapors which are condensible at atm. temp. and pressure and which contain substantially no constituents of which the gases are composed. A vapor condition is thus created such that substantially all of the vapors and gases can be condensed at atm. temp. and pressure, without change in the mol. state of the gases, and condensation is then effected. An app. is described.

Paraffin from petroleum. EVERETT R. WILES. U. S. 1,684,426, Sept. 18. In order to recover amorphous paraffin of high m. p. from petrolatum, the latter is treated with a mixed solvent contg. acetone 35 and C_6H_6 65%, and the soln. formed is cooled and the paraffin sepd. from it.

Continuous counter-current system for treating petroleum with acid, alkali or other immiscible reagents. RALPH A. HALLORAN (to Standard Oil Co. of Calif.). U. S. 1,684,489, Sept. 18. An app. is described.

Cracking hydrocarbons. Eugene H. Leslie and Edwin M. Baker. U. S. 1,684,771, Sept. 18. Superheated hydrocarbon vapors from a vapor phase cracking plant are conducted into the lower part of a fractionating column and brought into counter-current contact with a liquid condensate. A substantial portion of the vapors leaving the column are refluxed into its upper part and used in the counter-current treatment. An app. is described.

Cracking hydrocarbon oils. E. S. Andrews (to B. Ormont Associates, Inc.). Brit. 285,199, Dec. 11, 1926. Oil under treatment, after partial vaporization (suitably in a tube furnace) is brought into a portion of the app. (which is described) where steam is being generated, to effect vaporization and cracking of the heavier ends of the oil. Cracking temps. and pressures may be used and the furnace tubes may be formed of alloys contg. Si, Fe and in some cases Ca, which have a catalytic action in forming light hydrocarbons.

Cracking hydrocarbon oils. H. Carroll. Brit. 284,345, Jan. 28, 1927. Oil is heated in pipe coils in a furnace to slightly below the cracking temp., the vapor produced is sepd. from liquid in a dephlegmator and the liquid is then further passed to a converter or cracking app. comprising a series of heated annular troughs filled with fusible metal or alloy and over which the oil successively flows as it descends on the exterior of a heated truncated cone on which the troughs are mounted. Various features of app. are described.

Cracking hydrocarbon oils. Lyman C. Huff (to Universal Oil Products Co.). U. S. 1,685,488, Sept. 25. Oil is continuously passed in a restricted stream through an elongated conduit such as a pipe coil within a furnace and a superheated inert gas or vapor such as superheated steam is introduced into successive sections of the conduit under pressure and velocity greater than those of the oil stream, to "step up" the flow of the oil stream through the conduit. An app. is described. Cf. *C. A.* **21,** 1348.

Cracking hydrocarbon oils. C. P. Dubbs. Brit. 284,507, April 29, 1927. Oils are heated under pressure in tubes in a furnace, to a cracking temp., and are then passed to a reaction chamber under reduced pressure, when vapors pass to a dephlegmator and condenser. Incondensible gases are further heated, in a sep. furnace, to a temp. higher than that at which the oil was first heated and then injected into the liquid in the reaction chamber. The app. is described. Cf. *C. A.* **22,** 2462.

Conversion of hydrocarbon oils. Carbon P. Dubbs (to Universal Oil Products Co.). U. S. 1,686,654, Oct. 9. A mass of relatively heavy hydrocarbon oil is heated to a cracking temp. above the b. p. of the complex chem. constituents of the heavy oil under sufficient pressure to prevent vaporization of these constituents; this heated oil is then introduced into a zone of lower pressure in such manner as would permit vaporization of the constituents mentioned and dissocn. of the oil is checked by regulated introduction of a cooler mass of hydrocarbon oil into contact with the heated oil substantially at the point of its vaporization. An app. is described.

Converting hydrocarbon oils to oils of lower boiling point. Frederick Lamplough. Can. 283,681, Oct. 2, 1928. The oil is mixed with a normally solid cyclic hydrocarbon as naphthalene and heated to 300° to 400° under a pressure higher than the vapor pressure of the oil at the temp. employed, then cooled to a temp. such that the heavier portion of the hydrocarbons will remain in a liquid state but the lighter portion formed will be vaporized upon release of the pressure. Then the lighter hydrocarbons are sepd.

Purifying hydrocarbon oils. Warren K. Lewis (to Standard Oil Development Co.). U. S. 1,686,493, Oct. 2. Oil is agitated with fuller's earth or other suitable adsorbent material in a succession of units (of an app. which is described) and the oil is passed successively from one unit to another; the oil is then removed from the adsorbent material and the latter is washed with naphtha, dried by a current of naphtha vapor, steam or other hot gaseous drying fluid; and fresh adsorbent material is supplied to replace spent washed and dried material.

Distilling hydrocarbon oils. Frank A. Howard (to Standard Oil Development Co.). U. S. 1,686,490, Oct. 2. A distn. vessel is heated by contact with molten material such as Pb or its alloys during operations such as distn. and cracking and as soon as the distn. is completed the vessel is moved out of contact with the molten heating material.

Oil refining. Sijbren Tijmstra (to The Simplex Refining Co.). Can. 283,795, Oct. 2, 1928. Hydrocarbon oils are treated with an alkali metal plumbite in a water soln.; the plumbite soln. is sepd. from the oil; the oil is treated with an alkali metal polysulfide; and then the polysulfide soln. is removed. Cf. *C. A.* **22,** 4242.

Fuel oil from liquid residuum of hydrocarbon oil distillation. Wayne S. Hughes

and JAMES HARROP (to Standard Oil Development Co.). U. S. 1,686,491, Oct. 2. The liquid residue obtained from distg. petroleum after adding NaOH or similar processes may be emulsified with water and gas oil, the emulsion afterward broken by addn. of acid material such as H_2SO_4 and the aq. layer contg. inorg. matter to be sepd. is withdrawn from the layer of oil. An app. is described.

Nitrogenous bases from hydrocarbon materials. HARRY K. IHRIG (one-half each to Sumner E. Campbell and Associated Oil Co.). U. S. 1,686,136, Oct. 2. A crude gasoline such as may be obtained from first distn. of a petroleum oil is treated with a reagent such as 25% H_2SO_4 to form compds. with the nitrogenous bases present, the reaction products are sepd., *e. g.*, by counter-current flow, and are made alk. and subjected to distn. to sep. nitrogenous bases of 2 types, sol. and insol. in water, and these are then sepd. from each other by their differential solubilities. They may be used in *insecticides* or for other purposes. Cf. *C. A.* **22**, 2661.

Catalytic or other production of liquid hydrocarbons. F. J. M. HANSEN. Brit. 284,224, Jan. 24, 1927. At. H is caused to act upon C or upon hydrocarbons such as vapor of naphthalene (which need not be pure), without pressure and with or without use of a catalyst. The H may be dissocd. by an elec. arc or hot spark discharge and used immediately after its dissocn.

Reclaiming oil. GEORGE L. CHERRY (to The DeLaval Separator Co.). Can. 283,744, Oct. 2, 1928. Used oil contg. water and solid impurities is heated to nearly the boiling point of water and mixed with 1–3% solid NaOH. It is settled while hot to ppt. the impurities; the supernatant oil is drained off, clean water is added and the last traces of solid impurities and NaOH are removed by centrifuging.

Causing flow of oil through pipe lines. LOUIS W. SOUTHGATE. U. S. 1,686,475, Oct. 2. The oil is sucked along at one end of a section of the pipe line, air or gas is permanently removed from the system, and the oil is forced along the next section. An app. is described.

Preventing oxidation of oils by air. F. HOFMANN and M. DUNKEL. Brit. 284,616, Nov. 24, 1925. To protect oils such as those used for lubricating or in transformers from action of air, especially when the oil is heated, they may be mixed with 0.1% of urea or with small quantities of other suitable basic org. N compds. such as bases, nitriles, oxamides and derivs.

Extracting oily bases from crude shale oil. DAVID T. DAY. U. S. 1,685,315, Sept. 25. A body of crude shale is first treated with a dil. inorg. acid soln. such as H_2SO_4 and the acid soln. contg. the oily bases is sepd. from the oil and neutralized with lime or other suitable alkali to effect pptn. of the bases, the oily bases are collected apart from the alk. soln., the pptd. bases are treated with an inorg. acid and the resultant mixt. is treated with an alkali to effect neutralization and is agitated with a hydrocarbon solvent such as gasoline and the resulting soln. is drawn off from the alk. aq. soln. and the oily bases are extd. from the soln. with H_2SO_4, HCl or other suitable inorg. acid soln.

Apparatus for gravity separation of oil from water. DEUTSCHE WERFT A.-G. Brit. 285,350, Feb. 25, 1927.

Gas separator for crude mineral oil. A. G. KHARNASON. Russ. 4347, Jan. 31, 1928.

Detergent preparations from mineral oils. G. S. PETROV. Russ. 4300, Sept. 15, 1924. Sulfonic acids obtained from mineral oils or crude oil distillates are sapond. with caustics or NH_3 or alkali carbonates with or without the addn. of fats or fatty acids.

Reconditioning electric insulating mineral oil. CLARENCE J. RODMAN and MAX HECHT. U. S. 1,685,681, Sept. 25. The oil is evacuated and then treated with an adsorbent such as prepd. charcoal, SiO_2 or a filter clay which also has been evacuated; this treatment is effected out of contact with atm. gases and the oil is then filtered to remove the adsorbent while still maintaining it out of contact with atm. gases. An app. is described.

Improving motor fuel. ALLGEMEINE GES. CHEM. IND. M.B.H. Fr. 635,570, June 7, 1927. Gasoline is fractionally distd.; the fraction distg. up to 160° is sepd. (part A); and the fraction distg. above 160° is extd. with agents, such as liquid SO_2 or acetone, which dissolve to a great extent the unsatd. but not the satd. hydrocarbons. The extg. agent is sepd. and this fraction added to part A.

Filter for internal-combustion motor fuel. SOCIÉTÉ ANON. DES NOUVELLES INVENTIONS MÉCANIQUES ET ÉLECTRIQUES. Fr. 635,161, Sept. 30, 1926.

Material for preventing detonations in internal-combustion engine cylinders. E. SOKAL. Brit. 285,145, Nov. 11, 1926. A carbonate of Pb, Cu, Ca, Mg, Na or K

(or a substance which is converted into one of these carbonates during the operation of the engine) is mixed with a binder such as a silicate and used for coating the walls of engine cylinders or the heads of pistons. Several coatings may be successively applied and baked. Cf. *C. A.* **21**, 3454.

Transformation of methane into gasoline or the like. ACHILLE GOUDET. Fr. 32,666, May. 26, 1926. Addn. to 613,146. Methane is treated with Ni, Fe or Co or their compds. at a pressure up to 1000 kg. per sq. cm., the migration of the H being facilitated by the addition of alkali or alk. earth metals or of Cl, Br, I, S, Se, Tl. The methane may be mixed with Hg vapor and submitted to an elec. field giving a difference of potential.

Vent pipe and associated liquid seal for gasoline storage tanks, etc. HAROLD V. ATWELL (to Standard Oil Co. of Ind.). U. S. 1,685,516, Sept. 25. Structural features.

Coating for gasoline tanks. H. H. EVANS. Brit. 285,149, Nov. 11, 1926. A coating for the exterior of tanks is formed of glycerol 39.5, fish-glue 48, glucose or molasses 1.5 and water 11 parts.

Tape formed of paper or other "soluble" material, for use in measuring the depth of wells in well drilling. CLINTON H. M. BULL (to Reed Roller Bit Co.). U. S. 1,686,-956, Oct. 9. In use, a tape formed of paper or other "sol." material is used which after use disintegrates in the oil or water in the well.

Fat-like products from sapropelites. D. A. SHVEDOV. Russ. 4161, Sept. 15, 1924. Sapropelites are oxidized by HNO_3 or other oxidants.

Removing amorphous wax and asphaltic material from oil. THOMAS CLARKSON and HAMMOND R. HEAL. U. S. 1,686,437, Oct. 2. A light petroleum distillate is added in sufficient quantity to lower the viscosity of the oil and the soln. is then refrigerated to cause solidification of a substantial portion of the amorphous wax and asphaltic material; the soln. is filter-pressed through material of a texture at least as fine as that of filter paper and after solidified material has accumulated on the filtering medium it is removed by a hot solvent.

Slack wax. BENJAMIN L. SOUTHER and WILLIAM A. GRUSE (to Gulf Refining Co.). U. S. 1,685,008, Sept. 18. A magma of solid slack wax contg. oil is comminuted to a fluent consistency and the liquid and solids are mech. sepd., *e. g.*, by pressing.

Slack wax. BENJAMIN L. SOUTHER and WM. A. GRUSE (to Gulf Refining Co.). U. S. 1,685,058, Sept. 18. Solid slack wax is comminuted to a fluent consistency and a solvent liquid such as *n*-BuOH is added which has a preferential solvent action on the oil; solid components and liquid components of the material are then mech. sepd. from each other, *e. g.*, by filter-pressing or centrifuging.

Rotating device for testing lubricants. ARMEN E. BECKER. U. S. 1,686,365, Oct. 2. An elec. device is provided for detg. the thickness of the oil film under different pressures, etc.

Edge filter for lubricating oil, etc. METAL EDGE FILTER CORP. Brit. 285,127, Nov. 9, 1926. Structural features.

Filter sheets made of fabric for filtering lubricating oil of engines, etc. C. W. MCKINLEY (to A. C. Spark Plug Co.). Brit. 284,982, Feb. 5, 1927.

Asphalt emulsions. W. H. SCHMITZ. Brit. 284,330, Jan. 29, 1927. Asphalt emulsions are prepd. with use of alk. solns. of bleaching powder or bleaching powder residues from lubricating oil refining or the like. Other acid or alk. residues from oil refining, as well as stabilizers such as starch, gums or soap may be added, and the materials are heated in forming the emulsions.

Apparatus (with a retort mounted on trunnions) for carbonizing and distilling wood. RAPHAEL MALBAY. U. S. 1,684,875, Sept. 18. Connections are provided for burning gas led from the retort in an annular chamber surrounding the retort.

Distillation of wood. HERMANN SUIDA. Austrian 109,173, Nov. 15, 1927. The distn. products are freed from tar and treated in the vapor phase with cresol or other high-boiling solvent for AcOH, the treatment being carried out in a column at a temp. above 100°. The residual vapors are cooled to 70–90° to remove water and traces of acid and solvent, and are then further cooled to condense the wood spirit.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Progress in the cellulose industry. WALTER PETERS. *Apparatebau* **40**, 218–9 (1928).—A brief outline of improvements in methods and equipment. J. H. MOORE

Röntgen spectrographic observations on cellulose. R. O. HERZOG AND W. JANCKE.

Kaiser Wilhelm Inst. für Faserstoffchemie. *Z. Physik.* **49**, 27–30(1928); cf. *C. A.* **22**, 3986.—The well-known splitting of certain spots in the fiber pictures of cellulose is shown to be due to the exptl. set-up and not to a distortion of the cellulose lattice or a second component. Pictures taken with very narrow defining holes and with a monochromatic beam, deflected from a calcite crystal, show no such splitting. Using a narrow slit for the rear definition and a circular hole for the forward definition of the beam, the equatorial spots are split when the fiber axis is perpendicular to the slit, and the vertical spots (the sample being inclined to the beam) are split when the specimen and slit are in the same plane. Thus divergence and heterogeneity of the beam are the causes of this splitting. The indentity period is 10.35 A. U. R. L. HERSHEY

X-ray methods in determining structure of cellulose fibers. Organomolecular investigations. O. L. SPONSLER. Univ. of Calif., Los Angeles. *Ind. Eng. Chem.* **20**, 1060–2 (1928).—A general agreement, based largely on x-ray studies, has been reached with respect to the character of the structure of cellulose. The long, primary valence chains appear to be well established, but agreement has not been reached with regard to some of the details. Many of the difficulties are due to the fact that the natural fibers have a gross structure, the result of their growth, which makes it impossible to obtain reflections from any one set of planes considered crystallographically and from these planes alone. The best that can be done is to arrange the fibers as nearly parallel as possible into a small bundle 3 or 4 mm. thick. A section 3 or 4 mm. long is then cut from this bundle, and used as the sample for x-ray study. By mounting this on a protractor, the x-ray beam may be passed through this at known angles with reference to the fiber axis. A complete set of diffraction patterns consists of about 10 photographs taken at different angles. Conclusions as to the compn. of planes must take into consideration the intensities of the lines, but such conclusions are in some doubt because of the many factors involved. A. W. KENNEY

The self-recording strength tester. FRITZ RÜHLEMANN. *Papierfabr.* **25**, Tech.-Wiss. Teil 577–81(1927).—The Rühlemann app. for detg. the tensile strength, stretch and elasticity of single fibers photographically is described. J. L. PARSONS

Remark on the note: New light on the form of molecules of cellulose and polymers by J. R. Katz and P. J. P. Samwel. R. O. HERZOG. *Naturwissenschaften* **16**, 673 (1928); cf. *C. A.* **22**, 3986.—Barton and Hunt (*C. A.* **19**, 753) have already made expts. in agreement with the recent results of K. and S., finding a complex of less than 10 A. U. size. B. J. C. VAN DER HOEVEN

Changes in cellulose induced by acid sulfite treatment. ERIK HAGGLUND AND F. W. KLINGSTEDT. Woodchem. Inst. Åbo. *Svensk Kem. Tids.* **40**, 181–8(1928) (In German).—Cotton was digested in sealed tubes at 130° with sulfite liquor contg. 45% SO_2 and 0.8% CuO. Tubes were opened at hourly intervals for analysis. Ash in the fiber increased from 0.2 to 5.1%. The Cu no. increased from 1.2 to 3.9. α-Cellulose decreased 43% the first hr. and 27% the following 14 hrs. 1.9% sugar was found in the liquor. More sugar would have formed had the liquor been more acid. Cotton autoclaved in 8% $NaHSO_3$ and 0.2 *N* HCl gave a fiber product with 2.1 Cu no. and 76% α-cellulose. 1.6% sugar was found in the liquor. This prepn. pptd. from NaOH soln. by AcOH and redissolved by NH_3-NaOH-$Cu(OH)_2$ gave the same $-\alpha_D^{20}$ curve as Hess' cellulose A (*C. A.* **18**, 1384). H. and K. concur in conclusions of Hess with respect to formation and identity of cellulose A and α-cellulose. A. R. ROSE

The prolonged action of caustic soda solution on cellulose and its practical and theoretical importance. R. HAZARD. *Russa* **3**, 245–51(1928).—A brief review. A. PAPINEAU-COUTURE

Present status of our knowledge of the intimate structure of cellulose fibers. R. MICHEL-JAFFARD. *Chimie et industrie* **19**, 801–8, 1003–12(1928).—A review with bibliography of 53 references. A. PAPINEAU-COUTURE

Hydrated cellulose. JOSEPH ROSSMAN. *Paper Trade J.* **87**, No. 7, 61–2(1928).—A review of U. S. pats. relating to the gelatinizing or hydrating of pulp by mech. and chem. means. A. PAPINEAU-COUTURE

The action of ultra-violet rays in the bleaching of cellulose. RENÉ ESCOURROU. Papeteries Navarre. *Chimie et industrie* **19**, 989–97(1928).—The action of ultra-violet rays on paper pulp in hypochlorite bleaching, H_2O_2 bleaching, treatment with 4% NaOH and treatment with 5% H_2SO_4 was investigated, the expts. being carried out on strong unbleached sulfite, soft unbleached sulfite, easy-bleaching sulfite, sulfite pulps prepd. from knots and from wood flour, uncooked pulp sepd. from good fibers in the rifflers, and spruce groundwood. The effects of the rays were estd. by detg. the Cu no., α-cellulose and in some cases β- and γ-celluloses. The presence of ultra-violet rays in bleaching with H_2O_2 or in the treatment of pulp with dil. NaOH or H_2SO_4 is

without effect; in $CaOCl_2$ bleaching it considerably increases the Cu no. and β- and γ-cellulose contents, and reduces the α-cellulose content. In the knot pulp presence of ultra-violet light did not exert a deleterious action, even in $CaOCl_2$ bleaching, presumably because the Cl reacts more readily with the ligneous constituents than with the cellulose; but the wood flour pulp and raw pulp were considerably deteriorated by $CaOCl_2$ bleaching in the presence of ultra-violet rays. A. PAPINEAU-COUTURE

Kress process of bleaching kraft pulp. O. KRESS. *Paper Trade J.* **87**, No. 9, 47–8(1928).—A description of U. S. pats. 1,645,061 (*C. A.* **21**, 4069) and 1,651,530 (*C. A.* **22**, 868). A. PAPINEAU-COUTURE

A micro-method for the determination of the copper number of cellulose. T. F. HEYES. *J. Soc. Chem. Ind.* **47**, 90–2T(1928).—The Braidy method (cf. *C. A.* **15**, 2360) gives better check detns. than the Schwalbe method for Cu no., and avoids the danger of auto-reduction. This method has been adapted to use a 0.25-g. sample of material. The solns. used are: (I) 150 g. Na_2CO_3 + 50 g. $NaHCO_3$; (II) 100 g. $CuSO_4.5H_2O$; (III) 40 g. $Fe_2(SO_4)_3.9H_2O$ + 100 cc. concd. H_2SO_4; each is made up to 1 l. with distd. H_2O. The sample is weighed into a test tube, which is fitted with a Pb wt. and closed with a glass pear; 9.5 cc. of I and 0.5 cc. of II are mixed, heated to boiling, and added to the sample. The tube is heated in a covered, boiling water bath for 3 hrs. with occasional stirring; pulp and Cu_2O are then collected in a Jena or Gooch crucible, and washed. The Cu_2O is dissolved with a total of 2.5 cc. of III, washed out of the pulp with 2 cc. portions of distd. H_2O, and the reduced Fe titrated with 0.04 N $KMnO_4$, a 2-cc. micro-buret graduated in 0.005 cc. being used. The end-point change, from pale green to colorless, is quite sharp. Blanks av. 0.025 cc. The results are in excellent agreement with those of the macro-method, on samples ranging from 0.20 to 4.58 Cu no. Such a micro-method has several advantages, especially for the *textile* chemist. R. H. DOUGHTY

Esterification of cellulose and cellulose esters. I. Velocity of nitration of cotton fiber. KATSUMOTO ATSUKI AND MASANORI ISHIWARA. Tokyo Imp. Univ. *Proc. Imp. Acad.* (*Japan*) **4**, 382–5(1928).—The nitration of cellulose as a fiber is governed 1st by the diffusion of the mixed acid, and 2nd by the progressive nitration of the HO groups in the mol.; the velocity of the nitration as well as the formation of the Me_2CO-sol. cellulose nitrate is expressed by formulas. **II. Decrease in viscosity of cellulose nitrate with the duration of nitration.** *Ibid* 386–8.—Cellulose nitrate gives a soln. of a lower viscosity as the time of nitration is increased; the relation between the decrease in viscosity and duration of nitration is expressed by the formula: $(a - y_1) = ae^{-Kz(c-nz)}$, where a is the assumed viscosity of the cellulose nitrate when the nitration period $z = 0$, $a - y_1$ is the viscosity obtained after the nitration for a period z, c and n are the consts., K is the velocity const. It is supposed that the decrease in viscosity is mainly caused by the depolymerization of the mol. aggregate of the nitrate during nitration. C. J. WEST

Investigation of the stability of cellulose esters. A. CAILLE. *Mon. produits chim.* **9**, No. 95, 5–8; *Chem. Zentr.* **1927**, II, 2542; cf. *C. A.* **22**, 2269.—Expts. on acetylcellulose esters are described, including their prepn., the purification of the acetylsulfonic acid esters with EtOH, lime water and distd. water, and their stability upon heating to 180°. Detns. were made of the free, combined and neutralized H_2SO_4, and of the total, free and combined AcOH. Very favorable results on stabilization were obtained by heating the esters for 1 hr. at 120° in an autoclave. C. C. DAVIS

Recent developments in solvents and plasticizers for cellulose esters. AUGUST NOLL. *Papierfabr.* **25**, Tech.-Wiss. Teil, 497–501(1927).—The phys. consts. and applications of the following compds. as solvents and plasticizers for cellulose esters are given: Me and Et glycols and their acetates, diethyl and Et Bu carbonates, Me and Et glycol esters of *o*-phthalic acid, Ph_2CH_2, Ph_2O, $MeC_6H_4SO_3Ph$, $PhCH_2OH$, *n*-PhEtOH, MeCOPh, $PhCH_2OAc$, amyl ester of salicylic acid, $MeC_6H_4SO_2NHPh$, 2,3-hydroxynaphthoic acid anilide. J. L. PARSONS

Cellulose formate. I. Formation [from hydrocellulose and cellulose regenerated from viscose]. Y. UEDA AND K. HATA. *Cellulose Ind.* (Tokyo) **4**, 1–2(1928).—Hydrocellulose with anhyd. formic acid and H_2SO_4 yields a product contg. 22.90% of formic acid (theory for monoformate 24.21%), while the product from cellulose regenerated from viscose contains 50.50% (cellulose triformate requires 56.09%). The ester is readily sol. in pyridine, but only sparingly sol. in other org. solvents. Results showing the effect of variations in the amt. of H_2SO_4 on the degree of esterification are given. B. C. A.

Constitution of cellulose xanthogenate. TH. LIESER. Techn. Hochschule München. *Ann.* **464**, 43–55(1928).—After attempts to synthesize cellulose xanthogenate (I)

from alkali cellulose and CS_2 failed, it was found that a pure product could be obtained by digesting the impure I with abs. pure MeOH; details are given of this method of prepn. The pure I retains the structure of the original cotton and has a very pale yellow color. Numerous analyses confirm the formula, $C_6H_{10}O_5.C_6H_9O_4.OC(:S)SNa$, thus supporting the view of Karrer and Vieweg and disproving the original view of Cross and Bevan. Using varying amts. of CS_2, at temps. from 0 to 22°, for 3–8 hrs., the resulting I showed S contents from 13.2 to 15.7 and Na from 7.7 to 8.3 (theory, S 15.1 and Na 5.45). While the pure I appears to suffer no change in 8% NaOH after 11 months yet there is a change of the cellulose into cellulose A, as indicated by its soly. in alkali and the Cu no. The same change takes place in the dry I on standing for 120 days. I with I gives the disulfide, pale yellow. MeI reacts with I, giving a product with scarcely any Na, about 33% of the original S content and with about 25% of the theory of Me content. $PhCH_2Cl$ behaves similarly. Metallic derivs. were obtained with $Cd(NO_3)_2$, $ZnSO_4$, $NiSO_4$, $CuCl_2$, $CrCl_3$, $FeSO_4$; $HgCl_2$ gives a *complex*, $I.2HgCl_2$.

C. J. West

Acetylation of cellulose with pyridine and acetic anhydride. Kurt Hess and Noah Ljubitsch. Kaiser-Wilhelm-Inst. Chemie, Berlin-Dahlem. *Ber.* **61B**, 1460–2 (1928).—All the methods hitherto known for the acetylation of cellulose (I) involve the use of catalysts (acids, salts of weak bases with strong acids, $ZnCl_2$-AcOH) which may themselves under certain conditions exert a powerful (hydrolytic) action on the I, and the conclusion has been reached that acetylation of I without an accompanying hydrolysis is impossible, but H. and L. have devised a method in which the hydrolytic influence is reduced to a min. or entirely done away with. The I fiber, purified as usual, is allowed to stand in 4 or 2 *N* NaOH (depending on whether it is a natural or an artificial product) for 1 hr. or 30 min., washed with H_2O to complete the disappearance of the alk. reaction, allowed to stand in excess of dry C_5H_5N which is renewed until the H_2O in the fiber has been displaced by the C_5H_5N, pressed as free as possible of the C_5H_5N, shaken 24 hrs. at room temp. with 10 parts Ac_2O and 16 parts C_5H_5N and finally placed in a bath at 40–5°. The temp. is gradually raised to 70° but it is possible that this is not necessary. The velocity of acetylation varies with the I. Viscose and Cu silk take up about 52.5% AcOH in 5 days and the reaction is complete or nearly complete (62.7% AcOH) in 30 and 34 days, resp. The cotton sample used took up about 40% AcOH in 5 days and this increased to 54.5% in 43 days (in another expt. 61.5%). Cellulose was almost completely acetylated in 52 days (61.1%). The resulting products were yellowish, the structure of the fibers was intact; after washing they could not be distinguished in color or appearance from the original material. Those contg. the quantity of AcOH calcd. for triacetylcellulose were, unlike all triacetylcelluloses hitherto described, completely or almost completely insol. in org. solvents. They swell to a limited extent in $C_2H_2Cl_4$, $CHCl_3$ and C_5H_5N. It should be remembered, however, that triacetylcellulose solns. are micellar in nature and represent the end stage or nearly the end stage of transitions from limited to unlimited swelling, so a difference in this respect must by no means have to be ascribed to a chem. difference. H. and L. are inclined to believe that the "insoly." of their triacetylcellulose is due to the complete preservation in it of the micellar structure of the original I. Probably the almost complete lack of dispersibility in org. solvents especially is also due to the fact that no products of acetolysis are formed in the reaction; numerous observations in the chemistry of I and related substances show that strikingly small quantities of foreign substances, if uniformly distributed, may have a great influence on the dispersibility.

C. A. R.

Cellulose sulfuric acid esters. Wilhelm Traube, Brune Blaser and Carl Grunert. *Ber.* **61B**, 754–67 (1928).—If well-dried cellulose (I) is placed in an atm. contg. a small quantity of SO_3 vapors, it combines, without charring, with 3 mols. of the SO_3 to form acid *cellulose trisulfate* (II), $(C_6H_7O_5(SO_3H)_3)$, which can readily be isolated in the form of well-characterized salts stable in the air. Detectable quantities of the acid mono- or di-sulfate are not formed even when the quantity of SO_3 present is far less than 3 mols. for each $C_6H_{10}O_5$ complex; the I not converted into II is recovered unchanged. Inversely, when more than 3 mols. SO_3 are present, there is at first formed only II, which then adds more SO_3, presumably in the same way that SO_3 adds to H_2SO_4 to form $H_2S_2O_7$; if the products are at once worked up in H_2O the excess of SO_3 is quantitatively split off as H_2SO_4. The products which have absorbed only about 3 mols. SO_3 can be cautiously neutralized directly with cold KOH; if more SO_3 has been absorbed it is better to dissolve in H_2O and remove the H_2SO_4 with a slight excess of $Pb(OH)_2$ or $PbCO_3$ and the Pb with H_2S and then neutralize with KOH. The exceedingly fine flocculent ppt. is centrifuged off, dissolved in a little warm water and allowed to

stand at 0°. The neutral *K salt A* (III), $C_6H_7O_5(SO_3K)_3$, so obtained (yield, about 65%) contains 12–4% H_2O which can be driven off at 100° in a high vacuum; it is tasteless, easily sol. in hot H_2O, in about 20 parts at 0°, is pptd. from H_2O by KOH as a greatly swelled mass, is insol. in EtOH and other org. solvents, shows under the ultramicroscope in water the characteristics of a colloidal soln., is completely amorphous both under the microscope and on x-ray examn. Its Cu no. (the no. of g. of Cu which 319 g. of anhyd. III ppts. as Cu_2O from a boiling alk. Cu soln.; on account of its great stability toward alkalies, the salt is practically unchanged by boiling with Fehling soln.; this Cu no. measures the reducing power of the salt itself, not of I split off from it) is 2.5–4.0 as detd. by the Schwalbe method by boiling 5 min. with Fehling soln. In water it shows $(\alpha)_D -5.5°$ to $-6.5°$, reacts neutral and can be boiled for a long time without change but in the presence of HCl gradually splits off H_2SO_4 quant. with formation of dark solns. having a strong reducing power corresponding to that of glucose solns. Toward alkalies it is very stable; even at 150°, KOH splits off only very little H_2SO_4. Its solns. give no ppt. with $AgNO_3$, a slight ppt. with $Pb(OAc)_2$ but an abundant ppt. with basic Pb acetate. $BaCl_2$ gives a ppt. sol. in dil. HCl. Nitron forms a difficultly sol. salt. On dry heating, III carbonizes to an exceedingly voluminous mass. Concn. of the mother liquors of III gives, in varying yields, a *salt B* (IV) of the same compn. but more sol. and *d*-rotatory; $(\alpha)_D$ 1° to 7°. III seems to be homogeneous but IV is probably a different salt contaminated with varying quantities of III. Its Cu no. is 8–9. In view of its method of formation at room temp. in a "dry" way, II is believed to be an ester derived from I in the same way as the known I esters of other inorg. and org. acids, a view supported by the properties of II and III (slight reducing power, amorphous character, slight rotatory power, colloidal aq. soln. Cond. detns. on III gave values ranging from 41.6 for V 32 to 80.2 for V 2048, the increase in dissocn. in soln. being accompanied by an increase in disaggregation. Attempts to regenerate I from II have thus far failed. Alkalies attack the II only slightly and although acids split off the H_2SO_4 quant., they do so only on heating and very gradually and the C residues undergo deep-seated decompn. at the same time. In the analysis of III it was noted that prepns. which, from their compn., must have contained K_2SO_4 did not give the usual test for SO_4 ions on treatment in acid with $BaCl_2$, and expt. showed that the pptn. of $BaSO_4$ from HCl solns. of sulfates by $BaCl_2$ can within certain limits be prevented by the previous addn. of II (*e. g.*, a mixt. of 10 cc. 0.04 *N* H_2SO_4, 0.1 g. III, 1 cc. of 12% HCl and 8 cc. 0.1 *N* $BaCl_2$ gave a slight turbidity only after 36 hrs.). III similarly prevents the pptn., within certain limits, of numerous other difficultly sol. compds. (PbI_2, $AgCrO_4$, $HgCrO_4$). If the quantity of III added to certain solns. well-crystd., not very difficultly sol. substances is such that crystn. is not wholly prevented but only retarded, the habit of the crystals is often (*e. g.*, with tartaric acid or $KClO_4$) changed. If samples of filter paper which have been treated with an excess of SO_3 are not worked up at once but are allowed to stand (protected from moisture) they become, in the course of 1 or more days, transparent and finally change to a homogeneous, brown, transparent, viscous mass which with aq. KOH yields products very easily with approx the compn. $C_6H_6O_5(SO_3K)_4$. A salt of such a compn. is without doubt no longer a deriv. of I; in its formation a new HO group doubtless has been formed by opening of a ring in the mol. of the anhydrosugar and at the same time the assocn. between the original mols. of the I has been, if not completely destroyed, at least greatly diminished. The new salt has a Cu no. of about 30. In the prepn. of the above substances, it is not necessary to start with pure cellulose; they can be obtained from wood shavings. C. A. R.

Benzylcellulose and its applications. L. Clément and C. Rivière. *Chimie et industrie* **Special No.**, 670–2(April, 1928).—See *C. A.* **22**, 3293. A. P.-C.

The action of strong sodium hydroxide solutions on cellulose. P. Waentig. *Papierfabr.* **25**, Fest- und Ausland Heft 112–5(1927).—Cellulose in strong NaOH solns. (17.5%) changes very little even after an immersion of 30 days; on the other hand, cellulose which is immersed in strong alkali soln. and then allowed to "age" dissolves more readily in alkali. Its soly. increases up to 30 days when an equil. is apparently reached. At the end of a 30 days' immersion of sulfite pulp its α-cellulose content was 78.6%; after a similar time of aging the α-cellulose content of the same pulp was reduced to 57.2%. The immersion figure for cotton was 97.7%, while its aging figure amounted to 79.2% for the same length of time. The β-cellulose content of these materials is correspondingly increased whenever there is a decrease in the α-cellulose, so that the sum of the two remains practically const. A microscopical study of these two effects produced by alkali indicates that the fiber is not morphologically homogeneous. Aging causes its breakdown to fibrillae. The assumption is made that O of the air plays a role in the aging phenomenon. J. L. Parsons

The action of concentrated nitric acid on cellulose (as determined by x-ray methods). K. R. Andress. *Z. physik. Chem.* **136**, 279–88(1928).—The action of HNO_3 of about 1.42 sp. gr. on cellulose gives addn. compds., $2C_6H_{10}O_5.HNO_3$ (I) and $2C_6H_{10}O_5.2HNO_3$ (II). The latter was prepd. by Knecht (*Ber.* **37**, 551(1904)) and has been shown by Katz and Hess (*C. A.* **21**, 1358) to give hydrocellulose on regeneration with H_2O. It is shown by A. that both compds. give the same x-ray diagram, a monoclinic system of the dimensions; a = 12.20 A. U.; b = 10.28 A. U.; c = 9.73 A. U.; β = 53° 7'. Hence I is an addn. compd., II an adsorption complex of I and HNO_3. Cellulose itself gives: a = 8.35 A. U.; b = 10.28 A. U.; c = 7.96 A. U.; β = 78°. The addn. of HNO_3 is accompanied by enlargement of the lattice in one direction only, the 0 0 2 and 1 0 1 planes being unaffected. R. H. Doughty

Graphical evaluation of nitrating acids. Artur Benda. *Chem. Obzor* **2**, 129–32; *Chem. Zentr.* **1927**, II, 1776.—A graphical method which is described has been tested in the operation of a *cellulose factory*. It is applicable to other processes. C. C. D.

Modern solvents and softening agents for nitrocellulose, celluloid and acetylcellulose. A. Noll. *Papierfabr.* **25**, Tech.-Wiss. Teil 65–73(1927); cf. *C. A.* **22**, 867.—An address in which the newer nitrocellulose solvents and plasticizers are described. Cyclohexanol acetate is preferable to amyl acetate as a solvent. Me hexalin acetate, a mixt. of 3 isomeric hexahydrocresols, is similar to cyclohexanol acetate in solvent power. J. L. Parsons

Oxidation of alkali-cellulose with gaseous oxygen. II. Wilhelm Weltzien and Gerhard zum Tobel. *Ber.* **60B**, 2024–32(1927); cf. *C. A.* **20**, 3806.—Evidence is cited that the reaction of alkali-cellulose with O_2 (air) may be of little significance. Cotton and hydrated cellulose (cuprammonium silk) were allowed to swell in NaOH solns. of concns 10–50% by vol. The excess of NaOH was pressed out and the mass exposed to O_2, the absorption being detd. at intervals. With increasing NaOH concn. the O_2 absorption increased and was slightly greater in the cuprammonium silk. This absorption increased up to 30% NaOH concn. and reached an equil. in 15 days. Alkali consumption amounted to more than $^2/_3$ of the O_2 absorbed [$C_6H_{10}O_5 + 6\ O_2 + 12\ NaOH = 6\ Na_2CO_3 + 11\ H_2O$]. Decreased reactivity at higher NaOH concns. is suggested as due to further compd. formation between the cellulose and the NaOH. With the same concn. of NaOH soln. the degree of O_2 absorption varied with the hydration and amt. of NaOH retained by the fibers after compression. The products of the oxidation are yellow to brown in color and gelatinous in nature, generally sol. in NaOH When the yellow colored solns. were acidified large amts. of CO_2 were evolved and the alkali-sol. cellulose was pptd. as a white, voluminous mass, which was difficult to filter and possessed a Cu no. 1.93. The major portion of the oxidation products are sol. The ratio between the alkali consumption and the O_2 absorption in 2 expts. with 30% NaOH soln. was const. Simple oxidation products are formed comparatively rapidly. Even with the max. amt. of O_2 absorbed very little chemically changed cellulose is left. The reaction of alkali-cellulose in an atm. of N_2 is different. Indications are that one portion of the cellulose is far more reactive than another. J. L. Parsons

Hemicelluloses. Emil Heuser. *Papierfabr.* **25**, Tech.-Wiss. Teil 238–43(1927).—The chemistry of hemicelluloses is reviewed in an address. Methods for the detn. of hemicelluloses are purely conventional and the results lack uniformity. β-Cellulose from sulfite pulp consists of 78.16% cellulose, 13.68% xylan and 5.64% mannan. Depolymerized cellulose appears as the chief constituent and the pentosan content is greater than the hexosan content. In γ-cellulose these same constituents are present. Alk. exts. of sulfite pulp yield Cu-alkali compds. similar to cellulose. Such compds., as for instance the xylan Cu-alkali compd., of the compn. $(C_5H_8O_4)_2.Cu(OH)_2.(NaOH)_2$, are bright blue in color, are sol. in NH_4OH, decompose on drying, giving a green coloration, and tend to depolymerize the polysaccharide. The $Cu(OH)_2$ is assumed to decompose, forming Cu_2O and O which oxidizes the cellulose or hemicellulose complex. The formation of such compds. indicates a similarity between cellulose and the hemicelluloses, which vary greatly depending upon the nature of the cellulosic material. J. L. Parsons

Viscosity determination on wood cellulose. L. Rys. *Chem. Obzor* **1**, 83–6; *Chem. Zentr.* **1927**, II, 1419.—Dissolve 3 g. cellulose in 100 cc. ammoniacal standard Cu soln. in an atm. of indifferent gas. Det. the viscosity of the clear soln. by measuring the time of fall of a glass or steel ball (diameter 3.3 mm.) through a column 15 cm. high at a definite temp. Detailed directions are given. The accuracy is ±15%. J. S. Reichert

Carbohydrate constituents of the easily hydrolyzable hemicellulose of pine. Erik Hägglund, F. W. Klingstedt, Truls Rosenqvist and Helmut Urban. Inst. for

Wood Chem., Åbo, Finland. *Z. physiol. Chem.* 177, 248-63(1928).—The hemicellulose of pine wood consists of an easily and a difficultly hydrolyzable portion. If the wood is hydrolyzed by heating under pressure with mineral acid a sugar results which comes partially from the cellulose. Only by diminishing the H-ion concn. by buffering, as is the case with sulfite acid ($NaHSO_3$ in H_2SO_3) can the hemicellulose alone be brought into soln., and then only its easily hydrolyzable portion. Analysis of the sugar thus obtained in the sulfite liquor takes for granted that the lignosulfonic acid has been successfully removed. By pptn. with α-$C_{10}H_7NH_2$ it is not possible to effect a quant. sepn. Subsequent treatment of the sugar soln. with EtOH and charcoal yields a soln. which contains nearly all the sugar in a pure state. Pptn. of lignosulfonic acid entails a considerable decrease in reducing power which indicates a certain reducing power on the part of lignosulfonic acid. In order to det. whether glucose is present in the sugar of sulfite liquor, the mannose must first be pptd. as the hydrazone. After liberation of the residual sugar with BzH, glucose was satisfactorily demonstrated. Glucuronic acid was not present in this sugar fraction. The presence of glucan in the easily hydrolyzable hemicellulose of pine is thus shown. Mannose, galactose and fructose were also demonstrated. On the basis of rotation of the fermented sugar soln. arabinose as well as xylose may be present. Galacturonic acid was found in the EtOH-insol. fraction. If this acid is derived from a hitherto unknown wood pectin, the amt. of such pectin, assuming it to be similar to beet pectin, is estd. at 0.7% of the wood substance. The compn. of the easily hydrolyzable pine hemicellulose, which comprises 18% of the wood, is, after hydrolysis, 1[illegible] pentoses, 42.7% mannose, 4.2% galactose, 3.2% galacturonic acid, 4.0% fructose and 28.9% glucose. A. W. Dox

The preparation of cellulose from agricultural by-products. Umberto Pomilio. *Pulp Paper Mag. Can.* 26, 1293-6, 1324(1928); cf. *C. A.* 22, 1038.—An address discussing the advantages and possibilities of the Cl gas process for the production of pulp from cereal straws and similar agricultural waste products. A. P.-C.

The chemistry of lignin. Georges Dupont. Institut du Pin, Bordeaux. *Pulp Paper Mag. Can.* 26, 1183-8, 1235-7, 1254-8, 1267-8, 1297-1300, 1326(1928).—See *C. A.* 22, 3291. A. Papineau-Couture

Spirit for combating celluloid fires. K. Hauck. *Zentr Gewerbehyg. Unfallverhüt.* 14, 293; *Chem. Zentr.* 1927, II, 2467.—In case that a wet, raw celluloid mat catches fire on the cylinders, the fire loses its explosive character if alc. is poured on the material at the beginning of the fire. Quiet flames develop which can be easily smothered with covers of asbestos. G. Schwoch

The ripening of viscose. J. Frenkel. *Cellulosechemie* 9, 25-6(1928).—A new theory for the ripening of viscose is presented which, in contrast to the usual view, does not admit a polymerization of the cellulose to the xanthogenate during ripening. F. considers viscose as a system of 2 colloids, the xanthogenate and the cellulose; for on sulfidizing alkali-cellulose, dicellulose xanthogenate is formed first, which on continued ripening is hydrolyzed and decompd. into its constituents CS_2, NaOH and cellulose. Proof of this hypothesis was given by the following expt.: A mixt. of 3 l. viscose and 750 g. pressed, regenerated cellulose, obtained from 1 l. of the same viscose by pptn. with N H_2SO_4, was dispersed in Plausons colloid mill for a short time with NaOH. Before the expt. the viscose had a degree of ripening C_z = 2.8, 7.8% cellulose and 7.09% NaOH; after the expt. C_z = 3.9 with a cellulose content of 7.55% and NaOH 7.09%. In this manner a ripe viscose was obtained from an unripe viscose with a considerable saving of time. L. C. Fleck

Change of plasticity of viscose with ripening. K. Atsuki, T. Takagi and T. Ohta. *Cellulose Ind. Tokyo* 3, 317-20(1927).—Measurements of the rate of flow of a viscose contg. 7% of cellulose and 7.78% of NaOH, carried out in a modified Ostwald viscometer at 25° under pressures of from 3 to 25 cm. of Hg, after ripening the material at 25° for various times from 53 to 240 hrs., show that viscose has a slight but measurable plasticity, since the flow rate-pressure curve at a lower pressure is convex to the pressure axis, giving a yield value. As ripening proceeds, the yield value becomes smaller, reaches a min. at 121 hrs., and again increases. It is supposed that the disperse phase, at first a continuous system, becomes less continuous by dehydration with the ripening, but that after max. dehydration, when the yield value is a min., it begins to coagulate, forming a firm continuous system giving a yield value. The disperse phase, before and after min. plasticity is reached, is more or less continuous, but differs in rigidity. In the former case it is easily deformable through being highly hydrated, while in the latter it is rigid on account of the formation of micelles of highly hydrated particles. B. C. A.

The recovery of volatile solvents in the manufacture of artificial textiles. J. H.

BRÉGEAT. *Chimie et industrie*, Special No., 687–96(April, 1928).—A discussion of the necessity of the recovery of volatile solvents in the manuf. of artificial textiles from the economic and sanitary standpoints. It is shown that absorption by such materials as activated charcoal and SiO_2 gel is uneconomical as well as dangerous on account of fire hazard. As regards absorption by scrubbing with a liquid that exerts merely a solvent action or that reacts chemically with the vapors, absorption of alc.-Et_2O by H_2SO_4 or of alc.-Me_2CO by $NaHSO_3$ or absorption of either mixt. by H_2O is shown to give a very low yield, while recovery by absorption in cresol gives a high yield in both cases. A. PAPINEAU-COUTURE

Determination and significance of the alkali soluble constituents in artificial silks. W. WELTZIEN. Textilforschungsanstalt Krefeld. *Papier-Fabr.* **25**, Fest- und Ausland Heft 66–71(1927).—Max. soly. of artificial silks and chem. wood pulp exists at a concn. of 10% NaOH; even with a 9% alkali soln. the differentiation between these substances is more pronounced. Cuprammonium silk is the most resistant to alkali, being sol. to the extent of about 30%; viscose is sol. 40–50% and nitrosilk is practically completely sol. in 10% NaOH. J. L. PARSONS

The preparation of artificial silk. A. MÜLLER. *Z. ges. Textilind.* **30**, 450; *Chem. Zentr.* **1927**, II, 1419.—Potato flour, decomposed with Diagum from the Diamalt-A. G., Munich, produces a flexible, strong fiber. Avimalt from the same firm is recommended for softening artificial silk. J. S. REICHERT

Artificial silk, the various processes of manufacture, and its properties. D. G. ZWARTZ. *Indian Textile J.* **37**, 266–7, 302–3; *Chem. Zentr.* **1927**, II, 1419.—A brief description of nitro, Cu, viscose and acetate silk. J. S. REICHERT

Acetate silk. R. O. HERZOG. *Papier-Fabr.* **25**, Tech.-Wiss. Teil 17–8(1927).—An address covering the chemistry of acetate silk manuf. The secondary acetate is made from the primary by mineral acids of medium concn., strong org. acids, or other compds. The primary acetate is a triacetate, possesses a particle size similar to the original cellulose, and is sol. in $CHCl_3$ and other halogen-contg. compds. The secondary acetate shows an Ac content between that of the tri- and diacetates. Its particle size is 0.5–0.2 that of the original cellulose and in the larger size it is sol. in Me_2CO and MeEtCO. The smaller size is sol. in esters. This acetate dissolves in non-solvents (C_6H_6, EtOH) after the addn. of solvents, the difference in soly. depending chiefly on the no. of free OH groups as well as on the particle size. J. L. PARSONS

Nitro and acetate silk. I and II. FRANZ REINTHALER. *Seide* **32**, 226–8, 258–60; *Chem. Zentr.* **1927**, II, 2525.—Data on the properties of cotton cellulose, the prepn. and properties of collodion wool, the prepn. of cellulose acetate, the properties of secondary cellulose acetate, and the prepn. of the spinning soln. from collodion wool and from cellulose acetate. C. C. DAVIS

Technic and economics of the American rayon industry. H. JENTGEN. *Papier-Fabr.* **25**, Tech.-Wiss. Teil 97–102(1927).—An address covering recent developments in the American rayon industry. American sulfite pulp is superior to European pulp for viscose manuf. Pulp contg. a very high α-cellulose content is generally undesirable if the value is over 90%; the viscosity may be less than with a pulp contg. a higher hemicellulose content. Such a low viscosity cannot be effectively corrected by shortening the ripening time or by reducing the temp. A sulfite pulp of a definite hemicellulose content is apparently necessary, in contrast to cotton. Pulps freed from such impurities do not yield superior threads. Viscose rayon is not pure α-cellulose but contains relatively large amts. of hemicelluloses, NaOH and CS_2. A portion of the hemicellulose content appears highly dispersed in the alk. soln. and becomes a sludge in the pptg. bath. A pulp which had been purified by 5 mercerization treatments did not yield a superior thread compared to an untreated pulp and the viscosity of the former viscose soln. dropped to 6–8, whereas the latter was 18. J. L. PARSONS

Testing sulfite liquor. ERWIN SCHMIDT. Mannheim-Waldhof. *Zellstoff u. Papier* **7**, 56–7(1927).—The iodate method for detg. free SO_2 is practically just as sensitive toward weak acids as the NaOH titration in the presence of phenolphthalein. With cooking liquors contg. org. acids greater precision cannot be obtained with the iodate method than with Höhn's method. Expts. with the iodate-iodide method in which the amt. of water was the only variable showed that by increasing the vol. of the latter the amt. of thiosulfate required for the titration decreased. J. L. P.

The dehydration of sulfite spirit with quicklime. E. SCHLUMBERGER. *Papier-Fabr.* **25**, Tech.-Wiss. Teil, 180–3(1927).—Com. sulfite spirit should not have a water content greater than 0.7% when mixed with C_6H_6 as a motor fuel. Data from 58 expts. relating to the dehydration of com. sulfite spirit under atm. pressure, in an autoclave under pressure, and in the vapor phase by means of CaO, are tabulated. Increasing

the temp. 10° doubles or triples the speed of dehydration. The size of the lime particles has little influence on the reaction. For best results 125% of the theoretical amt. of CaO required should be used. Using this CaO twice gives an EtOH yield in excess of 95%. About 10% of CaO is converted to $Ca(OH)_2$. The estd. time for dehydration to 0.5% water content when EtOH vapor is passed over CaO at 100° is 15 sec. contact. Non-aq. impurities, aldehydes, etc., are not removed during the dehydration process. J. L. PARSONS

Recent experiences in the evaluation of the waste sulfite liquors. I and II. G. TESCHNER. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* **3,** 17–21, 157–62; *Chem. Zentr.* **1927,** II, 1878.—A discussion of the most important and promising procedures for utilizing the waste liquors, particularly for the production of *sugar, tanning agents, pitch, disinfectants, coal dust* briquets, fuel from the concd. liquors and various other valuable products in addition to sulfite charcoal. J. S. REICHERT

The utilization of waste sulfite liquor for fertilizer purposes. J. GÖRBING. Forschungsanstalt für Bodenkunde und Pflanzenernährung, Rellingen in Holstein. *Papier-Fabr.* **25,** Tech.-Wiss. Teil, 573–5, 633–8, 653–8, 671–3(1927).—Bokorny [*Mitt. deut. Landwirtschaftgesellschaft* **1919**, 6 et seq., No. **16,** 202 et seq.(1920); cf. *C. A.* **13,** 1531] has published results which are very favorable to the use of waste sulfite liquor as a fertilizer. These results are not confirmed by G. in a series of extensive tests with waste sulfite liquor used in various ways as a fertilizer and with different plants. In many instances negative results were obtained or no improvement in plant growth was observed. There are 9 illustrations of growing plants. J. L. PARSONS

Contribution to the history of sulfate pulp manufacture. L. J. DORENFELDT. *Papier-Fabr.* Fest- und Auslands-Heft **1928,** 97–107; *Paper Ind.* **10,** 809–13(1928).—Directions for the process as outlined by the inventor, C. F. Dahl, in 1884, are given, with cooking curves and a sketch of the digester used. R. H. DOUGHTY

Pulp mill waste recovery methods. J. B. C. KERSHAW. *Paper Trade J.* **87,** No. 6, 61–2(1928); cf. *C. A.* **22,** 1040.—A review. A. PAPINEAU-COUTURE

Photomicrographing ground pulp. E. OMAN AND B. SEGRING. *Svensk Pappers-Tid.* **31,** 438–41(1928).—Photomicrographs of fibers colored with the following dyes are shown: rhodamine R extra, fuchsin and HCl, safranine, chloramine black and alum, and carbon black G under 4 different conditions. Dye solns. were of 1% strength and the dyeing was done directly on the prepn. glass. W. SEGERBLOM

Recent bleaching processes for pulp. J. FUNCKE. *Papier-Fabr.* **25,** Tech.-Wiss. Teil, 221–8(1927).—A review of American patents covering processes for bleaching pulp fibers during the last 10 years. J. L. PARSONS

Bleaching sulfite pulp. RAGNAR BERGQVIST. *Svensk Pappers-Tid.* **31,** 361–3, 397–9, 434–8(1928); cf. *C. A.* **22,** 1679.—The chemistry of the bleaching process is explained on the basis of exptl. and theoretical considerations, especially the effect of variations in the H-ion concn. of the bleaching liquor. Free Cl does not bleach sulfite pulp. The hypochlorite ion gives the best bleaching effect. *A new method for detg.* p_H is based on Wulff's Folien-Colorimeter and gives p_H values from 2.6 to 9.0 within ±0.1 error. The measurement can be made in turbid or strongly colored solns. A membrane is used, permeable to aq. solns. and contg. an indicator color which diffuses much more slowly than the H or OH ion and which changes color in proportion to the p_H value. A comparison scale shows the colors for each 0.2 p_H from 2.6 to 9.0. Artificial light may be used. A 3 cm. testing strip is stirred for 1–2 min. in the soln. to be tested and then compared with the standard. If the soln. is turbid, strongly colored or contains colloidal substances, the testing strip may be quickly rinsed with distd. water or pressed between filter paper. The detn. of p_H requires skill, particularly if much active Cl or free acid is present. The conditions for bleaching control samples are described in detail, 2 tables of numerical data and 2 graphs showing the results of 14 detns. The theoretical discussion of the above results starts with equations showing oxidizing and chlorinizing action of CaClOCl, the oxidizing action increasing with the alk. character, and the chlorinizing action increasing with the acid character of the soln.; it continues with a study of the dissocn. reaction and consts. involved, and concludes with a table giving the relation between the concns. of free Cl and of HClO, and that between HClO and the hypochlorite ion calcd. from 8 samples in a 0.1106 *N* CaClOCl soln. Similar measurements are made for a 0.034 *N* CaClOCl soln. The relations between the concns. of free Cl and of HClO, as well as that between HClO and the hypochlorite ion, are detd. for 8 samples at the Cl diminishing coeff. 31%. These relations are discussed. B. concludes that the hypochlorite ion plays the important part in industrial bleaching, that free Cl is injurious and that HClO has very little bleaching power. Controls for all above detns. were

obtained by 3 different methods, (1) the α-cellulose analysis, (2) the Cu no. and (3) the viscosity method. Unbleached cellulose gave α-cellulose 87.6%, β-cellulose 3.6%, ash 0.42%, Cu no. 2.08%, viscosity 32.0 and resin 1.17%. These values for each of 14 samples are tabulated and discussed. W. SEGERBLOM

Bleaching sulfite pulp at higher consistencies. ERNST HOCHBERGER. *Papier-Fabr.* **26,** Fest-und Auslands-Heft 66–88(1928).—The subject is considered from both the theoretical and practical standpoint, with especial reference to the relations existing in the first stage of 2-stage bleaching. Sixteen tables of data and 17 figures are presented. There is no advantage in going above 15–18% consistence, so far as time is concerned. Better results are obtained with pulps of average (10–16%) bleachability than with very hard or easy-bleaching pulps. With such average pulps it is best to bleach in 2 stages, the first at low temp. and high consistence, the second at low consistence and higher temp.; holding the second stage at high consistence, or bleaching in 3 stages, is poor practice. There is an optimum amt. (33–48% of the bleachability value on pulps bleaching at < 10 and > 20%, resp.) of bleaching agent for the first stage. Under the best conditions, 25–33% bleaching agent, and 33% time may be saved over the 1-stage low-consistence bleach. *Bleachability* here is defined as the amt. of bleach powder, contg. 33.3% active Cl_2, consumed in bleaching at 5% consistence and 37° in 2 stages. With fairly easy-bleaching pulps, in the first stage: a good const. (k) is obtained when the rate of bleach consumption is calcd. as a second order reaction; there is a linear decrease of p_H (detd. with indicators in the thrice dild. soln.) during the reaction, down to about 6.5 at the end; chlorination (formation of sol. Cl compds.) during bleaching is least at the otherwise most favorable conditions of consistence and bleach ratio (cf. also Rys, *C. A.* **22,** 2271). Pulps which show variations in k and p_H from a regular course also show higher chlorination. Hence, variations in the course of the reaction are due to the increase of side reactions with respect to the true bleaching reaction of oxidation. The bleaching process appears to be governed, especially in the later stages, by the diffusion rate of dissolved incrustants. A great part of the bleaching agent used in the first stage goes to decomp. the incrustants present, these compds. being rendered sol. and removed in the second stage. Finally, good washing is necessary; care should be taken here to avoid a sudden drop in p_H, which would lead to repptn. of dissolved incrustants on the fibers. R. H. DOUGHTY

A new method of determining the color of bleached pulp. G. PORRVIK. *Svensk Pappers-Tid.* **31,** 466–9(1928).—Chalks of standard color, easily reproduced, are prepd. by mixing pharmaceutical chalk with $K_2Cr_2O_7$ soln. and evapg. to dryness. The chalks are graded according to $K_2Cr_2O_7$ content. A small amt. of English Red may be added, the amt. depending upon the red tinge of the class of pulp to be tested. The lightest colored sulfite pulps range from 0.4 to 0.5, and dark pulps as high as 1.60 have been tested. Sulfate pulps test about 2.50. The test is made by smearing pieces of chalk the size of a pea on the pulp sample until the proper match in color is found. W. SEGERBLOM

A rotating disk machine for measuring pulp color. CHESTER G. LANDES. Mead Fibre Co. *Paper Trade J.* **87,** No. 13, 48–50(1928); *Paper Mill* **51,** No. 39, 10, 39–40, 50(1928).—The Ives colorimeter is unsuitable for routine work, and because of various mech. defects its results are open to question. Disk machines as at present on the market are unsuitable for routine testing of pulp for color, for a no. of reasons which are given. It was improved by making all the disks alike and pasting varying sections of colored paper on them, which furnished a definite and quant. method of changing the difference between wheels and enabled other properties to be controlled more easily. The method of prepg. the disks is described. The accuracy, permanency, ease of reproduction of results and standardization of the instrument were detd. by means of tests. The instrument furnishes satisfactory comparable results for routine work under given conditions, provided its use is confined to the correct field and within its limitations. The latter are described and suggestions are made as to lines of research on methods of improvement and elimination of defects in the instrument. A. PAPINEAU-COUTURE

The danger of explosion in the manufacture of bleach liquors from liquid chlorine. E. SCHÖNBERG. *Papier-Fabr.* **25,** Tech.-Wiss. Teil, 581(1927).—An explosion resulted in a cast Fe tower covered with asphalt in which a $Ca(OH)_2$ soln. was treated with Cl_2, countercurrent flow. The cause is attributed to the supercooling of the mixt. owing to insufficient warming of the Cl_2 before passing into the soln. The decompn. of $Ca(OCl)_2$ to chlorate and chloride is without danger; the reaction $Ca(OCl)_2 = CaCl_2 + O_2$ occurs in an explosive manner, especially in the presence of such catalyzers as P, As, S, Fe_2O_3, etc. J. L. PARSONS

The explosion risk in the use of liquid chlorine for bleach liquor. H. KIRMREUTHER AND L. PURRMANN. Königsberger Zellstoffabriken und chem. Werke Koholyt. *Papier-Fabr.* **25**, Tech.-Wiss. Teil 698(1927); cf. preceding abstract.—A reply to E. Schönberg, in which the supposed cause for an explosion was the formation of solid $Ca(OCl)_2$ and its decompn. to O_2 and $CaCl_2$, is refuted from a chemical and a thermal standpoint. One kg. chlorine gas sets free 290.7 cal. in bleach liquor manuf. This heat warms the soln. as the heat of vaporization at 8° for 1 kg. Cl_2 is only 62.7 cal. J. L. PARSONS

The determination of the chlorine consumption number of pulps. A. EHRENFRIED. *Papier-Fabr.* **25**, Tech.-Wiss. Teil, 130–1(1927).—To 5 g. dry pulp (21 g. wet) add distd. water and sufficient bleach soln. to give 6% available Cl calcd. on the pulp. After 1 hr. at 20°, filter and test 50 cc. in the following manner: Add 20 cc. 0.1 *N* As_2O_3 and 3–5 drops Me orange indicator. Acidify with 10–15 cc. concd. HCl and titrate with 0.1 *N* $KBrO_3$ (2.7837 g. per l.) until the red color disappears. The comparative relation between the cc. of 0.1 *N* $KBrO_3$ and the Cl consumption no. is tabulated. J. L. P.

The determination of the copper number. CARL G. SCHWALBE. *Papier-Fabr.* **25**, Tech.-Wiss. Teil 157–60(1927).—S.'s Cu no. detn. and its numerous modifications are discussed. The alkali boil test of Cross and Bevan and the boil-off no. of Kaufmann for detg. cellulosic degradation products are also included. Seventeen references are listed. J. L. PARSONS

The influence of the fineness of pulp upon the copper number. K. G. JONAS. Techn. Hochschule, Darmstadt. *Z. angew. Chem.* **41**, 960–1(1928).—With the Schwalbe-Hägglund and Schwalbe-Braidy methods, it has been shown that pulp cut in 6 mm. squares gives results 20–50% higher than rasped pulp (cf. Gray and Staud, *C. A.* **21**, 2795). The best method of disintegration is to soak the pulp until soft, then shake vigorously with a few glass beads. This separates the fibers into a uniform suspension with a min. of mech. action. Prolonged shaking produces slime and gives variable results; 2 min. should be sufficient for complete disintegration. R. H. D.

The chemical properties and merits of summer and spring wood as raw material for the manufacture of sulfite pulp. E. HAGGLUND AND T. JOHNSON. *Pappers och Trävaru Tids. Finland* No. 20, 594(1926); *Papier-Fabr.* 25, Tech.-Wiss. Teil 22–3(1927).—From digestion expts. carried out with 30 g. wood and 150 cc. cooking acid in glass tubes, spring wood and summer wood were found to cook at about the same rates. Throughout the 3 series of tests the spring wood yielded liquors contg. less amts. of sugars than the liquors from summer wood, but the difference was small. The latter produced more AcOH and HCOOH. The pentosan, lignin and ash contents of the resulting pulps were similar. The stretch and tearing length were slightly inferior with pulps made from spring wood, while the fibers from summer wood appeared to be more brittle according to the folding test. J. L. PARSONS

Production of sulfite pulp. I. Cooking. L. RYS. *Chem. Obzor* **1**, 330–8(1926); *Chem. Zentr.* **1927**, II, 992.—Citing the modern literature, which is compiled as an index, R. gives a comprehensive survey of the methods used for cooking sulfite pulp. He discusses the chem. foundations of the cooking, and the compn. of the raw materials, as wood and sulfite liquor. Then he describes the hydrolysis and digestion of lignin, the influence of the p_H with regard to the constitution of lignin, the reaction and waste products formed, the possibility of controlling the reaction during the cooking and the use of the results gained from the cooking tests. G. SCHWOCH

Production of sulfite pulp. II. Bleaching. LAD. RYS. *Chem. Obzor* **1**, 364–8 (1926); *Chem. Zentr.* **1927**, II, 992; cf. *C. A.* **22**, 2271.—The bleaching of the sulfite pulp is briefly described and the possibilities of a further development are discussed. Citing the resp. literature, R. then mentions the chem. theories and the method of examn. of the chem. and mech. control, with reference to the newest processes. G. S.

Instrument control for sulfite pulp mills. REGINALD TRAUTSCHOLD. *Paper Trade J.* **87**, No. 2, 44–8(1928).—A discussion of the necessity and advantages of automatic indicating and recording instruments for controlling and regulating the operation of S burners, gas coolers, acid towers, digesters and pulp-prepg. equipment. A. PAPINEAU-COUTURE

Instrument control for soda and sulfate pulp mills. REGINALD TRAUTSCHOLD. *Paper Trade J.* **87**, No. 8, 38–42(1928).—A cursory review of the steps entailed in soda pulp production and their effective coördination into one continuous and repetitive process, pointing out the strategic utilization of instrument control. A. P. C.

Sulfate process patent review. JOSEPH ROSSMAN. *Paper Trade J.* **87**, No. 6, 57–9(1928).—A review of U. S. pats. A. PAPINEAU-COUTURE

The Wagner furnace (for black liquor recovery). C. L. WAGNER. *Paper Mill* **51**, No. 26, 16, 39(1928).—A description of the furnace and its operation. A. P.-C.

A mill scale demonstration of temperature control in sulfite pulping. G. H. CHIDESTER. Forest Products Lab., Madison, Wis. *Paper Trade J.* **87**, No. 15, 64–6 (1928).—The importance and advantage of following definite temp. schedules in cooking sulfite pulp to obtain optimum yield and quality have been shown by the lab. expts. of Miller, *et al.* The results obtained were applied to the production of sulfite from spruce and hemlock in an 80-ton mill. It was found that by following a definite predetd. temp. schedule the amt. of screenings was reduced by about 50%, the time required to run the stock out of the blow pits was increased by about 15–30 min., the yield was increased about 5% without addnl. cost of raw material or labor, the strength of the pulp was increased, the bleach requirements were reduced and both the strength and bleach requirements were made more uniform. The results were obtained with an increase of only 1 hr. in cooking time (from 8.5 to 9.5 hrs.). A. PAPINEAU-COUTURE

Mechanization of pulp cooking. LEO FRIEDLÄNDER. *Papier-Fabr.* **26**, 474–5 (1928).—An automatic *relief-valve for sulfite digesters* is described. R. H. DOUGHTY

Effect of temperature on sulfite cooking. ERIK HÄGGLUND. *Pappers och Trävaru-Tids. Finland* No. **12** (1928); *Papier* **31**, 717–25(1928).—Other cooking conditions being equal, a yield of 55% of pulp contg. 7–8% lignin can be obtained with max. cooking temps. of 120–35°. When the max. cooking temp. is carried to 135°, delignification occurs so rapidly that it is difficult to stop the cook at exactly the proper moment, while this can easily be done with max. temp. of 120°, which constitutes the advantage of low-temp. cooking. In the stages where the pulp has a Br no. of 0.15–0.30 (yields of 52–48%), it makes no difference whether the max. temp. is 120° or 135°, the pulp yields and their Br nos. being the same and the pulps having practically the same strength when beaten to the same degree in both cases. With rapid cooking (max. temp. 145°), however, conditions are different, the pulp being of lower quality and the yield for the same degree delignification about 3% lower. The rate of delignification is approx. doubled by increasing the cooking temp. 10°. Temp. was found to have relatively little influence on the acidity, sugar content of the liquor and production of H_2SO_4. A. PAPINEAU-COUTURE

The sulfur dioxide, heat and volume balance in relief liquor and gas in sulfite pulping. G. SOLTAU. *Papier-Fabr.* **26**, 550–4(1928).—The relations are analyzed to show the SO_2 recovery and associated heat losses in various stages of a representative direct-steam cook. About 1% of the total heat used in cooking is lost with the relief gas, 10–12% with the relief liquor. This may advantageously be used in preheating the cooking acid. Nomographs show the relation of relief gas compn. to digester temp. and pressure, also the interrelation of strength and volume of tower and cooking acid, S consumption and SO_2 recovery. R. H. DOUGHTY

Swelling-power measurement on unbleached sulfite pulp. W. NIPPE. Koholyt A.-G., Sackheim. *Papier-Fabr.* **26**, 501–6(1928).—The degree of swelling of a pulp is distinct from its swelling power. The latter property has been studied as a possible means of technical evaluation. Samples of 1–2 g. were dried at room temp. over P_2O_5 *in vacuo*, then exposed to a current of air at 80% relative humidity and 30° until const. wt. was reached. The amt. of H_2O taken up by 100 g. pulp under these conditions is termed the *swelling no.* The equil. requires 2–3 days for establishment; there is an hysteresis effect in approaching equil. from dry and wet pulps. Repeated drying at room temp. does not affect the values, nor does storage for 9 months. The values are readily reproducible with an absolute error of 0.075%. Values range from 10.5 to 13.6 for ordinary pulps, 6.77 for Guignet (hydro) cellulose. Oxycellulose gives a slightly decreased value. Swelling no. of pulp parallels Cl consumption (Sieber) and also depends on the type of cook (direct or indirect). Drying at high temp. may cause a large variation. Swelling is probably due to hemicelluloses present. The results are directly opposite to those of the D'Ans and Jager method (*C. A.* **20**, 819) using 15% NaOH, and in poor agreement with the Schwalbe strip method using H_2O (*C. A.* **19**, 174, 3017). The former is due to chem. effect, the latter to adhesion of H_2O. Use of swelling no. and Cl absorption value together gives an improved measure of pulp quality. R. H. DOUGHTY

The acid resistance of bronzes in sulfite pulp mills. HERBERT RAUCHBERG. *Papier-Fabr.* **25**, Tech.-Wiss. Teil 473–7(1927).—Thirty-nine metals were suspended 2–3 weeks in a sulfite pulp digester contg. a soln. in which 4.65% free SO_2 was present at the beginning of the cook. Cu lost 7.6% in wt.; Pb, 0.72%; Sn, 0.05%; while the Zn was completely dissolved. Sb was not attacked. The addn. of Zn to a bronze greatly reduces its acid resistance, and Sn and Pb raise its resistance. Addn. of 1.5% Sb increases the resistance of bronzes markedly. Sb and Pb behave in bronzes as if they were alloyed. The following limiting values are recommended for a good acid-

resisting bronze: Pb, 15–19%; Sn, 5–10%; Sb, according to the desired hardness 1–5%; and Cu, 66–75%. An Al bronze contg. 92% Al and 8% Cu was very strongly attacked by H_2SO_3. J. L. PARSONS

Effect of cooking time on pulp constants. I. CHINCHIN. *Zellstoff u. Papier* **7,** 235 (1927).—With the increase in the cooking time the lignin content (Willstätter and Krull method) of the chips decreases, the Cu no. (Schandroch and Häen-Low) increases, and the baryta resistance, the Cl factor (Tingle), and the amt. of Cl_2 (Sieber) required for bleaching are reduced. Decrease in total SO_2 of the cooking liquor resulted in an increase in the pentosan value for the pulp. The α-cellulose content was not affected by the cooking time but was affected by the strength of the acid. The resins remain practically the same but the ash decreased with the time. J. L. PARSONS

Electrical moisture measurements on sulfite pulps. E. SCHLUMBERGER. *Papier-Fabr.* **25,** Tech.-Wiss. Teil 81–3(1927).—The pulp sample is placed between metallic plates, which act as electrodes, under a definite pressure. The elec. resistance is measured and plotted against the water content of the pulp. No difference was observed when the sample was moistened with cond. water and with distd. water. The method offers a rapid means for detg. the moisture in pulps and may even be capable of development to a continuous recording device for control work. J. L. PARSONS

Alkali-soluble components of sulfite pulp and artificial silk. W. WELTZIEN. Textilforschungsanstalt Krefeld. *Papier-Fabr.* Fest- und Auslands-Heft, 115–20 (1928); cf. *C. A.* **21,** 2383.—The procedure used was to soak 0.5 g. of pulp in 30 cc. of NaOH soln. for 3 hrs., filter, wash 3 times with NaOH, treat with HCl, wash, dry and weigh. Increase of time up to 30 hrs. generally showed no significant increase of sol. material. The max. soly. of pulps is in NaOH of about 10% concn. As the time of treatment is increased, the max. approaches 10% concn. more closely. The decrease in soly. in concns. above 10% may be due to mass action effects. Artificial silk prepd. in different ways shows a similar, much greater max. soly. Nitrate silk is entirely dissolved in 10% NaOH. The colloid system "artificial silk" is distinguished from the system "pulp" by a relatively lower soly. in dil. and concd. alkali and much greater soly. in 10% alkali. The exptl. curves are reproducible; it has even been possible to identify an unknown pulp sample in this way. It is suggested that cellulose esters could most readily be studied or characterized by detg. the alkali soly. of the cellulose regenerated from them. R. H. DOUGHTY

Some fundamental principles underlying the manufacture of sulfite pulp. HAROLD HIBBERT. McGill Univ., Montreal. *Pulp Paper Mag. Can.* **International No.,** 125–7 (Feb., 1928); *Paper Mill* **51,** No. 6, 18, 20, 26(1928).—An outline of the work done under H.'s direction at the Forest Products Labs. of Canada and the Dept. of Cellulose and Industrial Chemistry of McGill Univ., on problems connected with the fundamental principles of sulfite pulping. The work of Campbell on SO_2 solns. (*C. A.* **21,** 1578; **22,** 1680), of Birchard on the action of cooking liquor on a variety of pulps and cotton fabrics (*C. A.* **21,** 4064; **22,** 684), and of Scarth on the penetration of wood fibers by liquids (*C. A.* **22,** 1852) is briefly mentioned. Unchanged lignin (*i. e.*, lignin in the same form as it exists in wood) can be extd. by heating spruce wood meal at 100–10° with ethylene glycol, glycerol or glycerol chlorohydrin, contg. a trace of I or of dil. HCl; which constitutes a radically new departure in the isolation of unchanged lignin. The mild chem. character of this method of extn. is clearly indicated by the fact that the hemicelluloses, pentosans and hexosans extd. in the process are obtained in a non-hydrolyzed condition, not having been converted into pentoses and hexoses. Sulfonic acids of unsatd. aldehydes analogous in compn. to lignin were found to be almost as strong as HCl or H_2SO_4, and ligninsulfonic acids very probably belong to the same category. It has been found that both satd. and unsatd. aldehydes, when treated with H_2SO_3 and bisulfites, yield strong acids, *viz.*, sulfonic acids, contrary to the generally accepted belief that the former yield sulfite esters and the latter a mixed sulfite ester-sulfonic acid. This investigation of the reactions of aldehydes is leading to a much better appreciation of the cause of "burnt cooks," and also of the mechanism of bleaching. Work is also being carried out on the properties of ring structures related to cellulose and on the problem of polymerization (nature of aggregate and degradation of cellulose). A. PAPINEAU-COUTURE

The Stebbins acid accumulator system for sulfite mills. T. L. DUNBAR. *Paper Trade J.* **87,** No. 8, 47–8(1928).—A description of U. S. pat. 1,646,084 (*C. A.* **22,** 165). A. PAPINEAU-COUTURE

Heat recovery system for sulfite mills. A. F. RICHTER AND F. A. AUGSBURY. *Paper Trade J.* **87,** No. 8, 49–50(1928).—A description of U. S. pat. 1,653,416 (*C. A.* **22,** 869). A. PAPINEAU-COUTURE

Developments in the preparation of calcium and magnesium bisulfite liquors. D. W. Steuart. National Research Council of Canada. *Pulp Paper Mag. Can.* **26**, 1013–6(1928).—See *C. A.* **22**, 3525. A. Papineau-Couture

Kinetics of the cooking reaction: experiments on the rate of cooking of straw by the soda process. R. Michel-Jaffard and A. Nicollet. Papeteries Navarre. *Chimie et industrie* Special No., 599–612(April, 1928).—A detailed description is given of a lab. investigation of the mechanism of cooking straw with NaOH under conditions approximating those of the com. manuf. of soda pulp. From a discussion of the laws of mono-, bi- and trimol. reactions, it is shown that the proportion of alkali consumed at the end of a given time is independent of the vol. of liquor in contact with the straw, or is proportional to this vol. or to its sq. according as the reaction is mono-, bi- or trimol. Under conditions similar to those used in com. practice, the consumption of NaOH follows the law of bimol. reactions during the stage of max. cooking temp. Assuming that the alkali combined to form easily hydrolyzable compds. may be considered as combined alkali, the disincrusting reaction is not limited by the reverse reaction. The greater proportion of the combined NaOH is consumed during the charging and bringing up to pressure of the digester, being 12–3% of the moist wt. of the straw in the expts. described. It seems probable that the consumption of NaOH at this stage is governed mainly by diffusion and convection phenomena, and that the constituents giving strongly hydrolyzable compds. (especially SiO_2) are practically completely dissolved at this stage. Though the effects of temp. were not studied, it is considered likely they follow the exponential law of homogeneous reactions once the bimol. rate of reaction has set in, as this rate supposes that the chem. reactions proceed at such a low rate that the effects of diffusion become negligible. The application of these results to the control of com. soda cooks is discussed. A. Papineau-Couture

Automatic device for the recovery of condensed steam in pulp mills cooking by the indirect process. Sainte-Martine. *Chimie et industrie* Special No., 619–22 (April, 1928); cf. Escourrou, *C. A.* **21**, 1547.—App. at present in use to protect the boilers in case the condensate should be contaminated with liquor has been perfected by providing that the valves are operated by small servo-motors instead of electromagnets, that the contaminated condensate is directly discarded while the pure condensate is sent to the boilers, the discarded and utilized condensates are metered separately, and in case of accident to the mechanism the whole of the condensate is sent to waste. A. Papineau-Couture

Semi-chemical straw pulp as a substitute for chemical and mechanical wood pulps. Umberto Pomilio. *Chimie et industrie* Special No., 639–61(April, 1928).—After discussing the inevitable shortage of wood which is bound to come as a result of the ever-increasing consumption of paper (particularly of news print) and showing that cereal straws and similar materials can furnish a practically inexhaustible supply of raw materials if the technical and economic conditions of its conversion into news print can compete with woods suitable for paper making, P. describes at length expts. and tests which he carried out on the production of news print from semi-chem. straw pulp. The pulp was prepd. by a very mild cooking at atm. pressure with dil. NaOH or H_2O, followed by washing and a treatment with Cl gas insufficient to effect complete chlorination. Paper made from 60–70% semi-chem. straw and 40–30% groundwood is as strong as ordinary sulfite-groundwood news print; but is somewhat more difficult to handle on high-speed rotary presses, but this defect could doubtless be overcome. Under present conditions in Italy, the cost of manuf. of semi-chem. straw pulp is of approx. the same order as the cost of groundwood, and only about 60% that of news grade sulfite. A. Papineau-Couture

The semi-sulfite process. C. C. Heritage, C. E. Curran, W. H. Monsson and G. H. Chidester. Forest Products Lab., Madison, Wis. *Paper Mill* **51**, No. 40, 9, 12(1928).—The semi-sulfite process consists of a mild pulping action employing the usual constituents of sulfite cooking liquor, but so regulating the conditions of temp., time, concn. and ratio of acid to chips that the chips, although thoroughly impregnated, are only softened and thus retain their original form, at the end of the reaction, to a large extent. The softened chips are "blown" from the digester as usual, are thoroughly washed, preferably with warm water, and are then mechanically disintegrated to a true pulp by suitable equipment. For this purpose the rod mill has been found satisfactory, although other types of refining equipment can possibly be used as well. From the results of tests carried out with such pulp it is concluded that: (1) It appears to offer a means by which a high yield of pulp suitable for news print and other grades of coarse paper can certainly be obtained from spruce and hemlock, and possibly from hard woods and mixts., and perhaps from some of the more resinous

species such as jack pine. (2) The yields obtained can be varied at will from 25 to 50% in excess of present mill practice. (3) A considerable saving can be effected in the time required for cooking. (4) A max. bursting strength of a pt. per lb. per ream or more can be obtained from the pulp. (5) Screenings can be eliminated, since the total digester charge is utilized. (6) Approx. cost estimates indicate an ample margin of saving over the addnl. power and fixed charges incurred by rod milling. (7) Difficulty in discharging the digester by its own internal pressure would probably develop at yields above 60–5%. The recent trend in mill construction toward the employment of gravity discharge after complete release of pressure appears to meet such a difficulty.
A. PAPINEAU-COUTURE

The problem of lignin. FRITZ ROSENDAHL. *Metallbörse* **17**, 2273–4, 2329–30, 2386–7; *Chem. Zentr.* 1927, II, 2745.—Methods for the *isolation and the decompn. of lignin* are discussed, with a few *constitutional formulas.* C. C. DAVIS

The behavior of lignin and lignin chloride in the preparation of pulp by the chlorine process. P. WAENTIG. *Z. angew. Chem.* **41**, 493–8, 977–80, 1001–5(1928).—A study of the Cl process has been made to show how to decrease the chemical consumption, especially in pulping wood, and to sep. the lignin in a readily recoverable and valuable form. The exothermic heat of the reaction between Cl and lignified fibers is 120–150 cal. per g. though Wenzl (*Hauptversamm. Ver. Zell- und Papierchem. und Ing.* **1926**) gives much lower figures. Sufficient moisture must be present in the material to avoid degradation due to the temp. rise and the HCl formed. When H_2O is used, the HCl formed amounts to about 70% of the Cl consumed, while when 15% HCl is used as chlorinating medium about 60% is so formed. This results in a lignin chloride higher in Cl, and hence more sol. The use of an alk. extn. before chlorination removes resins and wood gums, and so improves the chlorination and considerably reduces both the amt. of Cl consumed and the amt. of NaOH used in the subsequent extn. With wood, it is advantageous to carry out the pretreatment under pressure, though with bamboo, as with cereal straws, this is without value, treatment with NaOH at 100° being sufficient. Thus, spruce consumes a total of 42% Cl and 28% NaOH when the first alk. treatment is carried out at 100°, but only 24 and 21%, resp., when a steam pressure of 5 atm. is used. By using the same alk. liquor for preliminary treatment and subsequent extn. a further saving of 5% NaOH may be obtained. In working with wood, it is necessary to use shavings or crushed chips, since the temperature of chlorination is low and penetration correspondingly slow. This may prove a disadvantage in making *pulp for paper.* However, pulps prepd. exptly. from spruce in this way, bleached, beaten in a Lampén mill, and made into hand sheets gave tests of 7000–9000 m. breaking length and 1000–6000 double folds. Photomicrographs, several of which are included, show the fiber to compare favorably with spruce sulfite pulp. Contrary to generally accepted views, about half the lignin chloride formed is sol. in H_2O. This is partially hydrolyzed to Cl-poor compds. insol. in org. reagents. Under proper chlorinating conditions (50° and 20% HCl) the lignin chloride formed is sol. in alc. (sulfite spirit). These conditions are too drastic for practical work however. In the practical temp. range, increase in time or acid concn. results in increased alc. soly. of the lignin chloride. This suggests that the mechanism is similar to that assumed for the sulfite process, namely, formation of an addn. compd. with lignin, and subsequent hydrolytic sepn. of this compd. from cellulose, acidity being an important factor. By controlling moisture, time and acidity the process may be regulated. If a preliminary treatment with HCl is given, and the acidity during chlorination is kept low, the cellulose degradation is reduced, pulp of 90% α-cellulose being obtained from spruce. The isolated lignin chloride is sol. in NaOH, and less sol. at higher temps. It is pptd. by $Ca(OH)_2$, so this would not be a satisfactory extn. agent. The *lignin chlorides* isolated from spruce, beech, poplar, bamboo and wheat straw contain about 27% Cl, and give mol. wts. (by b. p. in Me_2CO) of 1000–1200, which agrees well with the Cross and Bevan formula (26.5% Cl, mol. wt. 1091) but it is improbable that this lignin chloride is a simple compd. **Remarks.** H. WENZL. *Ibid* 1008–9.—The heat values given by Waentig were from lab. expts., while those of Wenzl are from actual practice, and hence not comparable. **Reply.** P. WAENTIG. *Ibid* 1009. R. H. D.

Lignin acetal. II. ERIK HÄGGLUND AND HELMUT URBAN. Institute for Wood Chemistry, Åbo, Finland. *Cellulosechemie* **9**, 49–53(1928); cf. *C. A.* **21**, 4065.—Boiling isolated lignin such as HCl-, HCl-H_3PO_4- and alkali-isolated lignins with amyl and butyl alcs. in the presence of HCl causes 80% of the lignin to go into soln. in combination with the alc. in approx. stoichiometric relations. These lignins are very similar to those obtained directly from wood. The undissolved lignin residues also take up alc. but in smaller quantity. The authors purified alc. lignin from wood by pptn. from AcOH

and detd. the mol. wt. by lowering of the f. p. in AcOH. It was found to be about 400. This mol. wt. corresponds to a compd. with 2(OH)-, $2(OCH_3)$- and a(CHO) group. Accordingly, the formula for the basic mol. of lignin can be resolved as follows: $C_{19}H_{11}O_2(CH_3O)_2(OH)_2CHO$ (mol. wt. 396.3). These investigations show that alc. is not taken up by combination with tautomeric reacting OH groups of lignin.
L. C. Fleck

The problem of wood supply. R. Schuchhart. *Wochbl. Papierfabr.* **59,** 655–9; *Papier-Fabr.* **26,** 413–7(1928).—An address. Authorities differ as to the possibility of a wood famine. As a matter of fact, accurate estimates of the available wood supply and annual consumption of the world are practically impossible. For Germany, the matter is one of careful utilization and increased reproduction. R. H. Doughty

The chemical decomposition of wood. Bror Holmberg. Techn. Hochschule, Stockholm. *Papier-Fabr.* **26,** 506–8(1928).—See *C. A.* **22,** 3293. R. H. Doughty

The manufacture of groundwood pulp. C. O. Bachman. *Paper Mill* **51,** No. 34, 20(1928).—Investigation into the reason why groundwood prepd. from the same wood under apparently the same conditions and having the same freeness test exhibits wide variations in Mullen and Elmendorf test values has shown that the formation and structure of the individual fibers have a direct bearing on the strength of the finished paper, particularly when made on high-speed machines. Microscopical examn. of groundwood paper having a high Mullen test showed the fibers to be curved and barbed, while in low-strength papers the fibers are smooth and straight. A. P.-C.

The digestion of wood with cooking acids of low sulfite content. VIII. Erik Hägglund. *Papierfabr.* **25,** Fest- und Ausland Heft 60–3(1927); cf. *C. A.* **22,** 684.—Cooking acids of low sulfite content are often used to speed up the digestion process. The acidity during the course of the digestion process is smaller with a large sulfite content than with a cooking liquor with a small sulfite content. In the first stage of the cooking there is very little difference between the 2 types of liquors because any changes in the H-ion concn. have no effect on the sulfite addn. and there are present no large quantities of lignosulfonic or sulfuric acids. During the later period of the digestion process acidity plays an important role: reducing sugars appear and the yield of pulp is markedly affected. With acid liquors of low sulfite content the pulps resulting therefrom are inferior in tearing length and folding endurance. The fiber has become brittle. J. L. Parsons

The pulping of pine wood by the sulfite process. II. Erik Hägglund. Institute for Wood Chemistry, Åbo, Finland. *Cellulosechemie* **9,** 38–43(1928).—In continuation of previous work (*C. A.* **21,** 1710), H. studied the conversion of benzene-ether-acetone-extd. pine wood by the sulfite process and found a great similarity to results obtained with spruce wood. Ether- or benzene- extd. wood cannot be cooked to pulp by the usual sulfite process because such wood still contains MeAc and alc.-sol. substances which prevent conversion. Unextd. pine wood can be cooked to pulp with excellent yields by the use of highly concd. $NaHSO_3$ solns. The pulp, however, still contains considerable resin and cannot be used for paper manuf. without deresinification. The Keebra process as described in patent literature gives poor results with pine wood. Pretreatment of spruce wood with a lime or NaOH soln. at 105° causes a change in the wood and a liberation of HCO_2H and AcOH. A satd. lime soln. causes 1% of the wt. of the wood to be liberated as AcOH. The treatment has no effect on the sulfite cook which follows. The pulps have higher ash contents but the lignin is normal. Pine heartwood extd. with benzene-acetone, then with lime, is not converted as well as without a pretreatment. When extd. with only benzene and followed with a pretreatment with lime the results were even poorer. A pretreatment with HCl is of no advantage. The pretreatment of unextd. pine wood with alkalies at 105° gave unfavorable results. The residues contained considerable lignin and could not be defibrinated. The ash content was exceedingly high. L. C. Fleck

Wood and pulp mucilage. Carl G. Schwalbe. *Papierfabr.* **25,** Tech.-Wiss. Teil, 481–5(1927).—Mucilage formation from mech. pulp depends not only on the compn. of the wood, but also on the grinder pressure, the sharpness of the stone, the density of the pulp, the temp., etc. Hemicelluloses, pectins and substances closely allied to sugars and cellulose are the best mucilage-formers in wood. Freshly cut wood can be converted into mucilage more easily than stored wood. Lignin is not a good mucilage-former. Mitscherlich pulps are superior to Ritter-Kellner pulps in the manuf. of mucilage. Its formation is facilitated by bacterial action, overcooking, overbleaching and by the addn. of certain chemicals to the beater, such as $LiCl_2$ and $Ca(SCN)_2$. The soly. of cellulose mucilage in 16% NaOH soln., its pptn. from this soln. and the detn. of the height level in a tube after centrifuging indicate the degree of

beating of the stock. The most important property of pulp mucilage for paper manufacturers is its ability to weld the fibers together while moist. This is favored by pressure and careful drying, the latter being done on both sides of the sheet at the same time to avoid a loosening of the felting of the fibers. J. L. PARSONS

Determination of wood gum in pulps. HERMANN BUBECK. *Papierfabr.* **25**, Tech.-Wiss. Teil, 617–20(1927).—An improved procedure for the detn. of the wood gum in sulfite pulps is given which yields results in 2–3 hrs. instead of 2–3 days required by former methods. Five g. finely disintegrated pulp in a wide-mouth bottle are treated with 100 cc. of 5 vol.-% NaOH at 18° for 1–2 hrs. The mixt. is shaken once. At the end of the extn. time the mixt. is filtered, 25 cc. of the filtrate pipetted off and oxidized with an excess of 1.5 *N* CrO_3 soln. contg. H_2SO_4. The soln. is dild. to 250 cc. and the excess of CrO_3 detd. in 50 cc. iodometrically. One cc. 1.5 *N* CrO_3 soln. equals 10.13 g. wood gum. The degree of disintegration of the pulp and the temp. of the reaction are important factors in this test. J. L. PARSONS

Determination of mechanical wood pulp in paper by the phloroglucinol method. KORN. *Zellstoff u. Papier* **7**, 315–9(1927).—Absorption of phloroglucinol reagent by groundwood fibers in paper is not const but there is little error at the end of 24 hrs. Factors for calcg. results are given as 6.48 for mech. pulps and 1.21 for sulfite pulps, while Krull and Mandelkow found 7.84 and 1.34 for similar pulps. The purity of the reagent appears to play a role in the detn. of these factors. The calcd. results are supposed to be very accurate and between the limits of 40 and 70% groundwood in paper the chem. procedure is more desirable than the microscopical estn. J. L. PARSONS

The fluorescence of wood pulps and vegetable tannin extracts. O. GERNGROSS, N. BÁN, G. SÁNDOR AND K. TSOU. *Papierfabr.* **25**, Tech.-Wiss. Teil 49–52(1927).—An exptl. lecture demonstrating the effect of ultra-violet light on wood pulps and tannin exts., both natural and synthetic. Waste sulfite prepns. for tanning fluoresce violet in ultra-violet light. Cellulose, viscose rayon, hydrocellulose, starch, etc, yield a violet fluorescence after immersion in spruce bark ext ; nitrocellulose behaves negatively. Quebracho wood ext. produces a yellow fluorescence on various kinds of cellulosic materials, and nitro- and acetylcellulose. The yellow color becomes less pronounced with the increase in N content of the nitro derivative. Disaccharides, such as lactose and sucrose, as well as decompn. products of proteins, do not absorb the violet or yellow fluorescent substances. Evidence is given that the fluorescent property is probably not due to sulfonic acids. Filter paper dipped into spruce bark ext. fluoresces similarly to unbleached sulfite pulp. The fluorescent compd. is slightly sol. in hot water, resists org. solvents, is sensitive to alkalies and chlorine, but is not attacked by acids. J. L. PARSONS

Testing wood pulp for strength. J. L. A. MACDONALD AND G. A. CRAMOND. *World's Paper Trade Rev.* **89**, 1620–30(1928); *Paper Maker & Brit. Paper Trade J.* **75**, 617–21(1928); *Paper Mill* **51**, No. 28, 20 4, 36(1928); *Paper Trade J.* **87**, No. 5, 51–3(1928).—A discussion of the necessity of devising and standardizing a suitable strength test for pulps and of the conditions which should be met by any proposed method. The crucial point of any such method lies in the prepn. of suitable uniform test sheets which can be duplicated not only by the same experimenter in the same lab., but by different experimenters in different labs. Using an electrically driven disintegrating propeller and suitable pulp container, an electrically driven pebble mill, a modified Wilen sheet-making machine, a hand-operated "ledger" press for couching, a hydraulic high-pressure press, an electrically heated drying cylinder and a conditioning chamber, the authors have been able to prep. sheets sufficiently uniform to give satisfactory results with the Mullen bursting strength test, for either unbeaten or beaten pulp. A. PAPINEAU-COUTURE

Testing the bleaching quality of wood pulp. H. L. JOACHIM. *Zellstoff u. Papier* **7**, 361–2(1927).—A permanganate method for testing the bleach requirement of pulps is described which yields results in 20 min. Ten g. air-dry pulp is suspended in a l. of water by stirring and the temp. adjusted in a water bath to 37°, 25 cc. dil H_2SO_4 (1:4) are added and the mass is stirred with an automatic stirrer. Twenty-five cc. 1 *N* $KMnO_4$ are run in through the lid of the container while the stirrer is in motion. After exactly 7 min. $H_2C_2O_4$ is run into the jar from a buret and the excess $KMnO_4$ destroyed. The acid should be added 0.5 cc. every 30 sec. until the end point is approached. The relationship between the result obtained from the titration and the amt. of bleach required for a pulp will depend upon mill practice and the type of pulp produced. Comparative tests are given with the $KMnO_4$ method of Johnsen and Parsons and the Cl method of Roe. J. L. PARSONS

Bleach studies on wood pulps. IV. The influence of metals and metallic salts on hypochlorites and the bleaching process. HERMANN WENZL. *Papierfabr.* 25, Fest- und Ausland Heft 76–85(1927).—A large no. of metals effect a catalytic decompn. of hypochlorites into chlorides and O. The activity of metals differs widely: Al, Pb, Zn and Fe are not as effective as Mn, Co and Ni. The reaction velocity decreases with increase in hypochlorite concn. and becomes const. Velocity is also retarded by increasing the OH ion, and is accelerated by elevating the temp. The rate of reaction must be adjusted so as to produce a uniform bleaching action without destroying the fiber. In industrial operation the catalyzer may be suspended as the metal or added in the form of a salt in the bleach mixt. Analyses of pulps bleached in this way showed lower Cu nos. and higher α-cellulose values than pulps bleached in the usual way.

J. L. PARSONS

The digestion of beech wood with nitric acid. HERMANN SUIDA AND HANS SADLER. Institut für chem. Technologie organischer Stoffe an der technischen Hochschule Wien. *Papierfabr.* 25, Fest- und Ausland Heft 93–7(1927).—A brief review is given of pulp-producing processes utilizing HNO_3. Superior penetration of beech wood is obtained by cutting the material into longitudinal strips 1–2 mm. thick, and then immersing them in HNO_3 of the correct concn. at ordinary temp. for 2–3 hrs. The acid is then poured off, the chips are put in a digester and kept at 79° in a water bath for an hour. The chips do not lose their structure until, after washing, they are treated with a hot 2% soln. of NaOH. A 15% HNO_3 soln. was found to give the best results. Its consumption during the cooking process amounted to about 30% of the wt. of the wood. The pulp yield was about 40% and the α-cellulose content of the product was 85% and its Cu no. varied from 2.3 to 3.1. A pulp of higher quality can be prepared by a treatment with 9% NaOH soln.

J. L. PARSONS

Chemistry of beech wood; acetylation of beech wood and cleavage of the acetyl-beech wood. HERMANN SUIDA AND HUBERT TITSCH. Techn. Hochschule Wien. *Ber.* **61B**, 1599–1604(1928).—To obtain light on the state of the chief constituents of wood in their natural union, the free active groups in the wood should be protected and fixed by substituents in such a way that the union between the chief constituents themselves is in no way affected, and when these constituents are subsequently sepd. from each other the operation should be such that the protected active groups are not altered. S. and T. began work along these lines some time ago and now publish the results so far obtained because of the appearance of Fuchs' paper (*C. A.* **22**, 2744). Preliminary expts. showed that acetylation of the material used (red beech wood) with Ac_2O yields a product which, although lighter in color than the wood, otherwise has the same appearance as the latter and yields up no appreciable quantity of matter to the usual solvents. Most of the weaker catalysts (HNO_2, $ZnCl_2$, $Cu(OAc)_2$) are without influence up to a certain temp. range. Dil. H_2SO_4 behaves similarly while higher concns. produce an unmistakable hydrolysis of the wood. Acetylating mixts. which suffice to acetylate free cellulose do not acetylate wood more than does Ac_2O at a higher temp., but at the same time they produce Me_2CO-sol. products. These Me_2CO-sol. parts contain cellulose and incrustation substance in approx. the same proportion as that in which they are present in wood itself, *i. e.*, perhaps after wood has thus been made sol. there is still a certain union between the wood constituents. S. and T.'s expts. indicate that only acetylation with Ac_2O, with or without C_5H_5N, gives reliable results; under such conditions there is no hydrolysis of the wood. To remove the hemicelluloses as completely as possible the deresinated wood flour was freed of gum by the Friedrich and Diwald method; that the greater part of the furfural-yielding substances remains in the wood was confirmed. The wood flour was then boiled with Ac_2O. The max. acetylation was attained in 14 hrs.; the wood then contained about 32% AcOH (37% if C_5H_5N was used). Even without C_5H_5N the aniline sulfate reaction disappears completely, while phloroglucinol-HCl still gives a very faint pink color which also disappears after a reacetylation with C_5H_5N, when the AcOH content increases to about 35%. Sepn. of the wood constituents without splitting off the AcO groups proved difficult. To be sure, these groups are not held as loosely as had at first been feared. They are not split off by H_2O and even after several hrs. boiling with 2.5% H_2SO_4, the acetylated wood loses only about 4% AcOH. Towards alkalies they are more sensitive and they are split off by Friedrich and Diwald's method of hydrolysis with alc. HCl. Hydrolysis with AcOH contg. 0.25% HCl proved satisfactory, although some AcOH is split off. After 2 hrs. boiling H_2O pptd. 18.9% acetyl lignin and the residue (still contg. lignin) amounted to 55.5% of the total wt. The lignin part contained 28.9% AcOH and 14.10% MeO, the cellulose part 25.8% AcOH, 1.38% MeO and 20.6% xylan. On the basis of AcO-free lignin, the MeO content is 19.84%,

which corresponds to a primary lignin. Some side reactions also occur in such a hydrolysis; about 1/3 of the MeO in the acetylwood (originally 5.11%) is lost, presumably with the lignin in the H_2O-sol. portion. The acetyllignin so obtained is light yellow, not as white as that obtained by the alc. HCl method. The cellulose isolated from the same acetylated wood by the Cross and Bevan method contained 15.8% xylan and 29.1% AcOH. C. A. R.

Methylation of beech wood and cleavage of the methylbeech wood. ANTON VON WACEK. Techn. Hochschule Wien. *Ber.* **61B**, 1604-9(1928); cf. preceding abstr.—Methylation of the wood flour described in the preceding abstr. gave a product considerably lighter than the original material but otherwise entirely similar to it. After 5-7 methylations a max. MeO content of 39-39.4% was attained. The product does not change in solvents of methylcellulose and lignin, does not swell and hardly dissolves even in traces. If, after cold hydrolysis with 17% HCl according to Friedrich, it is refluxed with alc., 70-7% dissolves and the residue forms a swollen gelatinous mass From the alc. H_2O reppts. about 28%, the rest partly remaining in soln. and partly sepg. on heating in white flocks which redissolve on cooling. The part pptd. by H_2O contains 36-8% MeO, which is considerably higher than the value for an exhaustively methylated isolated lignin, so that apparently some cellulose ether is also pptd. The part flocculating out on heating dries to a white powder with 42.7-43% MeO (calcd. for trimethylcellulose 45.6%). If the hydrolyzed product is refluxed with Me_2CO instead of EtOH, there remains 64-6% of a very light, not at all swollen residue, 28% of which dissolves on 5-fold extn. with ice-cold H_2O (a 2nd hydrolysis of the H_2O-insol. part gives a product again partly sol. in H_2O); the substance flocculating out on heating the H_2O soln. contains 40.3-41.5% MeO after the 1st hydrolysis, 40.65% after the 2nd hydrolysis, and the H_2O-insol. part (after the 1st hydrolysis) dissolves to the extent of 33% in $CHCl_3$, the $CHCl_3$-sol. product contg. 40.71% MeO. From the original Me_2CO soln. H_2O ppts. a product with 26.48% MeO The above MeO values of 40.3-43.2% MeO correspond to trimethylcellulose mixed with 41-18.8% of dimethylcellulose. Since this trimethylcellulose does not dissolve before hydrolysis it may be concluded that this part, at least, of the cellulose is not combined through its three HO groups in the wood C. A. R.

The digestion of plant materials with dilute nitric acid. P. KRAIS, K. BILTZ AND O. RENNER. Deutschen Forschungsinst. fur Textilind. in Dresden. *Papierfabr.* **25**, Fest- und Ausland Heft 43-4(1927).—From 400-900 kg. straw, reeds and similar material have been successfully digested using dil. HNO_3 but the consumption of chem. was somewhat larger than with lab expts. The Cu nos of the pulps were not higher than 2.7 and the α-cellulose content (Jentgen method) varied from 79 to 86 for bleached pulps, which figures are comparable with sulfite pulp. Small amts. of HCN are produced in the process, accompanied by N oxides. J. L. PARSONS

The measurement of the viscosity of groundwood with the Schopper-Riegler apparatus. WALTER BRECHT AND ERICH SCHAUN. *Papierfabr.* **25**, Fest- und Ausland Heft, 45-60(1927).—The most favorable conditions for the operation of the Schopper-Riegler app. in detg. the viscosity of groundwood were investigated. For this purpose a graph is shown in order that all values may be referred to 20°. Sources of errors and their limits are tabulated. A stock density of 0.3% in 1000 cc. of suspension is recommended, with a temp. of 20°. The prepn. of this suspension is facilitated by the prepn. of a standard cake of fibers under certain conditions of pressure, namely 445 g. per sq. cm. The calcd. amt. of this cake to give 3 g. is then used for the suspension. A comparison is drawn with the Canadian standard freeness tester. J. L. PARSONS

Nitration of wood pulp by the Planchon process. G. PAYRAS. *Rev. gén. mat. plastiques* **4**, 515, 517(1928).—A brief description of the process, which consists essentially in immersing the pulp in sheet form in a bath of suitable compn. to obtain the desired degree of nitration. The temp. is kept const. (at or below 15°), and the time required is inversely as the temp. A. PAPINEAU-COUTURE

Pulping flax straw. EARL R. SCHAFER AND CLIFFORD E. PETERSON. Forest Products Lab., Madison, Wis. *Paper Mill* **51**, No. 41, 2, 10-8, 35(1928); cf. *C. A.* **21**, 1351; **22**, 1681.—Results are given in detail of the pulping of flax straw by the Cl process on a semi-commercial scale. The objective of producing pulps suitable for the better grades of paper was not entirely achieved. The pulps produced by the Cl process are very easily hydrated and consequently cannot be refined after the Cl treatment. The mech. processing must be done after the alk. digestion and prior to chlorination. Such mech. treatment is accomplished quite efficiently in a rod mill at moderately high consistencies. Steel rods or a steel lining in the mill cannot be used because

of the resulting contamination of the pulp with Fe. The phys. properties of the Cl flax pulps are largely dependent on the degree of pulping accomplished in the alk. digestion. The more raw pulps require proportionately a greater amount of Cl and the resulting waterleaf papers are, in general, proportionately more hydrated. While the variations in quality that can be attributed to the kinds of chemicals used in the predigestion are of less importance than the degree of pulping accomplished, certain advantages in the use of the sulfate process over the soda process have been noted. The chlorinated pulp that has been produced by a predigestion with Na_2SO_3 is slightly brighter in color and higher in strength than the "sulfate," but is more hydrated. The strength of Cl flax papers is generally higher when prepd. from the pulps requiring higher amts. of Cl, presumably because of the higher degree of hydration. The degree of whiteness of the paper, on the other hand, is higher with pulps that require the lower amts. of Cl. The color of Cl pulp prepd. from the entire flax straw is at best a grayish white. The addn. of small amts. of soda wood pulp to the Cl flax pulp furnish increases the opacity, reduces the hardness, and slightly reduces the strength of the waterleaf paper. None of the papers produced was in itself of commercial quality. The improvement in technic that would be possible in a commercial operation would undoubtedly eliminate many of the defects. Several of the exptl. papers indicate the possibility of incorporation of Cl flax pulps in the furnish of high-grade papers.

A. PAPINEAU-COUTURE

The problem of the technical utilization of chlorine for the decomposition of plant fibers. P. WAENTIG. *Papierfabr.* **25**, Tech.-Wiss. Teil, 144-8(1927).—A reply to a criticism by Wenzl in which calorimetric measurements of the chlorination process and the practical significance of these data are doubted. Direct measurements of the heat evolved during treatment with gaseous Cl are difficult because of the formation of HCl, which at high concns affects the reaction. There is no fundamental difference between the use of Cl gas and Cl water in the decompn. of plant fibers: in both cases a certain amt. of water must be present in the fibers in order that the reaction may proceed at all. The yields and nature of the cellulose obtained are similar. The possibility of the decompn. of wood into its fibers by Cl depends on the degree of division of the raw material. **Reply.** H. WENZL. *Ibid* 148-9.—The statements of Waentig are contradicted on the basis of actual experience. J. L. PARSONS

The technical use of chlorine in the decomposition of plant fibers. P. WAENTIG. H. WENZL. *Papierfabr.* **25**, Tech.-Wiss. Teil 340-2(1927).—A polemic discussion.

J. L. PARSONS

Fluorescence of pine bark, pine wood, sulfite pulp and liquor. O. GERNGROSS. *Z. angew. Chem.* **41**, 50-1(1928); cf. Gerngross, Bán and Sándor, *C. A.* **20**, 517; **23**, 839(1926); Gerngross, *et al.*, *Ibid* **1927**, 137.—A reply to the criticisms of Hägglund and Johnson (*C. A.* **22**, 1679). Pine wood on heating for a short time with dilute HCl yields a soln. with a weak reddish fluorescence in ultra-violet light, while cotton wool dipped in this soln. acquires a strong violet fluorescence similar to that shown by the aq. ext. of pine wood obtained by boiling under pressure. These observations are not in accordance with the view of Hägglund and Johnson that the fluorescence of sulfite pulp is due to the presence of lignosulfonic acid. B. C. A.

Fluorescence of sulfite pulp. E. HÄGGLUND AND T. JOHNSON. *Z. angew. Chem.* **41**, 51(1928).—A brief reply to G. (cf. preceding abstr.). B. C. A.

Constituents of the fiber of Japanese hemp-palm and sponge-gourd. S. MASUDA. *Cellulose Ind., Tokyo* **3**, 321-3(1927).—The fibers, which are very resistant to decay in water, were purified mech., cut up and analyzed. The results (calcd. on dry material) for hemp-palm (*Trachycarpus excelsus*, Wendl), and sponge-gourd (*Luffa cylindrica*, L., Roem), resp., are: water, 11.34% (12.65%); benzene ext. 0.77% (0.44%); alc. ext. 1.39% (2.9%); cellulose (on the extd., dry substance) 42.6% (57.65%); reducible sugar, after hydrolysis of the isolated cellulose, 92.3% (99.7%) of the theoretical yield; lignin 37.5% (14%) with 0.54% (0.18%) of ash; and pentosan 16.8% (18.6%). Mucic acid was not isolated and only a trace of mannose hydrazone was obtained from hemp-palm fibers, while those from sponge-gourd contained mannan 0.4%, galactan 1.8%. In both products, after hydrolysis with 3% H_2SO_4, xylose was identified.

The storage of beaten stock. W. SCHMID. *Papierfabr.* **25**, Tech.-Wiss. Teil, 20-2 (1927).—Neutral, hygroscopic substances may be added to paper stock in a kollergang to prevent the disintegrated material from becoming hard on storage. J. L. P.

Is the usual formula for calculating the thickness of plates in cylindrical covers to containers subjected to interior pressure correct? F. VON ZEIPEL. *Svensk Pappers-Tid.* **31**, 441-2 (1928); cf. *C. A.* **20**, 3813.—A preliminary study of formulas derived

from the general formula $s \quad p.D/2k$ to show that certain revisions are necessary.
W. SEGERBLOM

Is the formula for the strength of dome-shaped ends of containers designed for interior pressure correct? F. VON ZEIPEL. *Svensk Pappers-Tid.* **31,** 576–7(1928); cf. preceding abstract and *C. A.* **22,** 1849.—Explosions of steam boilers have made necessary multiplying the safety factor of the strength formula by the coefficient ψ, which varies with the radius of curvature. The Godesberg curve is given showing the relation of ψ to ends of varying curvature. W. SEGERBLOM

Pulp and paper work at Madison. C. P. WINSLOW AND C. C. HERITAGE. Forest Products Lab., Madison, Wis. *Paper Mill* **51,** No. 41, 9, 43–4(1928).—An outline of the work the pulp and paper division of the lab. is carrying out in coöperation with the pulp and paper industry on problems related to that industry. A. P.-C.

Science and the paper industry. E. ARNOULD. *Industrie papetière* **7,** 201–13 (1928).—An address showing the empiricism which still prevails in the paper industry and the lack of a proper scientific understanding of practically all the stages of the conversion of pulp into finished paper. A. PAPINEAU-COUTURE

Measuring pulp and wood values. C. K. TEXTOR. Northwest Paper Co. *Paper Mill* **51,** No. 40, 5–6(1928).—A brief discussion of the importance of devising tests which will give a true and reliable indication of the pulp-making qualities of woods and of the paper-making qualities of pulps. A. PAPINEAU-COUTURE

Technical control for board mills. E. FRANK WHITTINGTON. Sutherland Paper Co. *Paper Mill* **51,** No. 39, 28, 36(1928).—A discussion of the control required in board mills, suggesting the following: analysis of incoming raw materials (water, pulp and shavings, size, alum and fillers), weighing of beater furnish, check of size and alum solns., detn. of the p_H, freeness and consistency of the beater furnish, detn. of the basis wt., caliper, H_2O content, degree of sizing, surface finish or gloss, ash content and bursting, tensile and folding strengths of the finished board. A. PAPINEAU-COUTURE

Control of losses in (pulp and paper) manufacturing processes. WALTER BRECHT. *Papier-Fabr.* **26,** 469–73(1928).—General. Raw materials, finished products and wastes of all processes should be systematically checked. The use of controlling and recording instruments, some of which are described, is recommended. Losses not only of material, but of time, steam, power, etc., should be considered. R. H. D.

Technical men and the new competition (in the paper industry). D. C. EVEREST. *Paper Trade J.* **87,** No. 15, 38–44(1928).—An address. The present conditions of keen competition and excess productive capacity over consumption existing in the paper industry are attributed to the progress which has taken place in manufg. processes through the efforts of technical men. The remedies suggested are either legislation to regulate production according to demand or development of new uses for the finished products so as to increase consumption, with possibly best results being obtained by a combination of the two. A. PAPINEAU-COUTURE

Refractories (in the pulp and paper industry). REGINALD TRAUTSCHOLD. *Paper Trade J.* **87,** No. 14, 44–8(1928).—A brief discussion of the functions and advantages of air-cooled furnace walls and of refractory applications in pulping (lining digesters, acid towers and lime kilns). A. PAPINEAU-COUTURE

United States patents on paper making. CLARENCE J. WEST. National Research Council, Washington. *Paper Trade J.* **87,** No. 5, 58–9(1928); cf. *C. A.* **22,** 3296.—A list of U. S. pats. on paper making issued in April, May and June, 1928.
A. PAPINEAU-COUTURE

The foaming of paper stock. H. ROSCHIER. *Pappers och Travarutidskrift for Finland,* No. 20(1926); *Papierfabr.* **25,** Tech.-Wiss. Teil 211–3(1927).—The theory of foam formation is discussed. A pure Na abietate soln., to which $Al_2(SO_4)_3$ has been added, does not yield foam at p_H 4.6–5.8. The abietic acid at this p_H is in the form of the Al salt, which is difficultly sol. in water. $Al_2(SO_4)_3$ does not influence the surface tension of water. Com. rosin always yields a foam over the above p_H range, increasing with increase in H-ion concn. The foaming is least at p_H 4.5–5.5 when glue or gelatin (even as low as 0.09%) is added as a protective colloid. Sources of foam in paper stock are: fillers, sizing agents, improperly washed pulp contg. bleach residues, unbleached pulp contg. traces of waste sulfite liquor, $Al_2(SO_4)_3$ after hydrolysis, etc. Often the addn. of another colloidal substance to a foaming soln. decreases the amt. of foam by displacement from the surface of the soln. J. L. PARSONS

Paper from cornstalks. E. F. HULBERT. Cornstalk Products Co. *Paper Trade J.* **87,** No. 13, 51–4(1928); *Paper Mill* **51,** No. 39, 12, 38(1928).—An outline of the work done by the Euromerican Cellulose Products Corp. and the Cornstalk Products Co. on the production of paper pulp and of high α cellulose for rayon manuf. from corn-

stalks, with a description of the process used and of the 25-ton mill at Danville, Ill. (1) Cornstalk waste can be successfully gathered and delivered to the pulp mill at a price that makes its commercial use as a possible substitute for wood pulps an attractive venture. (2) A clean, high-bleached white pulp suitable for the production of many grades of white papers can be produced in 35–45% yield (on the dry wt. of the stalk) at a price below that of chem. wood pulp. (3) The character of the pulp produced can be more or less controlled by proper control of the raw material in growing and gathering. (4) The pulp reacts very quickly to certain handling in the process and complete hydration can be accomplished almost instantaneously and almost as quickly it can be dehydrated and a free soft pulp obtained. (5) Almost any quality found in wood-pulp papers can be reproduced with 100% corn pulp. (6) Newsprint equal in strength and quality to that at present made can be produced from 10% sulfite and 90% corn. (7) Corn board takes coloring and finishing the same as wood-pulp board and has a good bending test; corrugating sheet made from corn has much greater strength than that made from straw and has a very high compressive strength. (8) Completely refined pulp can be made without the use of beaters, and completely hydrated pulp can be made without the use of beaters or chemicals. A. P.-C.

The paper-making qualities of woods and plants from Indo-China. F. Heim de Balsac and A. Deforge. Station Biol. d'Auteuil-Boulogne. *Chimie et industrie* **Special No.,** 592–5(April, 1928).—The pulp yields and fiber measurements of 56 Indo-Chinese trees and plants (designated by both their native and botanical names) are tabulated. The results show that a no. of these fibers would be suitable for paper making. A. Papineau-Couture

Degree of sizing and finish. H. Schwalbe. *Papierfabr.* **25,** Tech.-Wiss. Teil, 173–6(1927).—A short review is given of recent methods for detg. the sizing of paper. The app. of Albrecht is described. The methods of Albrecht and Klemm do not yield comparable results. As a rule the degree of sizing is reduced with increase in finish due to calendering. J. L. Parsons

Advance in sizing paper and pulp (with wax). E. Belani. *Papier-Fabr.* **26,** Amt. und Wirtschaft. Teil, 485–7(1928).—The advantages of wax sizing are enumerated, and practical suggestions for the application of the trade-named product "*Prestokoll.*" are given. R. H. Doughty

The rosin sizing of paper. I. Historical review. S. R. Olsen. Univ. of Minn. *Paper Trade J.* **87,** No. 15, 59–63(1928).—A review, bringing out the lack of fundamental research. In connection with the apparent contradictions in the results obtained and theories propounded by different investigators, no mention is made of Roschier's work (*C. A.* **22,** 1851, 3299), possibly because the article was prepd. before this work had been published. A. Papineau-Couture

Surface sizing. H. Postl. *Papierfabr.* **25,** Tech.-Wiss. Teil, 115–7(1927).—A brief description of surface-sizing practice in the paper industry. J. L. Parsons

The dispersion of rosin for paper sizing. Pierre Delcroix. Papeteries Navarre. *Pulp Paper Mag. Can.* **26,** 1049–51(1928).—See *C. A.* **22,** 1853. A. P.-C.

Hard water and rosin-size emulsions. C. N. Ridley. *Paper Makers' Monthly J.* **66,** 415–9(1928).—A discussion of the effects of the permanent hardness of H_2O on the pptn. of rosin from size emulsions. Expts. are described showing that the amt. of rosin deposited from emulsions is not in direct proportion to the increase in hardness but increases more rapidly than the hardness because of the weakening of the stabilizing film of Na resinate through the action of the Ca and Mg salts in the water. The rate of sepn. of rosin from its emulsion increases more rapidly with water contg. permanent hardness alone than with water contg. both permanent and temporary hardness, which is explained by the fact that Na_2CO_3 set free by the action of the temporary hardness on the Na resinate reacts with the permanent hardness of the water and prevents it from affecting the resinate. A. Papineau-Couture

Control of stock losses in the paper mill. A. T. Gardner. Combined Locks Paper Co. *Paper Trade J.* **87,** No. 14, 61–2(1928); *Paper Mill* **51,** No. 40, 16, 36(1928).—A discussion of the importance of making a complete survey of the mill, so that all the small losses which make up the total loss can be detd., with general indications as to how to obtain best results in fiber recovery from white water and a description of a satisfactory reclaiming system in use in a book-paper mill. A. P.-C.

White-water re-use. L. M. Booth. *Paper Trade J.* **87,** No. 12, 55(1928).—A brief discussion showing that the white-water problem should be viewed as one of paper making rather than as one of waste recovery. A. Papineau-Couture

Manufacture of wadding from cellulose. J. A. Colin. *Mon. papeterie belge* **8,**

391–7(1928).—A detailed description of the raw materials used and of the equipment and process utilized for its manuf. A. PAPINEAU-COUTURE

Measuring the color of paper. JEAN COUTROT. *Mon. papeterie française* **59,** 135–9(1928).—A description of the T. C. B photo-colorimeter and of its application to the measurement of the color and gloss of paper. A. PAPINEAU-COUTURE

The yellowing of paper. M. MARINI. *Paper Trade J.* **87,** No. 5, 59–60(1928).—See *C. A.* **21,** 2188. A. PAPINEAU-COUTURE

Schur's freeness indicator and refining control. M. O. SCHUR. *Paper Trade J.* **87,** No. 2, 55–62(1928).—A description of U. S. pat. 1,653,125 (*C. A.* **22,** 868). A. PAPINEAU-COUTURE

Determination of opacity of paper. ANON. *Paper Trade J.* **87,** No. 10, 64(1928).—A detailed description of the official method of the Techn. Assoc. of the Pulp and Paper Industry. A. PAPINEAU-COUTURE

Measuring the bulk of paper. ANON. *Paper Trade J.* **87,** No. 8, 51(1928).—An outline is given of the investigation carried out at the U. S. Bur. of Standards with a view to developing a standard method for measuring the bulk of paper. Two proposed methods are described. A. PAPINEAU-COUTURE

Fastness measurements for colored papers. G. DALEN AND P. WILKE. *Paper Trade J.* **87,** No. 7, 58–60(1928).—From qual. tests with the quartz-mercury lamp it is concluded that it should furnish a satisfactory substitute for sunlight in making fading tests on papers. One hour of lamplight is equiv. to 3 hrs. of direct sunlight or to 10 days of north daylight, under the conditions used. Temp. and water content of the sample affect the results; activation of the air by the lamp apparently does not. Aging of the lamp is not a serious factor after it has been operated a few hrs. A. P.-C.

Further notes on freeness testing. D. S. DAVIS International Paper Co. *Pulp Paper Mag. Can.* **26,** 1055–7(1928); cf *C. A.* **21,** 1710.—An exptl. and mathematical comparison of the 3 types (so-called "50-50" model, 1925 model, 1927 model) of the Williams Model "B" freeness tester showed that the calibration of the 1927 tester is, like that of the earlier models, independent of the properties of any pulp. The readings obtained with the 1925 and 1927 instruments agree on water alone, but differ on pulp samples. The linear relationship between the reciprocal of the freeness and consistency of the stock holds with the 1927 as with the 1925 model. Conversion between the 3 freeness scales is possible by means of plots and equations which are given, and the effect of temp. on freeness is susceptible of fairly simple mathematical treatment, whatever the freeness scale. A. PAPINEAU-COUTURE

Detection of formaldehyde in paper. T. C. BENTZEN. Whiting-Plover Paper Co. *Paper Trade J.* **87,** No. 3, 49(1928); *Paper Mill* **51,** No. 30, 18(1928); cf. *C. A.* **21,** 2983.—As a preliminary test add a little resorcinol to 50 cc. of 27% NaOH soln., immerse about 1 g. of paper and boil 30 min. If no red color develops it is proof of the absence of CH_2O. If a red color develops the presence of CH_2O should be confirmed by distg. about 1 g. of finely ground paper in the presence of 50–100 cc. distd. H_2O and testing the distillate by one or more of the following methods: Nessler's reagent, resorcinol test, Ag mirror test, $PhNH_2$ test. A. PAPINEAU-COUTURE

Determination of gloss of paper. ANON. *Paper Trade J.* **87,** No. 11, 55(1928).—A detailed description of the official method of the Tech. Assoc. of the Pulp and Paper Industry. A. PAPINEAU-COUTURE

Investigations on the fluorescence of papers. M. FALLOT. *Chimie et industrie* **Special No.,** 596–8(April, 1928).—Examn. of various paper-making materials by means of ultra-violet light filtered through a Wood screen (which eliminates practically all light except that of λ = 3650 A. U.) led to the following conclusions: Of 10 varieties of wood from Southern France, 9 gave a more or less brownish violet fluorescence and 1 (acacia) a very bright yellow fluorescence. Of 70 pulps prepd. from about 40 different fibers, all those carefully prepd. in the lab. had a very slightly pinkish white fluorescence, commercial bleached pulps had a fairly light violet fluorescence, and unbleached and mech. pulps had a brown fluorescence, the depth of which varied with the purity of the pulp. Papers prepd. from spruce soda pulp had a brownish (Havana shade) fluorescence whether loaded with kaolin, talc, $CaSO_4$ or $BaSO_4$, or whether sized with rosin, starch or gelatin. Under similar conditions, papers prepd. from unbleached spruce sulfite all had a more or less bright violet fluorescence and those made from cotton a more or less pronounced pinkish fluorescence. As a rule fillers deepen the color of the fluorescence and sizing (especially with rosin) makes it lighter; but at times there is no appreciable difference. Dyes give the paper the fluorescence characteristic of the dye. Photographic films were wrapped in different papers which had been exposed for 15 min. to light of 3650 A. U. and were kept in the dark for 2 months, after which

they were developed. The results showed that all papers made from rags or from properly bleached pulps (whether produced in the lab. or commercially) were without effect; but the ones made from pulps contg. impurities caused some fogging, unbleached sulfite being somewhat less active than unbleached soda pulp. A com. so-called "hemp" pulp, which fogged the film, was found to contain hemp stalks, while others sold as "rag" were loaded with about 5% $CaCO_3$. The fogging action of newsprint is due chiefly to its groundwood content, and very seldom to the printing ink. As regards the action of fillers, the results indicate that $BaSO_4$ has the greatest effect, $CaSO_4$ has less, china clay still less, and talc none at all; but the behavior of these substances probably varies according to their origin and compn. On the whole, rosin size has a greater action than gelatin or starch. Red and black aniline dyes generally reduce the fluorescence; certain grades of lampblack have a distinct effect, possibly on account of the impurities which they contain; of a no. of dyes studied, acid and basic dyes (even the blacks) had a fairly strong fogging action, while direct dyes were much less active, Oxydiazol Black NJEE being without noticeable action. A. P.-C.

The development of vacuum (paper machine) dryers. W. Schmid. *Papier-Fabr.* **26,** 537-40(1928).—The development of the Minton dryer as shown by German patents is traced. Its advantages are, savings in heat, space and felt cost, and greatly decreased paper shrinkage. R. H. Doughty

The vacuum method of drying paper. Ogden Minton. *Paper Trade J.* **87,** No. 11, 57-62(1928).—A discussion of the merits and performance of the Minton vacuum dryer, based on the results obtained with the com. dryer installed at the Kenogami mill of Price Bros. in Dec. 1926, showing that the claims made by M. in 1922 (before such a dryer had been constructed and tried out on a com. scale) concerning the superiority of vacuum drying have now been proved in actual practice. A. P.-C.

The Fidalgo pulp-drying system. R. D. Kehoe. *Paper Trade J.* **86,** No. 26, 50-2(1928).—A discussion of the merits of the process and of improvements being worked out in the equipment used in carrying it out. Results of tests are given showing that the strength of pulp dried by this process is but very slightly lower than that of moist lap pulp. A. Papineau-Couture

Radio moisture tester (for paper-making machines). James d'A. Clark. *Pulp Paper Mag. Can.* **26,** 1124-6(1928).—A complete description of Eng. pat. 275,741 (*C. A.* **22,** 2331), covering a device for detg., indicating and controlling the moisture content and quality of paper on the paper-making machine. A. Papineau-Couture

Pre-drying of paper. Wm. P. Argy. *Paper Mill* **51,** No. 28, 12(1928).—It was found that by pre-heating the paper before putting it through the last press the steam required to dry the paper is considerably reduced, resulting in a lowered steam consumption for a given output or in greater output with the same steam input into the dryers. A. Papineau-Couture

An improved humidity chart (for paper-mill use). D. S. Davis. International Paper Co. *Pulp Paper Mag. Can.* **26,** 1158-60(1928).—A description of a humidity chart which is an improved form of a chart given by Walker, Lewis and McAdams in their "Principles of Chem. Engineering," McGraw-Hill (1927) (*C. A.* **22,** 649), and which has been found particularly suitable to paper-mill problems. It has a temp. range of 0–150° F., and a humidity range of 0-80 lb. H_2O vapor per 1000 lb. dry air. The method of using the chart is explained by means of an example.
A. Papineau-Couture

Paper coating. H. E. Hutton. *World's Paper Trade Rev.* **89,** 1788–94, 1878–82, 1938, 1940(1928); *Paper Mill* **51,** No. 25, 18–26(1928).—A description of the manuf. of coated papers, outlining the variations in treatment to which it is subjected according to its destination. A. Papineau-Couture

Dyeing paper with direct colors. Fred Grove-Palmer. *Paper Maker & Brit. Paper Trade J.* **76,** 21, 23(1928); *Pulp Paper Mag. Can.* **26,** 1127–9(1928).—A brief general description of the uses for which direct dyes are used for coloring paper and of the precautions to be taken. A. Papineau-Couture

Basic colors for dyeing paper. Fred Grove-Palmer. *Paper Trade J.* **87,** No. 5, 56–7(1928).—A brief description of the technic of the dyeing of paper with basic dyes.
A. Papineau-Couture

The manufacture of safety paper. I. Special paper structures. Joseph Rossman. *Paper Trade J.* **87,** No. 10, 61–4(1928).—Abstracts of U. S. pats. on the production of safety paper by the incorporation of the materials during the paper making. **II. Chemical surfacing of paper.** *Ibid* No. 12, 56–60.—Abstracts of U. S. pats. on methods of making safety paper in which the finished paper is treated superficially in some way

as by impregnation with chemicals which will be discolored by ink eradicators, or is subjected to special printing methods. A. PAPINEAU-COUTURE

Possibilities of the jordan. G. S. BRAZEAU. *Paper Ind.* **10**, 664–5(1928); *Paper Trade J.* **87**, No. 4, 53–4(1928).—A brief discussion of the possibility of eliminating beaters in the treatment of pulp by hydrating it exclusively in jordans, and of the factors which make an efficient jordan. A. PAPINEAU-COUTURE

Processes for deinking paper. JOSEPH ROSSMAN. *Paper Trade J.* **87**, No. 3, 50–5(1928).—Abstracts of U. S. and foreign pats. dating as far back as 1800. A. PAPINEAU-COUTURE

Technology of ink removal from paper. R. EDMUNDS. *Papierfabr.* **25**, Tech.-Wiss. Teil, 75–6(1927).—The Baskerville and Stevenson process for deinking paper is described. Better results are claimed by using 90 kg. anhyd. Na_2CO_3 per ton of old paper. The recovery of book paper is discussed. J. L. PARSONS

The world production of newsprint paper, with especial reference to the United States and Canada. W. SCHMID. *Papier-Fabr.* **26**, 475–81(1928).—World figures on production and consumption for 1926 are analyzed. The increase in production in North America in the period 1913–26 is discussed. R. H. DOUGHTY

"Lignocell" paper. VON POSSANNER. *Papierfabr.* **25**, Tech.-Wiss. Teil, 601–3(1927).—The "lignocell" process for mfg. pulp is a modification of the method for producing steamed mech. pulp. Advantages of "lignocell" compared to mech. pulp are (1) the stock is lighter colored, permitting lighter dyeings; (2) opacity is good, allowing the manuf. of thinner papers; (3) conversion to paper is easier; (4) fibers possess superior felting qualities; and (5) the fibers are practically acid-free, which is not the case with mech. pulp fibers. "Lignocell" paper has a good feel and crackle and possesses a tearing strength very close to that of paper made from chem. wood pulp. Five photomicrographs accompany the article. J. L. PARSONS

Influence of atmospheric moisture on the bursting strength of paper. CHARLOTTE BOERNER. Staatlichen Materialprüfungsamt, Berlin-Dahlem. *Papier-Fabr.* **26**, 521–2; *Wochbl. Papierfabr.* **59**, 910–11(1928).—Of 13 samples tested, all showed an increase in burst (Mullen) on decreasing the relative humidity from 90 to 65%. On decreasing it further to 40%, 8 samples showed higher strength than at 65%, 5 somewhat lower. R. H. DOUGHTY

Proper working of waste-recovery apparatus in paper mills. G. CESCONI. *Bol. staz. sper. carta e fibre veg.* **1928**, 64–6.—With Fe recovery vats, the joints of the plates, the heads of the nails and solderings all collect solid matter that is detached in time and may enter the paper. Hence, all vats should be of concrete. To insure the return of clean water to the paper machine, the surface touched by the H_2O must be smooth, visible and accessible, so as to facilitate cleaning. Fe pipes cause impurities, rust and deposits. Zinked pipes without joints avoid these. Froth must be avoided, and if formed should be eliminated. R. SANSONE

The "kerosene" test for roofing felt. P. W. CODWISE. Certainteed Products Co. *Paper Trade J.* **87**, No. 12, 60(1928); cf. *C. A.* **22**, 1837.—The test consists essentially in satg. the sample of dry felt with a measured vol. of kerosene, which is considered to be a suitable liquid saturant, to det. the amt. of voids in the sample so as to calc. therefrom the theoretically possible % of asphalt satn. The technic of the test is described in detail. A. PAPINEAU-COUTURE

The strength of grinding stones. GOSTA M. JOHANSSON. *Svensk Pappers-Tid.* **31**, 469–72(1928).—By means of mathematical considerations J. concludes that pulling strain is the only essential danger to grinding stones. Flying apart of stones can be best prevented by reducing the peripheral speed and the pressure on the surface. J. recommends investigation (*a*) in a chem. lab. of the chem. and phys. compn. of grinding stones when fresh, and after 1 and 2 years' aging, and (*b*) in a mech. lab. of the strength against pressure and strain when fresh and after 1 and 2 years, aging. W. S.

Effect of sulfite waste liquor on the acidity of river water (ÖMAN) **14.** **The percentage formula of pentosans** (SCHORSCH) **10.** **Rotary furnaces for pyrites burning** (DEBUCH) **18.** **Explosion risk in the industrial preparation of absolute alcohol from sulfite spirit** (SCHLUMBERGER) **16.** **New developments with dispersed rubber** (WINKELMANN) **30.** **Drying cylinder for paper, etc.** (Austrian pat.) 109,048) **1.** **Softening and waterproofing cellulose products** (Fr. pat. 635,637) **18.** **Determining and controlling the humidity of paper and cellulose** (Fr. pat. 635,296) **1.** **Photographic films** (Fr. pat. 635,281) **5.** **Use of jets of liquid such as water for detaching cellulosic bodies from their molds** (U. S. pat. 1,687,282) **13.** **Apparatus for drying paper in long lengths** (Brit. pat. 285,378) **1.**

MADDOX, H. A.: **Paper: its history, sources and manufacture.** 2nd edition. London: Sir Isaac Pitman and Sons, Ltd. 3s. Reviewed in *Paper Making* **47**, 169 (1928).

Cellulose. O. C. STRECKER. Brit. 284,846, Jan. 13, 1927. Practically pure cellulose, in high yield, is obtained from materials such as red pine wood, beech wood, bamboo, straw and Scotch fir or other resinous woods by use of boiling solns. contg. hydroxy compds. of the isocyclic series in which at least 1 H atom of the OH group has been replaced by a metal preferably of the alkali, alk. earth or Mg group. Metal derivs. of phenol, cresol, naphthol and their hydrogenated derivs. as substitution products contg. halogens or NO_2 groups may be used and these substances are preferably used in the form of permanent emulsions which may be stabilized by addns. such as castor oil soaps, cyclohexanol and salts of humic acid. Penetration of the vegetable fibers is promoted by addn. of various salts such as Na_3PO_4 or various other substances and catalysts also may be used, of which BaO_2 is given as an example. The boiling may be effected under pressure to expedite the operation and attack on the cellulose fibers, themselves, may be checked by addn. of substances such as Na_2SO_3, Na formate, Na malate, Na phenylsulfonate or their homologs or substitution products, stannous oxide or the like. Metal compds. may be added during the process to replace the metal cation entering into the lye by chem. reaction with acids formed from the vegetable fibers. Numerous details and modifications are given.

Cellulose esters. I. G. FARBENIND. A.-G. Fr. 635,963, June 14, 1927. See Brit. 279,796 (*C. A.* **22**, 3044).

Cellulose esters. I. G. FARBENIND. A.-G. Brit. 284,298, Jan. 27, 1927. Insol. or but slightly sol. cellulose esters of the higher aliphatic acids such as cellulose tristearate, cellulose dipalmitate or cellulose trilaurate, prepd. by reaction between cellulose and an acid chloride in the presence of pyridine, quinoline or similar base, are rendered sol. in usual org. solvents and suitable for manuf. of soft and elastic films, by treating them in a liquid medium and at a high temp. (80–200° according to different examples) with an acid, an acid anhydride or a salt of a strong acid with a feeble base, *e. g.*, with trichloroacetic acid, pyridine hydrochloride, $FeCl_3$, $ZnCl_2$, $AlCl_3$ or benzenemonosulfonic acid. The esters are pptd. in flocculent form by pouring the solns. into MeOH, EtOH or acetone. The treatment is also applicable to cellulose mono-esters of higher aliphatic acids. Cf. *C. A.* **22**, 3988.

Cellulose acetates. HENRY DREYFUS. Can. 283,661, Oct. 2, 1928. Cellulose acetates are produced by preheating cellulosic material with a gas comprising vapors of AcOH and an inert gas such as air and then acetylating the preheated cellulose in the presence of condensing agents in quantity less than 5% on the wt. of the cellulosic material and in the presence of AcOH in quantity 6 times the wt. of the cellulosic material, the acetylation being effected in presence of org. products suitable for the prevention of gelatinization of the cellulose derivs. during acetylation.

Acylation of cellulose. HENRY DREYFUS. Can. 283,660, Oct. 2, 1928. Cellulosic material is treated with vapors of a lower fatty acid (*e. g.*, AcOH) and then air is passed through the material to remove at least a part of the acid.

Plastic composition containing acetylcellulose. GEORGES E. ZELGER (to DuPont-Pathe Film Mfg. Corp.). U. S. 1,685,443, Sept. 25. Acetylcellulose 100 is used with monoethyl diphenyl phosphate 20 parts. U. S. 1,685,444 specifies acetylcellulose together with monoethyl di(monochlorophenyl) phosphate or other suitable phosphoric esters contg. both aliphatic and halogenated aromatic radicals.

Coloring cellulose derivatives. I. G. FARBENIND. A.-G. Brit. 284,999, Feb. 7, 1927. Sol. or insol. inorg. or org. pigment dyes may be mixed with solns. such as those of ethylcellulose or acetylcellulose and these colored solns. then used for printing designs on or for coloring cellulosic films such as those formed of regenerated cellulose from viscose or ammoniacal Cu oxide solns. or films of nitrocellulose, ethylcellulose or the like. Metallic powders also may be used as coloring agents.

Films and other products from emulsified and dissolved cellulose derivatives. I. G. FARBENIND. A.-G. Brit. 285,355, Feb. 12, 1927. Elastic masses, films, coating compns. and other products are prepd. by desiccating emulsions contg. both cellulose derivs. insol. in water but sol. in org. solvents and those that are sol. in water or that swell in water. Suitable water-sol. derivs. are cellulose ethers contg. 1.5–2.5 methoxyl groups, or ethylcelluloses contg. not more than 1.5 ethoxyl groups, or water-sol. hydroxyalkyl cellulose ethers as obtained by the action of an alkylene oxide on cellulose or an alkylene chlorohydrin on soda cellulose. As water-insol. derivs. there may be used

nitrocelluloses, acetylcelluloses and other org. acid esters, and water-insol. cellulose ethers. Numerous details, modifications and examples are given.

Apparatus for making coagulated cellulose films. O. SINDL. Brit. 284,725, Feb. 5, 1927.

Esterifying mercerized cellulose with lower aliphatic acids. HANS T. CLARKE and CARL J. MALM (to Eastman Kodak Co.). U. S. 1,687,059, Oct. 9. Cellulose such as cotton, tissue paper, or bleached sulfite wood pulp is mercerized and then heated with HOAc or other aliphatic acid contg. 2 to 7 C atoms, without a catalyst, at a temp. of 100–170° until the acyl group in the ester thus produced reaches at least 8% (no other acylating agent being used). U. S. 1,687,060 specifies cellulose esters contg. an acyl group with a halogen-substituted chain (the halogen being more than 1% the wt. of the ester), which may be formed by brominating cellulose crotono-stearate or by other reactions and are suitable for making films, etc. Cf. *C. A.* **22**, 2273.

Washing artificial products obtained from cellulose solutions. HERMINGHAUS & CO. G.M.B.H. LEOPOLD HESSE and HERMANN RATHERT. Fr. 635,680, June 7, 1927. Bobbins or rollers of products from cellulose solns. are washed by very small drops of water obtained, *e. g.*, by the use of porous distributors. The water may be transmitted to bobbins below without formation of drops by wires covered with cloth.

"Painting-ground" for artists. C. F. CROSS, VISCOSE DEVELOPMENT CO., LTD., and WINSOR & NEWTON, LTD. Brit. 284,363, Aug. 26, 1926. Blotting paper may be affixed to a cellulose textile backing by means of viscose which completely fills the textile, and the material afterward sized with viscose; or, cellulose pulp may be incorporated with viscose and the mixt. applied to textile material.

Viscose. DU PONT RAYON COMPANY. Fr. 635,408. June 1, 1927. Diagonal protuberances or undulations are made on the surface of sheets of wood pulp used in viscose manuf. to give the caustic liquor, in the setting process, immediate free access to all parts thereof, and thus avoid the formation of brown spots caused by the presence of hemicellulose in already-used liquor. The presence of hemicellulose in the liquor up to 3.5% accelerates the subsequent ripening.

Viscose products. BORVISK SYNDICATE LIMITED. Fr. 636,090, June 17, 1927. A viscose contg. oils or fatty substances such as olive or castor oil or emulsified mineral oils is used for making threads, etc. A hydrogenated hydrocarbon such as tetralin may also be added.

Viscose silk and films. COURTAULDS LIMITED. Fr. 635,294, May 13, 1927. Viscose contg. 1 to 3% of a sol. carbonate is projected into a bath contg. 9 to 11% H_2SO_4, 10 to 14% Na_2SO_4, 8 to 14% $MgSO_4$ and 0 to 8% $ZnSO_4$, the bath contg. 25 to 28% of total sulfates.

Artificial textiles. NAAMLOOZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIEK. Fr. 635,195, May 30, 1927. Textiles having a dull appearance are made from viscose to which has been added during the manuf. a sulfide, sulfite, thiosulfate, polysulfide or other compd. liberating S. The product is treated in the usual way but the S is retained in the textiles.

Artificial silk. G. BONWITT. Brit. 285,066, Feb. 11, 1927. Threads with a "reduced luster" are obtained from viscose by emulsifying with the latter substances such as mono- and di-chlorobenzenes, xylene and hydrogenated naphthalenes or their mixts. which preferably have about the same sp. gr. as the viscose to be spun.

Artificial silk. WILLIAM P. DREAPER. Can. 283,659, Oct. 2, 1928. Artificial filaments and yarns in imitation of "gum type" silk are produced by treating the freshly pptd. gel filaments produced from viscose solns. before they are dried in a state of tension with a desulfurizing soln. to which there is added NaCl in amt. substantially 80% of the satn. value at atm. temp.

Artificial silk. JAMES M. LEAVER (to Pacific Lumber Co.). U. S. 1,685,640, Sept. 25. Soln. producing artificial silk is discharged downwardly in a plurality of streams which are permitted to fall through the air to reduce their diam. and the falling streams are brought into contact with a moving sheet of setting soln. having a surface speed approx. the same as that of the falling streams at their point of contact with the sheet. An app. is described.

Artificial silk. I. G. FARBENIND. A.-G. Fr. 635,774, June 10, 1927. The pptg. agents for artificial silk contain CO_2 or bicarbonates.

Filter for solutions used in manufacture of artificial silk. WM. P. DREAPER. U. S. 1,685,775, Oct. 2. Structural features.

Artificial threads. CHEMISCHE FABRIK VORM. SANDOZ. Fr. 635,304, May 21, 1927. Vegetable fibers are acetylated by a mixt. of Ac_2O, AcOH and a catalyst, the acetylation being pushed only to the mono- or diacetate, with catalysts formerly used

for making the triacetate. Examples are given in which H_2SO_4 and $ZnCl_2$ are used as catalysts.

Apparatus (with reciprocating troughs for freshly spun threads) for making artificial silk. HOLKENSEIDE GES (to J. P. Bemberg A.-G.). Brit. 284,618, Feb. 1, 1927.

Apparatus for spinning artificial silk. C. HAMEL A.-G. Brit. 284,986, Feb. 7, 1927.

Apparatus for spinning artificial silk. H. KINDERMANN. Brit. 285,587, Nov. 23, 1926. Structural features.

Centrifugal spinning box for spinning artificial silk. F. BEIER (to Bergmann Elektricitats-Werke A.-G.). Brit. 285,011, Feb. 8, 1927.

Tower construction for making bisulfite liquor. JACOB D. JENSSEN (to G. D. Jenssen Co.). U. S. 1,684,494, Sept. 18. A valve-system construction and other structural details are specified.

Regeneration of black liquor. ALFRED H. WHITE (to John E. Alexander and Edward G. Goodell, Trustees for Falls Mfg. Co., The Wausau Sulphate Fibre Co., The Nekoosa-Edward Paper Co. and Stevens Point Pulp and Paper Co.). Can. 283,820, Oct. 2, 1928. Black liquors from the sulfate pulp process are regenerated by concg., adding sufficient burned CaO to raise the temp. to distil destructively the org. constituents of the black liquor, raising the temp. of the residual mixt. to above the min. required to reduce Na_2SO_4 in the presence of CaO and below the temp. at which $CaCO_3$ dissociates and lixiviating the product. Cf. *C. A.* **22**, 4247.

Treating sulfite wood pulp liquor. WEBSTER E. BYRON BAKER. U. S. 1,685,800, Oct. 2. In order to recover sulfite material useful in prepg. sulfite cooking liquor, the waste liquor is neutralized with an alk. earth metal base such as lime to give a p_H of 9 or a greater alky. and to decomp. the reversibly combined SO_2 and increase the recovery of S as monosulfite; in prepg. the cooking liquor, the solids are treated with cooking acid contg. free SO_2 for producing bisulfites.

Apparatus (with a perforated rotating drum) for separating liquid from pulp fibers. JOHN H. HOYT (to United Filters Corp.). U. S. 1,685,084, Sept. 25.

Fertilizer from sulfite waste lye. MAX P. NITSCHE. U. S. 1,684,712, Sept. 18. See Can. 271,893 (*C. A.* **21**, 3743). Waste liquor obtained in the manuf. of sulfite cellulose is treated with an acid sulfate such as $KHSO_4$ and subjected to evapn. by which SO_2 is removed and a residue obtained that is suitable for use as a fertilizer.

Recovering sulfur dioxide from waste gases. GEORGE A. RICHTER (to Brown Co.). U. S. 1,685,754, Sept. 25. The hot digested contents of a sulfite digester are discharged into a blowpit, hot SO_2 and vapors liberated in the blowpit are passed in direct contact with and in counterflow to cold water supplied in such regulated amt. that the largest fraction of SO_2 is cooled without being absorbed and passes on in a cooled condition for absorption; some SO_2 is also recovered from the hot effluent water. Cf. *C. A.* **22**, 4247.

Digestion of crude materials for the manufacture of paper and other applications. SAMUEL MILNE. Fr. 635,307, May 23, 1927. Chem. processes for purifying cellulose for the manuf. of paper are intensified by a treatment with oscillating elec. currents.

Digesting wood chips. ROBERT WOODHEAD (to Venning D. Simons). U. S. 1,687,076, Oct. 9. In the manuf. of wood paper pulp by the use of liquors such as those of the "soda" or "sulfate" process wood chips are preheated in the presence of previously used digesting liquor to which a small quantity of fresh digesting liquor has been added, this liquor is drawn off and the material is then subjected to a final cooking with fresh liquor.

Pulp for paper making from wood or other materials. S. D. WELLS. Brit. 285,277, April 20, 1927. The material, preferably after suitable digestion, is disintegrated by the rolling action of rods in a "rod mill." "Gum chips" may be digested with 10% of Na_2SO_3 and 4% Na_2CO_3 or $NaHCO_3$; for pine wood 8% NaOH and 1% S, and for tamarack 8% of $Ca(HSO_3)_2$ and 2% of SO_2 (based on the wt. of the wood) are suitable. Straw, grass, bamboo, cornstalks, bagasse and other materials may also be softened, disintegrated or digested in the rod mill.

Paper-making apparatus. CHARLES L. HENDERSON (to Paper Patents Co.). U. S. 1,686,322, Oct. 2. A pulp strainer is described.

Pulping "engine" for treating paper pulp, etc. L. A. BARRY and L. A. BARRY. Brit. 284,992, Feb. 7, 1927.

"Beating engine" for treating paper pulp. HERBERT R. SIMONDS (to A. A. Simonds-Dayton Co.). U. S. 1,684,521, Sept. 18. Structural features.

Apparatus for screening paper pulp, etc. HAROLD D. WELLS. U. S. 1,685,736, Sept. 25.

Apparatus for screening paper pulp, etc. EDWARD B. FRITZ. U. S. 1,685,809, Oct. 2.

Control device for pulp refining "engines." ARTHUR J. LOMAN (one-half to Wm. Brown). U. S. 1,686,217, Oct. 2.

Regulating the flow of fibrous stock in paper making and similar processes. JAMES A. HEDGCOCK (to Management Engineering and Development Co.). U. S. 1,687,446, Oct. 9. Mech. features.

Controlling the flow of stock on paper-making apparatus. RALPH E. HEISEL (to Mead Pulp & Paper Co.). U. S. 1,687,447, Oct. 9. Mech. features.

Thickness regulator for paper-making apparatus. P. OFFENHEIMER, S. BLOCK and E. OFFENHEIMER (trading as Cellulosefabrik Okriftel a.M. Offenheimer). Brit. 285,311, Nov. 15, 1926.

Apparatus for making paper and spraying waterproofing material on it during manufacture. LESTER KIRSCHBRAUN. U. S. 1,686,818, Oct. 9.

Apparatus (with heated cylinders) for drying paper. WM. A. LORENZ (to Otaka Fabric Co.). U. S. 1,685,427.

Drying paper board as manufactured. R. KASTNER and H. SCHMOLKA. Brit. 284,319, Jan. 29, 1927. Paper board as it comes from a paper-board machine or other materials such as leather, veneers or fibrous intermediate products of the paper industry are pressed in piled sheets and then heated (suitably to about 70°) and further pressed to remove addnl. water and the heating is continued until the mass contains about 70% of paper substance. The temp. is then raised to 100-110° and the pressure reduced to allow the steam to escape, then increased and reduced alternately until the product reaches an air-dry condition. An app. and various mech. details are described.

Sizing paper. LOUIS-FERNAND-CHARLES GIRARDET. Fr. 635,419, June 2, 1927. The surface of paper is rendered more capable of absorbing the colloidal resin by adding an electrolyte such as $Al_2(SO_4)_3$. A colloidal soln. of resin is obtained by passing NaOH or Na_2CO_3 through it.

Coating paper or the like with bituminous substances. NAAMLOOZE VENNOOTSCHAP DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Fr. 635,968, June 14, 1927. Paper pulp is mixed with a gel of asphalt or other bituminous substance till 1 to 2 times the wt. of the paper pulp is absorbed. Waterproofing materials may be added. The gel is prepd. as described in Fr. 614,819.

Insulating paper. FELTON & GUILLEAUME CARLSWERK A.-G. Fr. 635,236, May 30, 1927. Colloidal cellulose pptd. by electrolytes, is used alone or with fibrous material for the manuf. of insulating paper. Cf. *C. A.* **22**, 3530.

Crinkled paper. WM. A. LORENZ (to Otaka Fabric Co.). U. S. 1,686,388, Oct. 2. In order to make paper elastic in all directions, a wet paper web is crinkled laterally, and longitudinally extending grooves are formed in the crinkled paper while it is still wet. An app. is described.

Colored paper. THOMAS HANS (to Container Corporation of America). U. S. 1,685,917, Oct. 2. In making paper from fluid, fibrous pulp, the pulp is incorporated with a part only of the coloring matter and sizing to be used, and after drying the advancing paper sheet, but before calendering, its surface is treated with a thin liquid contg. colored, paraffin-treated tapioca flour. An app. is described.

Washable colored paper. A. SANDERSON & SONS, LTD., AND H. A. SIMS. Brit. 284,435, Dec. 10, 1926. Wallpaper or other paper having a printed colored pattern is rendered washable by treating it with a dil. soln. of nitrocellulose contg. little or no gum or other gloss-producing agent. Several formulas of solns. are given.

Watermarked paper. ANTON PLEYER (to Gebr. Ebart). U. S. 1,687,140, Oct. 9. A body consisting of long fibers carries a deposited layer of short fiber material deposited as loose pulp upon a portion only of the body while the latter is still in pulpy condition; the fibers of the body and deposited layer are intimately interlocked and the short fiber layer merges into the main body of the material along an irregular line visible on the surface.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Explosives and their properties. I. GRAGEROFF. *Mining Congress J.* **14**, 715-6, 789(1928).—See *C. A.* **22**, 3530. E. M. SYMMES

Weight and density of explosives. F. MOUTHS. *Z. ges. Schiess-Sprengstoffw.* **23**, 80-1(1928).—The article explains the terms specific density, cubic density, loading

density and energy density as applied to explosives, and their relation to each other.
C. G. STORM

Report of Chief Inspector of Explosives of Victoria for 1927. REG. J. LEWIS. *Pamphlet* 10 pp.(1928).—No accident occurred during the year in manuf., storage, or transportation of the upwards of 9,000,000 lbs. of explosives and 10,000,000 detonators manufd. or imported. Of the recorded accidents in use, 4 occurred in loading gelignite and one in loading racka-rock into boreholes because of too high pressure put on the tamping rods. A number of accidents to children from playing with explosives, and especially detonators, are reported. CHARLES E. MUNROE

Smokeless powder. CYRIL KRAUZ. *Chemický Obzor* **1**, 2–9, 52–9, 127–31, 237–42, 267–70, 298–302; *Chem. Zentr.* **1927**, II, 2139.—A discussion of the phys. and chem. properties, *e. g.*, the shattering power, energy content, influence of the particle size and shape, with a description of the principles involved in the manuf. C. C. D.

Results obtained with pellet powder. B. L. LUBELSKY. *Coal Mining* **5**, 216–8 (1928).—Pellet powder produces much less smoke than granular black powder, allows quicker return to the face, reduces the slack coal produced from 33 to 30.5%, and reduces the consumption of powder. E. M. SYMMES

Production of trinitrotoluene in Austria during the World War. R. POLLER. *Z. Farben-Ind.* **20**, 127–31, 173–6(1928).—Details are given of the process for mfg. this explosive, used in Austria during the war. FREDERICK C. HAHN

The sodium salt of hydrazoic acid. EBERHARD KAYSER. *Z. angew. Chem.* **41**, 49(1928).—Tablets of NaN_3 about 0.005–0.010 g. in wt. when tested by the falling hammer method proved suitable for use in certain (safety) explosives. Such a tablet did not have a marked salty taste, but when one was swallowed there ensued within 5 min. violent heart stimulation, throbbing at the base of the brain, then loss of consciousness for 10 min., and rapid recovery. Less severe attacks recurred during the following hour. Symptoms were said to be similar to those caused by strychnine.
W. C. EBAUGH

Volumetric determination of diphenylamine and the centralites in smokeless gunpowder. OLDŘICH TUREK. *Chemický Obzor* **1**, 295–8; *Chem. Zentr.* **1927**, II, 999.—Ph_2NH is detd. by extg. it from smokeless gunpowder with Et_2O or distg. it with H_2O vapor. With the aid of an accurately standardized soln. of 8.35 g. of dry $KBrO_3$ and 30 g. KBr in 1 l. of distd. H_2O, Ph_2NH in a soln. contg. HCl is transformed into $(Br_2C_6H_3)_2NH$. The excess of Br is titrated back iodometrically. In the same manner, centralite I = $(C_2H_5)_2NCON(C_6H_5)_2$ is estd. The bromination is not quite so easy, but with exptl. conditions kept const., dibromocentralite is obtained in a reproducible way. The same method is used for detg. centralite II = $(CH_3)_2NCON(C_6H_5)_2$.
G. SCHWOCH

The Trauzl (lead block) test. R. NEUBNER. *Z. ges. Schiess-Sprengstoffw.* **23**, 1–5, 53–6, 72–7, 125–9, 194–8(1928).—Results obtained by the usual method of the Trauzl Pb-block test for *explosives* are not comparable. Instead of measuring the expansion produced by a standard wt. of explosive, N. dets. the wt. of explosive required to produce a standard expansion of 300 cc. The main variable thus eliminated is the gradual weakening of the walls of the Pb block with increasing expansion of the cavity. Corrections for (1) the original vol. of the cavity, (2) the expansion produced by the detonator, (3) the effect of the tin-foil wrapper, etc., are also eliminated. For purposes of comparison, the expansion value (in cc.) of 10 g. of the explosive may be calcd. from the 300 cc. value, and is designated as the strength number (Kraftzahl or "KZ"). The KZ values of explosive components of a mixt. are additive. KZ values for non-explosive components can be detd. by making Trauzl tests of their mixts. with "neutral" explosives such as glycol dinitrate, which give non-reactive products of explosion. Such KZ values are useful in formulating new explosive mixts. and predicting their properties. Old Trauzl values may be converted into new KZ values by a simple method of calcn. which is described. Purity of the Pb of the block is an important factor, variations in purity causing differences in expansion as great as 80 cc. The relations of the characteristic properties of explosives to their Trauzl block KZ values are discussed at length. In all explosion reactions N. assumes that CO is produced only by secondary reactions and not as a primary product, and that all products, including C, are gaseous at the instant of explosion. A method of calcg. *velocities of detonation* of explosives on the basis of KZ values is described. C. G. STORM

Testing the accuracy of measurement of the spark chronograph for determining the velocity of detonation (of explosives). H. KAST AND H. SELLE. Chem. Tech. Reichsanstalt. *Z. ges. Schiess-Sprengstoffw.* **23**, 217–9(1928).—A series of 36 measurements of the velocity of detonation of $Hg(ONC)_2$ *detonating fuse* were made with 1-m.

and 3-m. lengths of fuse with corresponding drum speeds of 70 and 210 r.p.sec., resp. The close agreement of results under such differing conditions demonstrated the high degree of accuracy of the Hartmann-Kempff frequency meter used. The mean error of all detns. was only 26 m./sec., with a mean velocity of 5251 m./sec. The error due to elec. disturbances is about 5 times the error of reading. Excellent agreement was also obtained in tests of pentaerythritol tetranitrate detonating fuse and other initiating explosives, whereas less uniformity was obtained with TNT fuse, gelatin dynamites and other explosives. This is attributed to differences in ease of detonation of the explosives. C. G. STORM

Tests with explosive gas mixtures. PAUL H. PRAUSNITZ. *Z. angew. Chem.* **41,** 1066–9(1928).—To protect against gas explosions where no destruction of the tube is to be feared and where there is no development of a red heat of the porous plate or screen the quartz filter tube (100 to 35μ diam. of pores) far exceeds the Fresenius tube with a wire screen. The degree of protection depends directly upon pore diam. For less brisant gases (illuminating gas-air mixts.) a glass filter with large pores suffices. The use of such tubes should facilitate the study of ignition of explosive gas-air mixts. and phenomena of surface combustion. E. M. SYMMES

Coal dust explosions. HANS STEINBRECHER. Braunkohlenforschungsinst., Freiburg (Sa.). *Braunkohlenarch.* **1927,** No. 17, 1–13; *Chem. Zentr.* **1927,** II, 1638; cf. *C. A.* 22, 500.—With the object of showing the cautions to be taken in preventing coal dust explosions, a comprehensive survey is made of the phenomena of such explosions, reference being made in particular to the great influence of the ignition point and distn. temp. upon the explosive power of various kinds of coal dust, especially brown coals. In contrast to gas, dust is not composed of mols. but of mol. aggregates, and it is therefore in a colloidally dispersed state and possesses all the characteristic properties of a reversible colloid. Its ability to oxidize increases greatly with increase in its fineness. The *ignition point and the time of ignition* (from the ignition point and from 200°) *of peat and various brown coals and mineral coals,* the *lower explosive limits,* the *volatile components,* the *H content,* the *combustible gases in the distd. gas,* the *ash of the dry coals,* the *distn. temp. and the bitumen content* were detd. Evaluation of the data shows in a convincing manner the *influence of the ignition point and distn. temp. on the explosive capacity.* C. C. DAVIS

Spontaneous electrification of dust clouds. S. C. BLACKTIN. Safety in Mines Research Board (London), *Paper* No. **43,** 3–19(1928).—This is a preliminary paper in which it is recorded that electricity is generated in coal dust clouds raised by a current of air, the quantity generated increasing with the speed of the air current and wt. of dust used, but varying with the sample of coal dust used. Sparks may be obtained from the charges so generated. In quant. expts. emery dust was used to sep. the coal dust particles, the latter tending by themselves to agglomerate. Expts. with *lycopodium* spores and with rice and potato starches indicates that the electricity generated per unit wt. of material passed increases with decrease in particle size, *i. e.,* this charge increases either with increase of surface area exposed, or with increase of number of particles. This relationship has been confirmed for coals by showing that increase in particle fineness, due to grinding, results in increase of elec. charge. C. E. M.

Explosibility of sulfide dusts in metal mines. E. D. GARDNER AND EDMUND STEIN. *Bur. Mines, Repts. Investigations* No. **2863,** 11 pp.(1928).—Explosions have occurred in blasting in massive sulfide ores of greater magnitude than could be accounted for by the charge of explosive used in making the blast. During regular blasting in such ores sulfide dust is produced and scattered about the mine, while SO_2 and H_2S appear in the atm. In these occasional heavy blasts the concns. of SO_2 in the afteratm. is very high. Gallery tests show that sulfide dusts can be ignited by blasting and that the combustion may be violent enough to be considered an explosion but it was not shown if such explosions are self-propagating. To prevent these explosions, settled dust should not be allowed to accumulate. All working places should be thoroughly wetted by sprinkling before the bore holes are loaded. And bore holes should be steamed and tamped to the collar. CHARLES E. MUNROE

Gaseous explosions. VI. Flame and pressure propagation. J. V. HUNN AND GEORGE G. BROWN. *Ind. Eng. Chem.* **20,** 1032–40(1928).—A cylindrical, steel bomb contained a window, 6 pressure elements along its length, and a spark plug at one end. Explosive gas mixts. were ignited in it, and flame and pressure curves registered automatically. As flame propagates a pressure wave is set up in the mixt. behind the flame front and travels at a greater velocity than the flame front. The pressure in the crest of this wave behind the flame front is greater than the pressure in the flame front of the unignited mixt. ahead of the flame. The halt and recession of the flame front is

caused by the pressure wave which follows the flame front at a greater velocity, overtaking and passing through the flame front. The max. pressure in mixts. promoting after-burning is developed some time after total inflammation of the charge.
E. M. SYMMES

The "normal" propagation of flame in gaseous mixtures. WILLIAM PAYMAN. *Ind. Eng. Chem.* 20, 1026–32(1928).—A preliminary attempt to trace the relation, if any, between speeds of flame in mixts. of air with H_2, CO, CH_4 and other paraffin hydrocarbons, C_2H_4 and C_2H_2, ignited under different conditions. The work is being continued and greater attention given to exceptions to these relationships.
E. M. SYMMES

The gaseous explosive reaction at constant pressure. F. W. STEVENS. *Ind. Eng. Chem.* 20, 1018–26(1928).—The course of the gaseous explosive reaction at const. pressure is described and followed by photographic time-vol. records in a transparent bomb. At const. pressure uniform rate of propagation, *s*, of the explosive reaction zone, measured relative to the active gases, is proportional to the product of their concns. (partial pressures): $s = k_1[A]^{n_1}[B]^{n_2}[C]^{n_3}\ldots$. The effect of inert gases and of composite fuels on the rate of gaseous explosive transformation is shown. E. M. S.

Warning when working with ether. HEINRICH DEMUS. *Z. angew. Chem.* 41, 426 (1928).—D. reports an explosion that happened while he was evapg. ether on a water bath. He thinks the explosion was caused by ether peroxide, which he found to be present in the ether employed. To remove the peroxide the ether is allowed to stand over an acid soln. of $FeSO_4$, from which it is distd. before use. In evapg. the ether, D. obtained a small amt. of an oily residue which smelled like stonecrop, and supposedly was ether oxide.
G. SCHWOCH

Self-ignition of oiled wool (OESTERMANN) 25. Spirit for combating celluloid fires (HAUCK) 23. Prevention of danger in the operation of gas generators (KATTENTIDT) 21. Explosion risk in the industrial preparation of absolute alcohol from sulfite spirit (SCHLUMBERGER) 16. Graphical evaluation of nitrating acids (BENDA) 23. The explosive properties of solid hypochlorite (WEICHHERZ) 18. The explosions occurring at the transferring of tar, tar oils and pitch by compressed air, their supposed causes and their prevention (LEYMANN) 21. Accidents in the production of Pb bromate (WITT) 18. Diethylene glycol dinitrate (U. S. pat. 1,686,344) 10. Treating tar [for making explosives] (Brit. pat. 285,000) 21. Combined carbide can and water receptacle suitable for refilling miners lamps (U. S. pat. 1,684,996) 1.

Explosive. N. F. ZHIROV. Russ. 4283, Dec. 31, 1927. Tetryl 100 parts and NH_4ClO_4 150 parts are moistened with a mixt. of AmOH and acetone, ground and dried.

Explosive. N. F. ZHIROV. Russ. 4284, Dec. 31, 1927. One hundred parts by weight of tetryl is mixed with 120 parts of $KClO_4$.

Explosives. REMINGTON ARMS CO. Brit. 285,232, Jan. 24, 1927. A priming mixt. without chlorate is formed with Hg fulminate, oxidizing salts such as $Ba(NO_3)_2$ and Pb nitrate, Pb thiocyanate and may contain Sb sulfide, other reducing agents, ground glass and a gum or gelatin glue.

Cyano nitrate explosives. FRANK H. BERGEIM (to E. I. duPont de Nemours & Co.). U. S. 1,685,771, Oct. 2. Explosives are prepd. contg. a cyano and a nitro group, *e. g.*, a dynamite may comprise cyano-ethanol nitrate 15, nitroglycerin 15, $NaNO_3$ 58, wood meal 11 and chalk 1%.

Dynamite. NORMAN G. JOHNSON and SAMUEL G. BAKER, JR. (to E. I. DuPont de Nemours & Co.). U. S. 1,687,023, Oct. 9. Ground popped corn is used for producing dynamite of low density, which, *e. g.*, may be formed with nitroglycerin, NH_4NO_3 and $NaNO_3$ also.

Gelatin dynamite. KENNETH R. BROWN (to Atlas Powder Co.). U. S. 1,686,952, Oct. 9. A nitroglycol such as ethylene glycol dinitrate is used to promote gelatinization in making explosives contg. nitrocellulose, nitroglycerin and a nitrated sugar.

Baffle plate apparatus for separating nitroglycerin or nitroglycol, etc., from residual acids used in their manufacture. A. SCHMID and J. MEISSNER (from Dynamit-A.-G. vorm. A. Nobel & Co.). Brit. 284,701, Feb. 5, 1927.

Nitrating glycerol and similar alcohols. A. SCHMID and J. MEISSNER (from Dynamit-A.-G. vorm. A. Nobel & Co.). Brit. 284,700, Feb. 5, 1927. An app. is described into the upper part of which glycerol, glycol or other material to be nitrated is introduced while nitrating acid is introduced into the lower part of the closed ni-

trating vessel which is provided with cooling coils and a stirrer. Brit. 284,702 specifies a column app. for washing nitrated products with soda soln. which may be agitated with compressed air or stirring devices.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Estimation of Katanol O(By) and investigation of its absorption by viscose silk. P. E. KING, G. M. WADADEKAR AND E. N. JOHNSON. *J. Soc. Dyers Colourists* **44**, 237–41(1928).—An aq. soln. contg. 1 g. of katanol O and 0.2 g. Na_2CO_3 was made up to 500 cc. To 10 cc. of this soln. was added 5 cc. of concd. H_2SO_4 and 100 cc. of water. The Katanol O was thereby pptd. and remained in suspension. This suspension was heated to 70° and was titrated with 0.1 *N* permanganate soln., *adding only 0.5 cc. at a time* and shaking until the color disappears. One cc. of 0.1 *N* permanganate is equiv. to 0.001156 g. of Katanol O. The absorption of Katanol O by viscose silk during 30, 60, 90 and 120 min. periods was 1.53, 1.81, 2.05 and 2.14%, resp. on the wt. of the silk. Up to 10% concn. of Katanol O the absorption by viscose silk varied directly as the concn. At concns. of Katanol O above 10% the absorption increased but not so rapidly. At temps. of 100, 85.70 and 60° for entering the viscose, the Katanol O absorbed was 2.26, 1.99, 1.69 and 1.62%, resp. Concn. of the bath increases the amt. of Katanol O absorbed. Increasing the concn. of Na_2SO_4 increased the percentage of Katanol O absorbed. Increasing the concn. of Na_2CO_3 decreased the percentage of Katanol O absorbed. In the titration of Katanol O soln. it was finally suggested to add the H_2SO_4 in a dild form so that the vol. of the liquor to be titrated shall be 300 cc. and the titration be commenced cold. Only toward the end of the titration was the temp. raised to 70°. L. W. RIGGS

The spectra of dyes. P. LAZAREV. *Chimie et industrie* Special No., 457–9(April, 1928).—An atlas has been prepd. of about 750 spectra, which were measured with a König-Martens spectrophotometer, the results being given in tabular and graphic form. The method used in making the detns. is described. A. PAPINEAU-COUTURE

Application of the T. C. B. photo-colorimeter to the determination of the strength of dyes. G. MARTIN. *Chimie et industrie* Special No., 460–5(April, 1928); cf. Toussaint, *C. A.* **21**, 3492.—A detailed description of the method of using the instrument for detg. the strength of dyes. A. PAPINEAU-COUTURE

The problem of color. F. RUDOLF. *Chimie et industrie* Special No., 454–6(April, 1928).—A criticism of Ostwald's color circle. A symmetrical color circle is suggested based on the polar diagram of the spectrum using a logarithmic formula such as (log. max. − log. min.)/(log. mean − log. min.) = C, in which C = 100/0, 100/25, 100/50, 100/75, 100/100, etc., for tones 1 (λ = 630), 2, 3, 4, 5, etc. The advantages and method of using this scale are discussed. A. PAPINEAU-COUTURE

Color purity and its measurement. L. BLIN DESBLEDS. *Textile Colorist* **50**, 170–2 (1928).—Color purity is discussed from the standpoint of the dyer. C. E. M.

Determination of light-fastness of dyes. E. TREPKA. *Przemysl Chem.* **12**, 249–52 (1928).—T. disagrees with Kaczkowski (cf. *C. A.* **22**, 2842) concerning K.'s estimate of value of artificial light for evaluating fastness of dyes. A. C. ZACHLIN

Fastness of dyes to light. W. KACZKOWSKI. Polytech., Warsaw. *Przemysl Chem.* **12**, 463–5(1928).—Reply to Trepka (cf. preceding abstr.) A. C. Z.

The behavior of dyestuff solutions. L. BLIN DESBLEDS. *Cotton* **92**, 299–303 (1928).—Optical analysis of dyestuffs is useful to the dyer in the prepn. of the dye bath and in explaining unexpected results of a mixt. of colors. An optical analysis of litmus in water soln., carried out by the Toussaint (T. C. B.) photo-colorimeter shows that red is the predominating color at all concns. Starting with water as reference, the curves exhibit increasing distortion with increase in concn. until a max. is reached at a concn. of 0.5 g. litmus in 100 g. H_2O examd. in transmitted light through a 4-mm. thickness of liquid. After the max., the curves tend gradually to flatten, keeping a high peak in the predominating (red) color and a low peak in the complementary (green) color. This behavior is not peculiar to litmus, but applies generally, similar curves being shown for violet diazol. The purity of a dyestuff is defined as the intensity difference between its predominating and its complementary colorations. The apparent purity of a dyestuff varies with its concn.; it passes through a maximum, which always corresponds to the same intensity of its predominating coloration. RUBY K. WORNER

Relation of p_H control to the dyehouse. HAROLD SCHROEDER. *Cotton* **92**, 799–800, 803(1928); *Dyer, Calico Printer* **60**, 49, 79(1928).—Descriptive. R. K. W.

Indigo sols. JAROMIR FRANĚK. *Chemický Obzor* **2**, 133–6; *Chem. Zentr.* **1927**, II, 1903.—Various methods for using indigo sols (sulfo esters of vat dyes) in the *dyeing of wool and cotton* are discussed, with the inclusion of some exact tech. directions for various methods of dyeing. C. C. DAVIS

The application of Indigosol O by the nitrite process. CHAS. E. MULLIN. *Rayon J.* **2**, No. 9, 13–5, 39–41(1927); *Textile J. of Australia* **3**, 140–4(1928).—The various processes and formulas proposed for the application of Indigosol O to cotton and rayon by the nitrite process, with a discussion of the exhaustion of the impregnating bath. CHAS. E. MULLIN

Loss of indigo in the vat. M. CHILIKIN. *Melliand Textilber.* **9**, 318–20(1928).—It has been known that the return of indigo from the vat is less than the amount of indigo originally dissolved. Part of the loss has been charged to oxidation brought about by H_2O_2, which possibly is formed when $Na_2S_2O_4$ decomposes in soln. Whether or not H_2O_2 is so formed, it is certainly formed when indigo white is oxidized in air. In fact quant. estn. is possible based on the reaction: $PbO_2 + H_2O_2 = PbO + H_2O + O_2$. The more alk. the vat the greater the loss of indigo. Since thioindigo shows a similar loss it is believed that amino N is not concerned in the reaction. Isatin was formed by the treatment of indigo white with H_2O_2. E. R. CLARK

Chrome yellow and orange removal on vat indigo blue. N. WOSNESSENSKY. *Bull. soc. ind. Mulhouse* **94**, 469–71(1928); cf. *C. A.* **22**, 3782. Sealed Note 1916 of July 20, 1905.—*p*-Nitro-*o*-anisidine red can be obtained on indigo blue by printing with the nitrosoamine on the fabric which has been prepd. with an org. acid. A reddish yellow can be similarly obtained with nitrosoamine J (take dichloroaniline (Farbw.) 16, hot water 40, 10° HCl 50, ice 36, $NaNO_2$ 8, and slowly add to 38° NaOH 450, 25% HCl 150, which has previously been cooled to 0°); and an orange-red can be obtained with a diazodianisidine, while chloroanisidine-nitrosoamine similarly gives a bright orange. **Chrome-brown removal on vat indigo blue.** *Ibid* 471–2. Sealed Note 1917 of July 20, 1905.—This is obtained by means of nitroso-β-naphthol as follows: print the unprepd. fabric with the following paste: nitroso-β-naphthol 200–400, soln. contg. 100 parts of neutralized $Na_2Cr_2O_7$ thickened with roasted starch 700–500, 23° Cr nitroacetate 100, steam 2 min., pass through a H_2SO_4-$C_2H_2O_4$ bath. By using Fe, Co, etc., salts, khaki, orange-red, deep olive, etc., shades can be obtained. **Report.** PIERRE BINDER. *Ibid* 472–3.—No anteriority was found, and no subsequent mention in the textile literature. The process described in Note 1917 considerably weakens the printed portions of the fabric through the attack of the fibers by the chromate during steaming. The use of the Indigosols has solved the problem of color removals on indigo in a simpler and more complete manner. A. PAPINEAU-COUTURE

β-Naphthol. A. BUNTROCK. *Z. Farben-Ind.* **20**, 3–5, 78–9, 126–7, 176–7(1928).—Details are given for equipment and for conditions of manuf. of β-naphthol, according to the latest developments in connection with this intermediate, based on a plant producing 1,000,000 kg. per year. This series of articles is being continued. F. C. H.

Azo-triphenylmethane and azo-pyronine dyes (meta series). RAJENDRA NATH SEN AND BENOYBHUSHAN GHOSH. *J. Indian Chem. Soc.* **5**, 487–96(1928).—A series of meta azo-aldehydes is coupled with (i) dimethylaniline and with *o*-cresotinic acid to give *azo-triphenylcarbinol dyes* and (ii) with resorcinol, pyrogallol and diethyl-*m*-aminophenol to give *azo-pyronine dyes*. Dimethylaniline gives greenish dyes on wool and silk, *o*-cresotinic acid reddish orange dyes, resorcinol brownish red and red, pyrogallol grayish black and diethyl-*m*-aminophenol violet or bluish violet dyes. The azo-aldehydes used are: *benzeneazosalicylaldehyde*, m. 127°; *naphthaleneazosalicylaldehyde, phenylhydrazone*, m. 96°, *oxime*, m. 201°; *diphenyldisazosalicylic acid-salicylic aldehyde* from diazotized benzidine, salicylic acid and salicylic aldehyde, oxime, m. above 300°; and *diphenyldisazobissalicylaldehyde, dioxime*, m. above 300°. P. J. C.

Dyes for viscose rayon—use of even-dyeing colors for special effects. WESTFORD. *Textile World* **74**, 1612–4(1928).—A table of most suitable dyes is included. R. K. W.

Accurate testing of dyed silks for fastness to perspiration presents many difficulties. FRED. GROVE-PALMER. *Textile World* **74**, 1671–3(1928).—Psychological and physiological factors interfere with the satisfactory testing of dyed silks for fastness to perspiration by actual association with the human body. Of the four laboratory tests adopted by research associations in America and Europe, that of the American Association of Textile Chemists and Colorists appears to approximate most nearly the actual conditions of perspiration. Although results of this test showed a marked similarity to those conducted by persons wearing the dyed fabrics, individual differences in the character of perspiration must still come into consideration. RUBY K. WORNER

Naphthol AS for wool and silk. J. RATH. *Melliand Textilber.* **9**, 595–6(1928).—

By use of low temp. and min. immersion, Naphthol AS may be successfully applied to wool or silk in spite of the alkalinity of the soln. The resultant dyeings produced by coupling show excellent fastness. E. R. CLARK

The physics and chemistry of dyeing. V. The structure of cellulose and substantive dyeing. KURT HESS. *Melliand Textilber.* 9, 573–5(1928).—The affinity of cellulose fibers for substantive dyes seems to be based on residual valences of OH groups disposed peripherally to the cellulose crystallite. As a number of these are required for fixation, only large mols. are suited to substantive dyeing, as has been observed. The effects of treatments of fibers which involve alteration of the form or internal arrangement of the cellulose crystallite are explainable by alteration in the concn. of available secondary valences. E. R. CLARK

Some practical dyeing methods. WILHELM SIEBER. *Melliand Textilber.* 9, 579–80 (1928).—For clearing the whites of alizarin red prints, "dry-chemicking" is recommended. For the purpose a bleaching powder soln. is treated with an excess of Na_2HPO_4. This is applied to the back of the goods, which are then quickly passed over well-wrapped dry-cans, and then washed. The whites of aniline black prints may be cleared with $KMnO_4$ E. R. CLARK

Dyeing silk with the alizarin dyestuffs. F. T. SYKES. *Dyer, Calico Printer* 60, 76–7, 96–7(1928).—The chief mordants used with alizarin dyestuffs on silk are alumina, iron and chrome. Details of the boiling-off, mordanting, dyeing and finishing processes are given. RUBY K. WORNER

Batik dyeing. JAROMÍR FRANĚK. *Chem. Obzor* 1, 189–94; *Chem. Zentr.* 1927, II, 1398.—Information is given concerning the method of batik dyeing and the raw materials and dyes suited for the different purposes. G. SCHWOCH

Dyeing cotton pile fabric. THOMAS J. NUCKOLLS. *Textile World* 74, 1675–7 (1928).—Descriptive. RUBY K. WORNER

Light pinks and mode shades on cotton. JAMES STAPLE. *Textile Colorist* 50, 252 (1928).—The Erban-Specht method is recommended for dyeing cotton light pink and mode shades with alizarin dyes. It consists of first treating the fiber with the dyestuff, and then impregnating with the mordant. A list of dyestuffs which can be used in this process and details of the procedure are given. RUBY K. WORNER

Tests on the penetration of dyestuffs through cotton oiled in the picker room. A. H. GRIMSHAW. N. C. State College Textile School. *Textile World* 74, 1655–6 (1928).—Comparative dyeing tests are described which show that a suitable emulsifiable mineral oil sprayed on cotton in the picker hopper will not interfere with the uniform distribution of direct, vat or sulfur dyestuffs, or their penetration through the fiber. RUBY K. WORNER

Dyeing fabric composed of rayon and cotton. G. RUDOLPH. *Leipzig. Monatschr. Textil-Ind.* 43, 167–8(1928).—While the even wetting of the material with the aid of such products as Nekal BX is useful in the dyeing of mixts. of cotton and rayon, it is no cure-all and level dyeing requires great attention to details. In the dye bath choice should be made between monopol oil, monopol brilliant oil and Marseilles soap based on the specific properties of the dyes used. The object of the selection is control of the rate of dyeing. Not over 0.5% Na_2CO_3 is permissible on light shades and not over 1.0% in any case. Light shades should be dyed below 25° and the temp. even for dark colors should not exceed 40°. In general the cotton is dyed more heavily than the rayon at lower temp. and the reverse becomes true as the temp. is raised. E. R. CLARK

Dyeing fast and uniform shades (on rayon). J. WM. WALSH. Textile Silk Dye Works. *Textile World* 74, 1591–2(1928).—General. RUBY K. WORNER

Dyeing and finishing (rayon) knit goods. ANON. *Textile World* 74, 1603–4 (1928).—Practical. RUBY K. WORNER

Developments in dyeing, delustering, scrooping, and related rayon processes. P. D. ATWOOD. DuPont Rayon Co. *Textile World* 74, 1610–1(1928).—A review. RUBY K. WORNER

Dyeing skein silk. T. COPLEY. *Dyer, Calico Printer* 60, 61(1928).—Suggestions for the selection of dyestuffs and assistants for producing light and heavy shades are given. Temp. plays an important part in the leveling of the dye. Only the softest water should be used. RUBY K. WORNER

Ammonium sulfite as leveling agent in wool dyeing. JOACHIM MÜLLER. *Dyer, Calico Printer* 59, 194(1928). RUBY K. WORNER

The dyeing of Phormium fiber. FRED. GROVE-PALMER. *Dyer, Calico Printer* 60, 80–1(1928).—Direct dyes are recommended for the paler shades, and acid colors for the darker ones. Basic dyes are seldom used except for topping off a shade. If fastness

is important, S dyes are best. A description of the cultivation, prepn. and uses of *Phormium* fiber (New Zealand flax) is included. Ruby K. Worner

Dyeing kapok. E. Meissner. *Leipzig. Monatschr. Textil-Ind.* **43**, 169(1928).—Direct dyes are ordinarily used. In applying them alky. must be avoided and it is well to use a large amt. of Na_2SO_4, up to 40–80%. The material is worked 1.0–1.5 hrs. at the boil. Acid colors may be applied with the aid of alum. The S colors are applicable if min. amts. of Na_2S and no Na_2CO_3 are employed. E. R. Clark

Lichen dyeing to-day: the revival of an ancient industry. A. R. Horwood. *Science Progress* **23**, 279–83(1928).—A description is given of the dye lichens, lichen colors and dyes and the methods used in the prepn. and application of these dyes. They are used chiefly for wool yarns, and home-spuns. Joseph S. Hepburn

Dyeing colored-toned window shades. George Rice. *Dyer, Calico Printer* **60**, 74–5(1928).—Descriptive. Ruby K. Worner

Textile industry of the Rhine Valley. *Leipzig. Monatschr. Textil-Ind.* **43**, special supplement to issue for July, 1928.—Describes factories, including newer industries, for manufacturing and processing textiles and making dyes and textile chemicals and schools and textile research labs. E. R. Clark

Common impurities in textile trade chemicals. E. T. Ellis. *Indian Textile J.* **38**, 296(1928).—The most usual impurities in $CaCO_3$, $Al(ClO_3)_3$, $BaCl_2$, CrF_3, BaO_2, $Al_2(SO_4)_3$, $Cr(CNS)_3$ and NH_4 vanadate are discussed. Ruby K. Worner

Illumination from above in the microscopy of textiles. Alois Herzog. *Melliand Textilber.* **9**, 748–52(1928). E. R. Clark

Ultra-violet light in textile examinations. H. Sommer. *Melliand Textilber.* **9**, 753–5(1928).—While the examination of samples of textile materials, especially such as may not be destroyed, under the light of the quartz tube arc gives data at times of interest, the method has distinct limitations. For example, the dye present may entirely obscure the fluorescence color peculiar to the fiber in question and even give an entirely false conclusion. No certain distinction between flax and hemp under such illumination can be made. Bleached linen and cotton are not distinguishable, nor are mohair and wool. The reddish white luminescence of copper rayon is distinct from the yellowish cast of that of viscose rayon. For the identification of dyes the method is of but little real value. However, American cotton dyed to imitate Egyptian is readily detd., as is dyed wool as a substitute for camel hair. Alkali damage to wool corresponding to 30% loss in strength is not determinable, nor is acid damage to wool. Ultra-violet light makes oil spots on fabric especially distinct. Sulfite cellulose pulp is not distinguishable from soda pulp after the former has been exposed to bright light. Otherwise a distinction can be recognized. Instead of the Hg arc, a type giving a more continuous ultra-violet spectrum would be worth studying. E. R. Clark

Some measurements of the transmission of ultra-violet radiation through various fabrics. W. W. Coblentz, R. Stair and C. W. Schoffstall. *Bur. Standard J. Res.* **1**, 105–24(1928). E. J. Crane

Many imitations and grades of purity among fibers make identification by microscope best. John H. Skinkle. *Textile World* **74**, 1811–2(1928).—The microscopic appearances are given of wool, mohair, camel hair, true silk, Tussah silk, sea silk, cotton, mercerized cotton, kapok, flax, hemp, jute, ramie, Manila hemp, sisal hemp, New Zealand flax, shoddy and the rayons, including acetate, nitro, cupra and viscose. Ruby K. Worner

Conditioning small samples of fiber. Horace Fleming. *Textile Colorist* **50**, 253(1928).—A simple method, ascribed to Rawson, for detg. the dry wt. of small samples is described. Ruby K. Worner

Influence of active oxygen upon fiber strength. B. Walther. *Seifensieder Ztg.* **55**, 249–51(1928).—Washing expts. (laundered 100 times) were made with "Persil" and with soap alone on cotton and half linen, test strips of 2.5 in. × 0.8 m. being used. The results show a gradual but markedly greater decrease in tensile strength in all cases where active O_2 ("Persil") had been used than in cases where soap alone was employed. P. Escher

The injury of textile fibers by light and weather. H. Sommer. *Z. ges. Textilind.* **30**, 465–8, 482–3; *Chem. Zentr.* **1927**, II, 1417.—The destruction of fibers which occurs on weathering is a process which takes place largely on the surface exposed to light, and is due to the short wave lengths, principally ultra-violet rays. Moisture, contrary to previous opinions, furthers the deterioration, especially with wool and bast fibers. The compn. of the atm. is likewise a factor; the purer the atm., the less the destruction. The sensitivity of the investigated fibers to weathering varies greatly. Expressed in the hours of sunshine which are required to cause a loss of 50% in tensile strength they

fall into the following order: silk (200), jute (400), artificial silk (900), cotton (940), flax (990), hemp (1100), raw wool (1120), chromed wool (1900). In this evaluation the varying thickness of the substances was not taken into consideration. J. S. R.

Various causes of deterioration of fabrics. B. Setlik. *Chimie et industrie* **Special No.**, 466 (April, 1928); cf. *C. A.* 21, 3465.—Three cases are described: one was due to the presence, in the size, of $MgCl_2$ and $MgSO_4$, hydrolysis of which had given rise to the formation of free acid; the 2nd was due to the cutting of the silk warp by the hard and highly twisted rayon filler; the 3rd was traced to the action of sunlight. A. Papineau-Couture

Skin irritation caused by textile fabrics. S. R. Trotman. *Textile Recorder* **45**, No. 541, 70, 65(1928).—An investigation of a large no. of cases showed that most of them concern wool, fur or hair, rarely cotton or silk goods. Woolen underclothing and hosiery, both dyed and undyed, are frequent causes of irritation. Low-grade wool may contain H_2SO_3 from the stoving process, which, when combined, may be liberated by perspiration, and when free, is absorbed directly by the skin. Peroxide bleaching destroys the ability of this wool to produce irritation. In dyed hosiery, the source of irritation may be unremoved H_2SO_4, sol. Cr salts, dichromates or other mineral salts used as mordants. Occasionally septic sores may be traced to pathogenic bacteria which have found access to the finished garment. Incomplete removal of phenylenediamine is the chief cause of outbreaks of dyed fur dermatitis. It is suggested that $Hg(NO_3)_2$ and Cu and Zn salts used in the "carrotting" process for the velour hats now in vogue may cause a dermatitis on the exposed portions of the neck. R. K. W.

Oxycellulose and the determination of the degree of mercerization. E. Ristenpart. *Melliand Textilber.* **9**, 577–9(1928).—If mercerizing is accompanied by over-bleaching, Lange's test with iodo-$ZnCl_2$ soln. gives misleading results. For example a mercerized but over-bleached yarn was given the same color rating after washing out the stain as was the same yarn prior to mercerizing. Apparently mercerized cellulose when oxidized loses its power of forming a semi-stable compd. with I_2. Microscopic study is the best method of detg. mercerization. E. R. Clark

What characteristics to look for in acceptable sizing material. H. D. Martin. *Textile Colorist* **50**, 237–8(1928).—Desirable characteristics of an ideal sizing compd. are strength-imparting, penetrativeness, fluidity, adhesiveness, freedom from brittleness, no tendency to scale, transparency, odorlessness, elasticity, absence of stickiness, smoothness, cleanliness, preservativeness (not easily deteriorated), vermin-proofness, good stripping quality, vanishment (in some cases it is desirable to have the sizing material shake off and disappear in weaving process), color absorption and inexpensiveness. R. K. W.

An ingenious hand-driven sizing machine. Anon. *Indian Textile J.* **38**, 127–8 (1928).—An illustrated description of the Amalsad patent hand-driven, forced-hot-air sizing machine, which was developed to suit the requirements of hand-loom weavers. Ruby K. Worner

The iodometric evaluation of oxidizing agents for desizing fabrics. R. Haller, J. Hackl and M. Frankfurt. *Melliand Textilber.* **9**, 758–9(1928); cf. *C. A.* **22**, 3050.—While the course of the hydrolysis of starch with oxidizing agents is not definitely known, iodometric methods for following the rate of hydrolysis, based on the formation of maltose, give practically valuable results. E. R. Clark

Hypochlorite bleaching. J. Auerbach. *Melliand Textilber.* **9**, 769–70(1928).—The effect of HOCl on the N compds. present in cotton after alk. digestion is oxidizing and chlorinating. The former leads to the formation of ketone acids of type formula RCOCOOH, while the latter results in formation of chloroamines having type formula RCH(NHCl)COOH. Along with the production of the oxidation products, NH_3 is formed, which with HOCl yields NH_2Cl. Treatment with $NaHSO_3$ eliminates all chloroamines, which in themselves have no bleaching action. E. R. Clark

Newer views on bleaching of vegetable fibers. V. Ježek. *Chem. Obzor* **3**, 197–9 (1928).—A review. Jar. Kučera

"Pinking" of bleached cottons. L. J. Matos. *Textile World* **74**, 1675(1928).—Evidence is presented against the prevailing opinion that the discoloration is due to mildew. Oxidation of the cotton by H_2SO_4 and reaction with aniline fumes in the air has been suggested as a cause. Another possibility is that bleached cotton packed in shipping cases with waterproofed paper linings might, under the heat of the warehouses, react with some of the volatile constituents of the waterproofing material and form a colored compd. Ruby K. Worner

Forty years in cotton-print industry. Preparation of formulas, production, piece-work, determination of cost of production. Henri Zublin. *Tiba* **6**, 405–17, 567–85,

777–81, 881–9, 1029–39(1928).—This article gives the result of 40 yrs.' experience in plants mfg. a wide variety of articles in Austria, France, Germany and Italy.
A. Papineau-Couture

Purification of cotton. V. Shaposhnikov and S. Yeserskii. *Z. Farben-Ind.* **20**, 60–4, 131–3, 177–80(1928).—A study is made of the kiering and bleaching of cotton to det. the best conditions for conducting these processes. The optimum conditions found for kiering are as follows: 6 hrs. with 3% NaOH, 3 atms., ratio of cellulose to NaOH 100:8. The criteria used for judging the kiering conditions were the oxidizability of the waste liquor, a measure of the loss of cellulosic material, and the consumption of NaOH due to reaction. A study of the increased consumption of Cl with increased time of bleaching showed that the use of concns. of Cl over 1.0 g. per l. is unnecessary. With 0.5 g. Cl per l., after 4–6 hrs. the concn. was 0.0142%, while after 18 hrs. 0.0134%. S. and Y. assume, therefore, that the consumption of Cl at first is due mainly to adsorption, and this Cl hardly takes part in the bleaching. In favor of such an assumption is cited the fact that cotton removed from the bleach liquor retains the odor of Cl even after a great deal of washing, a treatment with antichlor (hyposulfite) soln. being necessary to remove the odor of Cl. After the removal of the cotton, the bleach liquor possesses a milky turbidity, the particles consisting of $CaCO_3$, very short fibers, and a small ppt. insol. in warm dil. HCl. The amount of this ppt. was too small to be identified. This series of articles is being continued. Frederick C. Hahn

The detection and determination of acidity and alkalinity in cotton and other cellulose materials. S. R. Trotman. *Dyer, Calico Printer* **60**, 116–7(1928).—The work of Coward and Wigley (*C. A.* **16**, 3000) on spotting tests, the method of Procter and Hirst for the indirect detn. of mineral acid by incineration and titration with methyl orange, and the method of Innes by means of H-ion concn. are cited. R. K. W.

The effect of organic acids on cotton at 105–110°. E. Ristenpart and K. Petzold. *Leipzig. Monatschr. Textil-Ind.* **42**, 389, 390(1927); *Expt. Sta. Record* **57**, 899.—Cotton treated with 1% acetic, formic, or lactic acid could be dried at temps. up to 110° without substantial damage. Tartaric acid should evidently be avoided in the final washing. Its detrimental effect sets in especially after evapn. of the water and with consequent concn. of the acid. While initial damage is caused by the rapid evapn. in drying the cotton at 100° and over, further heating results in recovery such that the cotton is no longer exposed to attacks of the acid. Acid-treated cotton persistently retained traces of acid after drying. Mercerized cotton seemed in general to be resistant to acids. H. G.

Chemistry of kier boiling (of cotton). M. Chilikin. *Melliand Textilber.* **9**, 397–404(1928).—Sepn. and identification of the components of kier liquor show that during the boiling the following actions take place: (1) olein, etc., are saponified; (2) esters of cerotic, carnaubic, and melissic acids are to a slight extent saponified, but for the most part are emulsified; (3) N-contg. substances are hydrolyzed and the resulting amino acids are neutralized; (4) pentosans are decomposed completely; (5) hydrocarbons and gossypyl alc. are emulsified. The emulsification is promoted by an unidentified N-contg. substance which loses part of its emulsifying power as the liquor is cooled.
E. R. Clark

The nature of mineral-oil stains on unbleached cotton fabrics and the direction in which investigations should be carried out. H. Sunder. *Chimie et industrie* **Special No.**, 417–4(April, 1928); cf. Mennecke, *et al.*, *C. A.* **22**, 3784. A. P.-C.

Influence of laundering on cotton fabrics, especially with washing agents containing sodium perborate. P. E. Raaschou and V. Ahrend Larsen. Polytechnical College, Copenhagen. *Ind. Eng. Chem.* **20**, 916–22(1928).—Extensive washing tests are reported for heavy unbleached and light cotton fabrics soiled with mixed fruit juices for slight soiling and with tea and claret for more intense soiling. To obtain a basis of comparison, washing tests were carried out with soda, NaOH, water glass, and soap solns., both sep. and mixed with each other, partly with and partly without $NaBO_3$. To det. the purely mechanical wear occurring in home laundering, some hand-washing tests were conducted. Studies were also made of the processes of decompn. of perborate in the various washing prepns. and mixts. thereof; of the effect of ions on the rate of decompn. of the perborate; of the relation between loss in weight and loss in strength during washing; and of the ash and incrusted substances formed by adsorption on the fabric.
Ruby K. Worner

From cotton to rayon. R. A. Kölliker. *Z. Farben-Ind.* **20**, 135–6(1928).—A review of the chemistry, methods of prepn. and properties of different varieties of rayon used up to the present time. Frederick C. Hahn

Modern methods and trends in processing cotton-rayon woven fabrics. Winn W.

CHASE. *Textile World* **74**, 1605–7(1928).—Desizing, scouring, bleaching, dyeing and finishing are considered. RUBY K. WORNER

A year's progress in rayon by producers, equipment builders, and mills. JAMES W. COX, JR. *Textile World* **74**, 1595–7(1928).—A résumé. RUBY K. WORNER

Science offers increasingly powerful weapons for the attack on rayon research problems. EDWARD R. SCHWARZ. *Textile World* **74**, 1607–8(1928).—The modern well-equipped textile-testing lab. includes optical equipment of varied nature, elec. measuring devices, x-ray, spectrophotometric app., etc. RUBY K. WORNER

Methods of identifying rayons as to group, type and probable manufacturer. ARTHUR K. JOHNSON. *Textile World* **74**, 1600–3(1928).—A procedure is suggested for the systematic examn. of an unknown sample. Phys., chem. and microscopic tests are described, and the need of caution in interpreting the results is stressed. R. K. W.

Graphical methods greatly simplify the solution of rayon mathematical problems. A. S. MARK. *Textile World* **74**, 1598–1600(1928); cf. *C. A.* **22**, 3783.—A logarithmic chart is proposed for finding equiv. cotton and worsted counts and counts of combination yarns of any denier of rayon. RUBY K. WORNER

Stability test for rayon. P. KRAIS. *Leipzig. Monatschr. Textil-Ind.* **43**, 257 (1928).—Nitro rayon is not unique in being in some cases subject to loss of strength in heating and accelerated aging tests. Some viscose samples tested similarly showed losses of one-third their original strength. The acetate fibers examd. showed good stability. E. R. CLARK

Progress in making rayon warps—refinements in preparatory processes. RAY WINDER. *Textile World* **74**, 1587–8(1928).—The features of the Van Vlaanderen rayon warp-sizing machine are described and compared with those of the ordinary cotton slasher. RUBY K. WORNER

Preparation of cross sections of rayon. ALOIS HERZOG. *Melliand Textilber.* **8**, 429–30(1927); cf. *C. A.* **22**, 2843.—A slight twisting of the bundle of fibers after coating with collodion and before setting takes place gives the sections rigidity. Oblique microscope illumination adds to definition of unstained sections. E. R. CLARK

Proper oiling of rayon yarn declared greatest problem facing knitting trade. ANON. *Rayon* **5**, No. 8, 20–3(1927).—Pure mineral oils do not appear to give the best results and many knitters are using blended or processed oils. Some knitters are having success with a mixt. of good-grade neatsfoot and mineral oils. It should not be necessary to use a boiling soap soln. to scour out the oil, as this may cause streaky dyeings. CHAS. E. MULLIN

The sizing of artificial silk on the warp beam. WILLIAM BENNETT. *Indian Textile J.* **38**, 302–4(1928).—General discussion of the selection of sizing material and description of a suitable type of warp sizing machine. RUBY K. WORNER

The physico-chemical nature of natural silk solutions in neutral, acid and basic solvents. P. P. VON VEIMARN. *Kolloid Z.* **46**, 40–3(1928).—Fresh silk may be swollen in water or dil. salt solns. whereas ordinary silk is insol. Solns. of silk in neutral salt aq. solns. may be likened to the colloidal and true solns. of AgI in KI and $AgNO_3$ solns., as the fibroin possibly forms complexes with the salt. In consequence of its amphoteric nature fibroin forms unstable complexes with acids and bases through water elimination similarly to $Al(OH)_3$. L. F. MAREK

Investigation of the behavior of silk coagulum in polarized light while undergoing dehydration and aging. P. P. VON VEIMARN. *Kolloid-Z.* **46**, No. 1, 36–8(1928).—During dehydration and aging of a silk coagulum from a sirupy liquid, the mass passed through the stages of a viscous fluid, a rubbery, elastic jelly, to a hard, brittle mass. The following was observed in a microscopical examn. of the swelling of silk in a hot aq. soln. of NaI: with swelling the structure became more pronounced as bundles of thin, ultra-microscopical fibrils; these bundles twisted into spirals which remained wound about the fiber; the fiber became a sirupy mass and the bundles melted into long drops. In polarized light the bright interference colors were observed to fade as swelling progressed and to disappear at complete swelling with only dark and bright spots remaining. A coagulum from silk dispersed in NaI at 130° and coagulated in 4 *N* sodium citrate was spun into a thread and examd. in polarized light. The more or less spiral lines are seen. The interference colors begin to appear and soon cover the entire thread. It was shown that fibers formed from silk coagulum are not essentially distinguishable from natural silk with regard to interference colors and inner structure. L. F. MAREK

Formula for calculating the yield of loading in silk from the ash content. M. DAVID. *Tiba* **6**, 1011, 1013(1928).—If p = wt. of loaded silk taken and c = wt. of anhyd. ash

found, the yield of loading on the amt. of raw silk originally taken is given by $R\% = 100\left(\frac{0.75}{1 - (1.27c/p)} - 1\right)$. A. Papineau-Couture

The tin weighting of silk. Fred. Grove-Palmer. *Indian Textile J.* **38**, 236 (1928).—General. Ruby K. Worner

Lustering silk by mechanical means. James R. Spencer. *Textile Colorist* **50**, 181(1928).—The fiber is stretched in contact with polished metal rollers, after which it may be steamed. Chas. E. Mullin

Effects of sodium hydroxide on linen. M. M. Chilikin. *Melliand Textilber.* **9**, 592–4(1928).—Linen already has many of the phys. properties of mercerized cotton, and investigations of the mercerization of linen have but little com. significance. Efforts have, however, been made to utilize the cottonizing action of concd. NaOH solns., and further studies may give data of significance to cotton mercerizing. The full mercerizing action takes place on linen at lower concn. than is noted on cotton, the absorption curve reaching practically a max. at about 12% NaOH. Mercerized linen is more readily dyed in pure full shades with vat dyes than is the untreated material. E. R. Clark

Hydron colors on linen fabrics. Anon. *Textile Colorist* **50**, 173–5(1928).—Methods and formulas for dyeing. Chas. E. Mullin

The properties of wool. L. Meunier and G. Rey. Univ. de Lyon. *Chimie et industrie* Special No., 722–7(April, 1928).—See *C. A.* **22**, 1047. A. P.-C.

The visible alterations in wool after being treated in acid chemic vats. Alois Herzog. *Textile Recorder* **45**, No. 541, 63–5; **46**, No. 542, 57–61(1928).—See *C. A.* **22**, 1046. Ruby K. Worner

The protection of woolen goods from damage by alkalies. S. R. Trotman. *Textile Recorder* **46**, No. 543, 57–8(1928).—Alkali damage can be inhibited or limited by the use of some chemical which forms a compd. with the wool not readily attacked by alkali by adding to the bath a substance which forms an adsorption compd. or a loose chem. compd. with the alkali, or by the addn. of a chemical which inhibits hydrolysis of the soap. Examples of each type of protection are given. Ruby K. Worner

Analytical study of the washing of raw wool. L. Leites, N. Zaussoilov and E. Jurzeva. *Leipzig. Monatschr. Textil-Ind.* **43**, 212–3, 263–4(1928).—Analyses were made of the liquor and of the wool at various stages of its treatment in a continuous washer. The greatest percentage of unsapond., that is emulsified, fat is obtained at the first squeeze roll, and as the wool is carried along the unsapond.-fat content decreases rapidly. For max. recovery of lanolin under favorable conditions for purification, special attention should be given to the first washing compartment and its squeezing system. The wool entering the dryer contained 46.8% H_2O and 0.188% alkali. E. R. Clark

The practice of successful wool scouring. A. W. Davison. *Dyestuffs* **29**, 57–9 (1928).—"The first requirement for successful scouring is that the stock be well opened out before being delivered to the train." Scouring liquors should be changed before they become too dirty so as to avoid trouble in the dyeing and other subsequent processes. Chas. E. Mullin

The Netz method of scouring wool. Eduard Langer. *Textile Recorder* **46**, No. 542, 53–4(1928).—The Netz method, invented in Germany prior to the war, has not become established because of a series of adverse circumstances. According to this method, the wool is supported by grates in a hermetically sealed extractor and is surrounded during the scouring process by a circulating layer of air, and during the additional removal of the fat solvent, it is dried with a circulating current of air. The solvents are chlorinated hydrocarbons, especially di- and tri-chloroethylene. It is claimed that wool thus treated is of much better quality and finer than that worked by other methods, and that this process is less expensive in spite of the greater cost for the plant. For patents on the process, see *C. A.* **8**, 828, 1860. Ruby K. Worner

Self-ignition of oiled wool. H. Oestermann. *Leipzig. Monatschr. Textil-Ind.* **43**, 162–3, 210–1, 258–9(1928).—Tests with Mackey app. confirm the superiority of olive and peanut oils from the standpoint of hazard of self-ignition of the fiber, and the dangerous catalytic action of Mn and Fe resinates and similar driers. Of inhibitors for self-ignition S showed special effectiveness. Self-ignition is rare in wool contg. over 10% moisture. E. R. Clark

The action of bichrome on wool. C. York. *Dyer, Calico Printer* **59**, 262–3; **60**, 6–7; 32–4(1928).—General discussion. To insure uniform results, old chrome baths are to be avoided. Tendering of wool is ascribed to its reaction with NaOH formed by dissocn. of $Na_2Cr_2O_7$. Practical experience is cited in support of this hypothesis. Ruby K. Worner

Finishing mohair velour. Wilhelm Kegel. *Leipzig. Monatschr. Textil-Ind.* **43,** 191(1928).—The objects of the finisher should be to impart the desired luster and softness, and yet to leave the nap erect and resistant to crushing. After shearing, the material is steamed for 0.5–1.0 hrs. at 1.5–3.0 atm. with dry steam. The app. should be free from air, and the steam removed by suction. In any hot treatment care must be taken to avoid crushing or folding until the material is cooled, as otherwise stubborn wrinkles are formed. After dyeing operations passage through 1% glycerol soln. is desirable. E. R. Clark

Density of yarn packages. Anon. *Textile World* **74,** 1679(1928).—The "Durometer," an instrument for testing the density of wound packages of yarns, such as bobbins, spools, cones, tubes, quills and beams, is described and illustrated. R. K. W.

Throwster clearances on crepe. Warren P. Seem. *Textile World* **74,** 1673–5 (1928); cf. *C. A.* **22,** 3784.—The factors affecting throwster clearances and the "fixing" of returns are discussed. Ruby K. Worner

***p*H and detergent action.** Chas. E. Mullin. *Textile Colorist* **49,** 665–8(1927).—The theory of detergent action (surface tension, emulsification and pedesis) is discussed and the effects of p_H upon the cleansing action of detergent solns. are described. Apparently the cleansing action of a detergent soln. increases almost as a straight line when the cleansing action (ordinates) is plotted against the p_H (abscissae) of the soln. The falling-off in cleansing action of detergent solns. in continuous use is explained and the "break" in continuous scouring is described and discussed. There is no relation between the p_H of the soln. and the break, which appears to be due to the exhaustion of colloidal soap from the soln. More research is needed along these lines. C. E. M.

Wetting agents. Albert Landolt. *Melliand Textilber.* 9, 759–65(1928).—A general survey of the theory and practice involved in the manuf. and use of wetting agents as aids in dyeing, mercerizing, carbonizing, etc. In discussing the various classes of substances used it is noted under soaps that the size of particle must approach colloidal dimensions before wetting is efficient. Examples of soaps contg. fat-dissolving chlorinated hydrocarbons are Lanadin, Hydrapthal, Terpuril, Cycloran and Sovental. For the evaluation of sol. oils, the estn. of SO_3 is to be recommended. Prestabitol is an example of this type of material. Some prepns. contain also chlorinated hydrocarbons. Alkylnaphthalenesulfonic acids, typified by Nekal and Neomerpin, are finding increasing usage. There are several wetting materials which must be classed as chem. individuals. Prominent examples are the "carnites" such as Tetracarnite, derived from pyridine, and products based on cholic acid and diethylamine. Tests of wetting agents should cover chem. analysis, stability against working conditions such as hard water, drop-number detn., wetting-power detn., and practical works trial. Of methods for detn. of wetting power, those of Erban, Herbig and Ristenpart are most widely used. The first notes the sinking time for a sample, and is subject to the difficulty that entrapped air effects the results. The second, sometimes called the centrifugal method, dets. the wt. of water absorbed. The third is a refinement of the time for sinking test and employs a short bit of cotton thread slightly weighted at the free end. The wetting power of prepd. solns. shows no general relation to concn., and drop numbers do not coincide with practical results. The alkylnaphthalenesulfonic acids work better at low temp. than at high. E. R. Clark

Testing waterproofed coatings. Kenneth E. Marsden. *Textile Recorder* **46,** No. 543, 67(1928).—The specified test for army, police, naval or air-force great-coats is that from a height of 6 ft., water is dropped on to a pattern, tilted at an angle of 45 degrees, at the rate of 18 drops per min., each 18 drops to measure 1 cc. Diagrams of the dropping app. are given. Ruby K. Worner

Tarpaulins. Fred. Grove-Palmer. *Textile Recorder* **46,** No. 542, 37–8(1928).—A general description of the French, Scottish and American methods of prepg. tarpaulins. Ruby K. Worner

Some useful recipes. Clifford R. Carter. *Dyer, Calico Printer* **60,** 104–5 (1928).—Tested recipes are given for the following: *sizing for finishing and polishing twines,* including sash cords, fine and coarse twines and jute twine; *thread polishing,* including medium glacé and silk finishes, and glacé or hand-finished thread; *cleaning of calendar rollers; dressing for jute warps; tannin treatment* for preserving sails, ropes, nets, etc.; *weather-proofing twine; grease for hemp ropes; removal of mineral oil stains from linen, etc.; dressing* for thin finish for fine linen; and *prevention of mildew.* Ruby K. Worner

ZUBLIN, HENRI: **40 Jahre Kattundruck.** Singen-Hohentwiel: Berchtold and Gommeringer. Reviewed in *Bull. soc. ind. Mulhouse* **94,** 379–80(1928).

Dyes. MARCEL BADER and CHARLES SUNDER. Fr. 32,721, Oct. 23, 1926. Addn. to 551,666. Leuco derivs. of vat dyes are treated with pyrosulfuryl chloride to obtain derivs. used for dyeing and printing. In examples, the leuco deriv. of dibromoindigo and of 4,5',7'-trichloroindigo in a mixt. of dimethylaniline and chlorobenzene is so heated. Leuco derivs. of the thioindigo and anthraquinone series may also be used.

Dyes. J. R. GEIGY A.-G. Brit. 284,614, Jan. 31, 1927. Various specified isorosindulines in which at least 2 sulfonic groups are present are used for the production of phenonaphthosafranines according to the process described in Brit. 265,986 (*C. A.* **22,** 503). The positions 4, 8, 9, and 11 to 15 may be substituted by alkyl, hydroxy, alkyloxy, carboxy, acidylamino or sulfo groups or by halogen. A 1-chloro-3-diethylisorosinduline-12-sulfonic may be prepd. by coupling 3'-sulfophenyl-2-naphthylamine with nitroso-*m*-chlorodiethylaniline and after sepn. converted into the corresponding 6,12-disulfonic acid and this product may then be coupled with 1-methyl-2-ethylamino-5-aminobenzene-4-sulfonic acid. The dye thus formed dyes wool from a H_2SO_4 bath fast greenish blue shades. Other examples also are given. Brit. 284,615 specifies the use of an isorosinduline having no acid substituents in the 1, 2 and 4 positions. A sulfonic group may be present in the 6 and also in the 8, 9, 12, 13 and 14 positions and a neutral group such as methoxy or ethoxy may be in the 1, 2 and 4 positions while any univalent group may occupy the positions 7 to 10 and 11 to 15. 3-Diethylisorosinduline-12-sulfonic acid is made by coupling 3'-sulfophenyl-2-naphthylamine and nitrosodiethylaniline, converted into the 1,12-disulfonic acid, and the latter then coupled with 1-methyl-2-ethylamino-5-aminobenzene-4-sulfonic acid to produce a safranine.

Dyes. I. G. FARBENIND. A.-G. Brit. 284,242, Jan. 25, 1927. Anthraquinone derivs., some of which are suitable for dyeing "acetate silk," are produced by the interaction of hydroxyanthraquinones upon ethylenediamine; *e. g.*, quinizarin may be introduced into ethylenediamine hydrate; crystals of a salt-like product of the 2 compds. at first sep. but on warming the new product is obtained. When quinizarin can no longer be detected spectroscopically the mass is dild., filtered, washed with HCl and water and recrystd. Compds. are similarly prepd. from purpurin and 1,2,4,5,8-pentahydroxyanthraquinone or 1,4,8-trihydroxyanthraquinone by reaction with ethylenediamine hydrate.

Dyes. I. G. FARBENIND. A.-G. Brit. 284,288, Jan. 27, 1927. Thioindigoid dyes are made by condensing arylthioglycolic acids with *o*-diketones such as acenaphthenequinone, or isatin and its homologs or substitution products or α-derivs., in the presence of P_2O_5, preferably together with a solvent or dispersing agent. Several examples are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 285,389, Feb. 14, 1927. 2-Thionaphthene-3-indoleindigoid dyes are made by condensing 6-aminohydroxythionaphthene with a 5,7-dihaloisatin and then introducing 2 Cl atoms into the 5,7-positions on the thionaphthene side, or by condensing 5,7-dichloro-6-aminohydroxythionaphthene with a 5,7-dihaloisatin. Sulfuryl chloride may be used for the chlorination. Examples are given, the products of which give brown dyeings on cotton from the vat.

Dyes. I. G. FARBENIND. A.-G. Brit. 285,502, Feb. 18, 1927. Vat dyes giving blue to violet or black shades on cotton are obtained by heating polyhalopyranthrones or their derivs. with such quantities of N-contg. compds. (suitably α-aminoanthraquinone, 1-amino-4-methoxyanthraquinone or 4-amino-1,1'-dianthrimide) in which

at least one reactive H atom is connected to the N atom that several or all of the halogen atoms are substituted by nitrogenous radicals.

Dyes. I. G. FARBENIND. A.-G. Brit. 285,504, Feb. 18, 1927. Dyes are made by condensing at both amino groups, diaminophenyl or its derivs., with halonitrosulfonic acids of the benzene or naphthalene series in which the halogen atoms are exchangeable. Numerous examples are given for producing dyes dyeing animal fibers greenish yellow to brownish red tints. In producing the dyes, org. solvents may be used as may also acid-binding substances such as NaOAc or Na_2CO_3 and catalysts such as Cu. The process may be effected under pressure.

Dyes. I. G. FARBENIND. A.-G. Brit. 285,555, Nov. 16, 1926. Vat dyes are made by heating a 2-halo-1,9-pyrazoleanthrone with an acid-binding agent such as KOAc and a metal compd. such as Cu acetate (suitably by boiling in $PhNO_2$). A dye may be obtained which dyes cotton fast red shades from a blue hyposulfite vat.

Dyes. I. G. FARBENIND. A.-G. Fr. 635,225, May 30, 1927. Clear and stable violet dyes are prepd. by brominating monoalkyl-2,2-indolethionaphthenindigos in H_2SO_4 as solvent till 2 atoms of Br are absorbed. Examples are given of the bromination of the 7-methyl and the 6-methyl compds.

Dyes. I. G. FARBENIND. A.-G. Fr. 635,311, May 25, 1927. 2,2′-Dimethyl-*ms*-benzodianthrone or its derivs. are treated with alk. agents, such as Na_2CO_3, AcONa or KOH with or without solvents or diluents, whereby the Me groups combine to form another 6-C ring. The new compds. called *allo-ms*-naphthodianthrones color cotton in shades from orange to brown from the vat. They can be transformed into new vat dyes, *ms*-anthradianthrones, by treating with $AlCl_3$, etc., or by submitting them in H_2SO_4 soln. to the action of light or oxidizing agents. *ms*-Anthradianthrones are also prepd. by treating 2,2′-dimethyl-*ms*-naphthodianthrone or its derivs. with alk. agents. The dyeing properties are improved by introducing halogens. Several examples are given.

Dyes. SOC. ANON POUR L'IND. CHIM. À BÂLE. Brit. 284,656, Feb. 2, 1927. Chlorinated violanthrones which dye marine-blue shades fast to water are made by treating with Cl, at a temp. above 80° (suitably 130° in examples given), and in the presence of an inert diluent such as $PhNO_2$, dibromoviolanthrone, dichloroviolanthrone or like halogenated violanthrones instead of violanthrone itself as described in Brit. 262,774 (*C. A.* **21**, 3750). The product may have a Cl content between that of a tetra- and penta-deriv.

Dyes. SOC. ANON POUR L'IND. CHIM. À BÂLE. Brit. 285,096, Feb. 12, 1927. 1-Arylamino-4-aminoanthraquinones which contain in the aryl nucleus at least one amino group or a group derived from the amino group are made by condensing a 1-hydroxy- or 1-alkyloxy-4-aminoanthraquinone or a 1,4-diaminoanthraquinone with an aromatic diamine such as phenylenediamine, naphthylenediamine or benzidine, or a deriv., substitution product or homolog. The products may be used for dyeing cellulose esters and ethers such as cellulose acetate and in varnishes. Several examples are given of dyes giving blue colors.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 285,097, Feb. 11, 1927. Mordant dyes giving fast brown shades when chrome-printed on cotton are made by coupling 2 mol. proportions of the same or different diazo compds. of the benzene series contg. the residue of an *o*-hydroxyarylcarboxylic acid with 1 mol. proportion of a 1,3-dihydroxy compd. of the benzene series. Several examples are given.

Azine dyes. J. R. GEIGY A.-G. Brit. 285,486, Feb. 19, 1927. By treatment with a sulfonating agent such as fuming sulfuric acid, an addnl. sulfonic group is introduced into the 16-position of a tri- or tetra-alkylphenonaphthosafranine (which may contain various substituents) which may also contain sulfo groups in the 1- or 2-positions and possibly also in 8-, 9-, or 11- to 15-positions.

Azo dyes. MELCHIOR BOENIGER (to Chemische Fabrik vorm. SANDOZ). U. S. 1,686,947, Oct. 9. Unsym. azo dyes are formed from equimol. proportions of a tetrazodiaryl such as diazotized benzidine or tolidine and a 2′-methyl-3′-amine-5′-sulfo-1-phenyl-5-pyrazolone in which either CH_3 or COOH is attached to the 3-position of the pyrazolone ring. Dyes thus produced dye cotton without mordanting in shades varying from orange to red and dark brown and can be diazotized and developed on the fiber. Their Na salts are readily sol. in water.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 284,247, Jan. 25, 1927. Azo dyes are produced in substance or on the fiber by coupling with an arylide of 2,3-hydroxynaphthoic acid a diazotized *as-m*-xylidine substituted by a second amino group in *m*-position to the first with one or both of the H atoms of the second amino group replaced by

alkyl, aralkyl, benzoyl, substituted benzoyl or arylsulfonic acid groups. Examples are given of dyes producing bluish red shades on cotton.

Azo dyes. HUGO SCHWEITZER and WILHELM NEELMEIER (to Grasselli Dyestuff Corp.). U. S. 1,685,071, Sept. 18. An aromatic diazo compd. such as diazotized *o*-sulfanilic acid is coupled with the methylpyrazolone obtained from 4′-methyl-2-aminodiphenylsulfone-4-sulfonic acid or other suitable pyrazolone of a sulfonated aminodiarylsulfone. The dyes thus formed dye wool fast yellow.

Mordant azo dyes. ALFRED PHILIPS and MARTIN DABELOW (to Grasselli Dyestuff Corp.). U. S. 1,684,778, Sept. 18. The diazo compd. of 2-amino-1-phenol-4-sulfonic acid, 4-chloro-2-aminophenol-6-sulfonic acid or 4-nitro-2-aminophenol or other suitable *o*-aminohydroxy compd. of the aromatic series is combined with 2,6-dihydroxynaphthalene-3-carboxylic acid. The dyes thus formed may be used to obtain green shades by the one-bath chroming process.

Yellow azo dye. ERICH FISCHER and CARL E. MÜLLER (to Grasselli Dyestuff Corp.). U. S. 1,684,762, Sept. 18. A dye suitable for dyeing and printing "acetate silk" is prepd. by coupling diazotized *p*-nitroaniline with 1-nitro-2,4-diaminobenzene.

Dye composition. WINTHROP S. LAWRENCE. U. S. 1,684,401, Sept. 18. A compn. suitable for use as a printing paste comprises a basic-dye-Zn-tannate lake together with gum tragacanth or other suitable thickening agent and a glycolic compd., *e. g.*, ethylene glycol and ethylene chlorohydrin.

Naphthophenazine dyes. WILHELM NEELMEIER and THEODOR NOCKEN (to Grasselli Dyestuff Corp.). U. S. 1,686,026, Oct. 2. *p*-Alkyloxyarylamino-substituted 1,3-naphthylenediamine compds. are used to produce fast naphthophenazine dyes by condensation with *p*-nitrosoaminoaryl compds. or *p*-aminoazo compds. or by joint oxidation of the naphthylenediamines with *p*-diamines. The dyes produced are generally dark powders with metallic luster, sol in water with blue to violet colors, sol. in H_2SO_4 with green colors and dye wool from acid baths very level greenish blue to violet shades of good fastness to light. Several examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 635,620, June 8, 1927. Hydroxyl compds. of ketones of the perylene series are alkylated so as to introduce a long chain consisting of a short hydrocarbon portion joined by an O or S atom to a second hydrocarbon portion. The dyes obtained are stable to light and are sol. in org. solvents, making them suitable for the prepn. of colored varnishes. In examples the oxidation product of dibenzanthrone obtained according to Fr. 451,798, is alkylated with $MeC_6H_4SO_3CH_2$-CH_2OR, in which R is Me or Et. The product dyes cotton blue from the vat. If R is Bu a brilliant powder relatively sol. in benzene is obtained, which gives a green varnish. If this ester contains glycol ditoluenesulfonate, it forms a blue dye as by-product, which can also be obtained from $(CH_2Br)_2$ and dihydroxydibenzanthrone. Cf. *C. A.* **22**, 3786.

Sulfuretted dyes and dye intermediates. I. G. FARBENIND. A.-G. Brit. 285,382, Feb. 14, 1927. Indophenols and leucoindophenols are obtained from a base, the nucleus N of which belongs to a hydrogenated ring system by condensing it with a quinone haloimide or a *p*-nitrosophenol, or by its simultaneous oxidation with a *p*-amino phenol. *E. g.*, *p*-aminophenol is simultaneously oxidized with hexahydrocarbazole, N-ethylhexahydrocarbazole, tetrahydroquinoline, octahydro-α-naphthoquinoline and with octahydroacaridine and the resulting indophenol is isolated as its leuco deriv. Other examples are given. The products may be used as intermediates in the manuf. of S dyes.

Emulsifying agent for dyes. BRITISH DYESTUFFS CORPORATION LIMITED, JAMES BADDILEY and ERNEST CHAPMAN. Fr. 635,264, May 31, 1927. Mineral oil fractions capable of sulfonation are sulfonated and condensed with an alc. The two operations may be carried out in one. Examples are given of the condensation of sulfonic oils with PrOH and iso-PrOH, and of the use of the products as emulsifying and wetting agents for dyes.

Dyeing. MARTIN BATTEGAY (to Calco Chemical Co.). U. S. 1,686,224, Oct. 2. Fibrous material such as silk, cotton or artificial silk is dyed in a single operation by use of a sulfurized phenol and an acid dye or salt of such a dye, *e. g.*, acid violet 4B, together with Na_2CO_3 or other suitable alkali.

Dyeing. I. G. FARBENIND. A.-G. Brit. 285,442, Feb. 16, 1927. Fast blue dyeings are produced by treating with $CuSO_4$ or other suitable Cu compd. fibers such as cotton dyed with a trisazo dye contg. as first component an aminosalicylic or amino-cresotinic acid or a deriv. and as end component 2-amino-5-naphthol-7-sulfonic acid or a deriv. or substitution product. Examples are given.

Dyeing. JOSEPH NÜSSLEIN (to I. G. Farbenind. A.-G.). U. S. 1,684,881, Sept.

18. Fibrous material such as yarn or fabric is treated with a mixt. comprising aniline or other suitable aromatic amine which is practically insol. in water, together with water and an emulsifying agent such as Na dibutylanilinesulfonate and the amine is then oxidized.

Dyeing. N. N. Vorozhtzov and K. L. Gribov. Russ. 3822, Oct. 31, 1927. Textile materials, furs, feathers, cotton, layers of gelatin, albumin, collodion, etc., are treated with aromatic mono-, di-, or polynitro-, mono-, di-, or polysulfonic acids or their salts and exposed to the action of sunlight.

Dyeing fabrics. Ferdinand Edlinger. Austrian 108,906, Oct. 15, 1927. Fabrics which have been heated and pressed in a patterning calender are treated in a dyebath which is first cold and relatively concd. and later warmed and dild. The pressed and unpressed parts of the fabric are thus differentially dyed.

Dyeing fabrics in a centrifugal apparatus. Tandy A. Bryson and John J. McKeon (to General Laundry Machinery Co.). U. S. 1,687,122, Oct. 9. Mech. features.

Dyeing artificial silk. I. G. Farbenind. A.-G. Brit. 284,652, Feb. 2, 1927. Artificial silk made from cellulose derivs. such as cellulose esters and ethers and their conversion products is dyed with azo dyes contg. not more than one sulfonic or carboxylic group, obtained by coupling diazo compds. with substituted or unsubstituted cyclic compds. comprising a benzene nucleus condensed with a 5-membered heterocyclic ring, of which one H atom can react with the diazo compd. Cyclic compds. which may be employed include β-ketocoumarane, oxindole, hydroxythionaphthene, 3-hydroxy-1-sulfone-naphthene and methylketol, and among other components of dyes mentioned are: sulfanilic acid, 6-chloro-2-toluidine, 2,5-dichloroaniline, aniline-*o*-sulfonic acid. Examples are given for dyeing in various yellow shades.

Dyeing cellulose esters. British Celanese, Ltd., and G. H. Ellis. Brit. 284,376, Oct. 21, 1926. Cellulose formate yarn, cellulose propionate yarn or other yarns, fabrics, films or the like of cellulose esters other than the acetate, are dyed, printed or stenciled by the use of an aq. dispersion of an insol. or "relatively insol." org. coloring matter or compd. prepd. by pretreating the coloring matter with dispersing agents such as NH_4 sulforicinoleate, Na sulfonaphthalenericinoleate or Na sulforicinoleate or xylene and Turkey red oil. Various other substances also may be added. When dyeings are effected by the azoic process, the insol. component is thus dispersed and is applied to the material before or after the other component. Several examples are given.

Dyeing and printing cellulose ethers. H. Dreyfus. Brit. 285,104, Oct. 8, 1926. Yarns, fabrics, films or other products contg. cellulose ethers such as ethylcellulose are dyed printed or stenciled with an aq. dispersion of an insol. or "relatively insol." coloring matter or compd. prepd. by pretreating the coloring matter with a dispersing agent. Numerous examples, details and modifications are given. Cf. *C. A.* **22,** 3051.

Colored films. C. Dreyfus (to British Celanese, Ltd.), and G. H. Ellis. Brit. 285,431, Feb. 16, 1927. Various azo or other suitable coloring substances which are insol. in water are dissolved by use of org. solvents or of solubilizing agents and used in coloring solns. of cellulose esters or ethers during their formation into films or sheets for *photographic* or other purposes. Insol. pigments may also be added to produce opaque effects.

"Mineral dyeing" of textile material. Clarence B. White (to Vivatex Processes, Inc.). U. S. 1,686,540, Oct. 9. A difficultly sol. metallic salt, such as an oxidized product made from $FeSO_4$, is brought into soln. with the aid of a "solvent stimulant" such as formic acid and Ba acetate and this soln. is used to impregnate textile material which may then be treated with alkali or soap to form an insol. compd. in the fiber.

Preparing cellulosic fibers for dyeing. Chemische Fabrik vorm. Sandoz. Brit. 284,358, Jan. 28, 1927. Cotton, mercerized cotton, "viscose silk" or other cellulose fibers are rendered capable of being dyed by acid dyes by treating them simultaneously with a sulfonyl halide and a tertiary org. base. Among the substances which may be used are: the chloride or bromide of any aliphatic or aromatic sulfonic acid with Et_3N, Me_2NPh, C_5H_5N and C_9H_7N. $PhNO_2$ or other inert solvent may be present. Cf. *C. A.* **22,** 2847.

Fixation of basic dyes on cotton fabrics. Ivanovo-Voznesenskii Government Textile Trust. Russ. 4342, Sept. 15, 1924. The goods after being treated with the acetate soln. of the basic dye together with the acetate soln. of the metal salt which forms an insol. hydroxide (*e. g.*, of Al, Cr or Zn) and after steaming, are passed over a hot soln. of any product of phenol or its homologs obtained by boiling an alk. phenol soln. with S.

Applying dye solutions to yarn on bobbins. James S. Johnston (to Eclipse Tex-

tile Devices, Inc.). U. S. reissue 17,096, Oct. 2. See original pat. 1,613,707 (*C. A.* **21,** 827).

Mordanting cellulose derivatives. CAMILLE DREYFUS, GEORGE RIVAT and ERNEST CADGENE. Fr. 636,058, June 16, 1927. Cloth or the like cellulose derivs., such as acetate, is treated with one or more mordanting salts and one or more swelling agents. Acetates or other salts of Cr, Al or Fe are used as mordanting agents, and formic acid, AcOH, furfurol, phenol, pyridine, or aq. solns. contg. furfural, and either AcOH or formic acid are used as swelling agents.

Mordanting cellulose derivatives. CAMILLE DREYFUS, GEORGE RIVAT and ERNEST CADGENE. Fr. 636,057, June 16, 1927. Cloth or the like contg. cellulose derivs. such as acetate is treated with a concd. soln. (40–55%) of Fe salts, particularly the chloride, sulfate or nitrate. The cloth is then dyed with mordant dyes.

Printing textile materials. J. G. KERN and C. J. SALA (to E. I. DuPont de Nemours & Co.). Brit. 285,041, Feb. 9, 1927. Vat dyes are pasted with a dispersing agent, preferably glycerol, and ethanolamine (which may be a crude product obtained by distg. the reaction products of ethylene oxide and NH_3).

Color printing cloth. ÉTABLISSEMENTS PETITDIDIER (ANCIENNE MAISON JOLLY-BELIN). Fr. 32,658, May 7, 1926 Addn. to 615,301. Cloth having a basis of silk or wool is passed, after printing the cellulose acetate, into a bath of $KMnO_4$ and then into a soln. of $NaHSO_3$ to remove the color, arising from the printing, from the basis of the cloth.

Wetting out and dyeing or other treatments of fibrous materials, leather, etc. RAINER H. POTT (to Chemische Fabrik Pott & Co.). U. S. 1,686,836, Oct. 9, Sulfonic acid salts of isopropylnaphthalene or other sulfonic acid salts of substituted aromatic polynuclear hydrocarbons are added to acid fiber-treating baths such as are used in carbonization of woolen fabrics or in dyeing. Cf. *C. A.* **21,** 826.

Carbonizing woolen fibers. RAINER H. POTT (to Chemische Fabrik Pott & Co.). U. S. 1,686,837, Oct. 9. An acid bath is used in the presence of sulfonic acid salts of isopropylnaphthalene or other suitable sulfonic acids of substituted aromatic polynuclear hydrocarbons which serve to improve the uniformity of penetration of the treating liquid.

Treatment of fibrous materials. DOUGLAS MCINTYRE PROCTOR and THE CARBORUNDUM COMPANY. Fr. 635,324, May 31, 1927. Rollers for drawing or otherwise treating fibrous materials are covered with a layer of hard material such as SiC or fused Al_2O_3 and a binder such as a silicate, gum lac or vulcanite.

Disintegrating vegetable fibers. I. G. FARBENIND. A.-G. Fr. 635,302, May 20, 1927. Vegetable fibers are treated with a soln. of an agent capable of decomposing the fat, *e. g.*, dibutylnaphthalenesulfonic acid or one of its salts. An emulsifying agent may be added.

Textile fibers from skins of sharks, etc. A. EHRENREICH. Brit. 284,297, Jan. 27, 1927. The skin is subjected to the action of an enzyme such as trypsin to disintegrate the intercellular substance, is then tanned and the fibers are sepd. by carding and opening machines. Various details are given.

Impregnation of vegetable fibers to prevent rotting. S. E. PISAREV. Russ. 4547, Sept. 15, 1924. Fibers are impregnated with Cu salts of naphthenic acids in an aq. soln. of ammonia or in an aq. ammonia soln. of Cu oxide.

Impregnation of vegetable fiber, netting, etc., to prevent rotting. S. E. PISAREV. Russ. 4,548, Sept. 15, 1924. Fibers, etc., are impregnated by pressing in a suspension of basic Cu carbonate in water and CO_2 followed by drying to dispose of the CO_2.

Processing fabrics. CHARLES F. RYLEY (to Henry Dreyfus). Can. 283,818, Oct. 2, 1928. Sizes, oils or other dressings are removed from woven or knitted fabrics consisting wholly or partly of cellulose acetate, by winding the fabric on a perforated pipe and causing benzene, xylene or other org. solvent to percolate outwardly through the roll under a relatively small pressure.

Treating fabrics to render them less likely to develop faults. GEORGE H. ELLIS (to Celanese Corp. of America). U. S. 1,686,149, Oct. 2. Fabrics such as those of cellulose acetate are treated with strong aq. solns. of dispersing agents, *e. g.*, sulfonated fatty acids or sulfonated derivs. This treatment serves to prevent development of various faults.

Apparatus for drying web material. WILHELM BOCK. U. S. 1,686,597, Oct. 9.

Degreasing textiles. I. G. FARBENIND. A.-G. & Fr. 635,456, June 2, 1927. Ethylene chloride is used for degreasing textiles. Cf. *C. A.* **22,** 3789.

Machine for soaking textiles. CORNEILLE LONGTON. Fr. 635,659, April 6, 1927.

never fell below 97. When burned cane is being milled, condensate water should be used for purging. J. F. BREWSTER

Factors influencing the filtration of raw sugar solutions. R. H. KING. *Planter and Sugar Mfr.* **79,** 221(1927).—A readily filtering sugar demands good clarification in its manuf., the P_2O_5 content of the juice being the major factor in securing this. Suspensions which impede filtration are the result of poor defecation, soly. of certain substances, which are pptd. by concn. in the clarified juice, re-soln. of the settlings during washing, and also the introduction of insol. matter from the low-grade sugar remelted. Suspensions capable of forming ppts. that retard filtration are formed as the result of the digestion of fine bagasse particles during treatment with CaO at high temp. B. C. A.

An apparatus for determining the activity of filtering or decolorizing matter in technical laboratories. ALEŠ LINSBAUER AND JOZEF VAŠÁTKO. *Listy Cukrovar.* **46,** 659–63(1928).—A description of the app., its operation and application in refineries is given. FRANK MARESH

The decrease of economic losses in the diffusion of sugars. FR. PAULÍK. *Listy Cukrovar.* **46,** 647–50(1928).—A descriptive article concerning the com. operation of batteries of diffusion cells in operation since 1909. FRANK MARESH

The future sugar diffusion conducted with respect to density. ALOIS RAK. *Listy Cukrovar.* **46,** 666(1928).—A plea is made for progress in continental diffusion cells involving the principle of keeping both reacting media in the individual diffusion chambers in continuous and progressive motion in the direction of their changing densities and transferring them so that each one shall enter the diffusion cell by itself. FRANK MARESH

The effect of heating on the specific conductance of sugar solutions. L. SATTLER AND F. W. ZERBAN. *Facts About Sugar* **23,** 686–9, 713–5(1928).—In mildly acid solns. comparable to those occurring in the factory, inversion of sucrose induced by heating in the presence of certain salts causes a decrease in the cond., principally on account of the increase in total solids. With reducing sugars, there is usually observed a slight destruction of sugar and an increase in cond. This increase is particularly marked in the presence of amino acids. All this applies to solns. around 40 Bx. With solns. around 5 Bx. or less, the observed changes are much smaller and in the opposite direction. When the solns. are initially alk. the heating causes a large destruction of invert sugar with consequent large increase in cond.; even with sucrose a distinct increase in cond. takes place. J. F. BREWSTER

Apropros the electrolysis of sugar juices. JULIEN BERGÉ. *Sucr. Belge* **47,** 283–5, 302–4(1928).—The Say-Gramme method for purification of sugar juices consists of electrodialysis using Fe electrodes. One chamber becomes alk., the other acid, which dissolves the Fe electrode, forming $FeSO_4$. Part of the org. matter ppts. in the central juice chamber and part in the membranes. The current is reversed and the $FeSO_4$ and KOH react in the central chamber, producing a flocculent ppt. of $Fe(OH)_2$, resulting in beautiful defecation. The current requirement is 1.25 kw. hrs. per ton of beets. Fe consumed is proportional to current consumption. The life of the parchment membranes depends on the rapidity of obstruction and the care in handling and cleaning. Improvements required are: Employment of durable dialyzing membranes and sol. electrodes of low-cost material, or which can be regenerated. Their salts must be non-poisonous. E. A. FIEGER

Hydrogen-ion concentration and the defecation of cane juice. H. S. PAINE AND R. T. BALCH. *Planter and Sugar Mfr.* **79,** 127–32, 148–50(1927); cf. *C. A.* **21,** 2570.—To ensure a max. clarification and to prevent inversion losses the juice should be limed (provided that sufficient filtering capacity be available) to p_H 8–9, measured either before or after heating, but the H-ion concn. for max. defecation varies with different juices, and in any case the possibilities of color formation and of scaling of evaporator tubes and heaters are to be considered. B. C. A.

Balancing total soluble solids. E. E. BATTELLE. *Facts About Sugar* **23,** 302–3 (1928); cf. *C. A.* **22,** 2678.—The adoption by cane sugar manufacturers of a system of reports which will include a balance of total sol. solids received in cane is urged as of great tech. importance in that it may disclose and correct losses not apparent in the present scheme of lab. reports. Tabulated data and discussion are given. J. F. BREWSTER

Reducing sugars in raw sugars. F. W. ZERBAN AND WM. J. HUGHES. *Sugar* **30,** 56–7(1928).—By applying Browne's correction formula (cf. *C. A.* **14,** 1057) $S/[G + 40 + (3S^2/1000G^2)]$, where S is mg. sucrose by Clerget, G the uncorrected mg. of glucose corresponding to wt. of reduced Cu to Allihn's table for dextrose and then multiplying

by the reducing ratio 1.044 to convert dextrose into invert sugar a set of tables and a set of graphs are presented from which the % of invert sugars corresponding to mg. reduced Cu may be read directly. A single graph upon a very large scale is constructed for each % sucrose content from 94 to 98%. J. F. BREWSTER

Abnormal color of raw sugar. K. ŠANDERA AND A. RŮŽIČKA. *Listy Cukrovar.* **46,** 561–4(1928).—For many years, sugar from N. W. Bohemia has had an ash gray color instead of a normal yellow. The malady is regional and has been noticed to be assocd. with areas frequented by hail. The juices show a lowered alky. and a green color. Submitted samples showed a low ash content. From cond. titration curves, the compn. of the sugar and non-sugars was judged to be the same. The absorption spectrum of the abnormal sugar showed a lessened absorption in the violet and blue, resembling that of Lundén's "amethyst color." The coloring matter is adsorbed by the sugar crystals during crystn., giving rise to colors in the product, but not any of the coloring matter remains in the molasses. FRANK MARESH

Acetic acid method for recovery of sugar from molasses (procedure of Friedrich and Rajtora). F. MIZZACTROLI, I. MUTTI AND A. PROMBO. *Sucr. Belge.* **47,** 321–8 (1928).—The method consists of concn. of molasses, addn. of AcOH and C_6H_6, sepn. of AcOH of the mother liquor and working up of the non-sugar. The concn. of molasses prevents diln. of the AcOH and also soln. (in part) of the sugar after pptn. The C_6H_6 is added to reduce the viscosity. A study was made of the influence of C_6H_6, AcOH and temp. upon yield of sugar obtained. The best conditions are: Brix 90–95°, glacial AcOH 60%, C_6H_6 5%, and temp. 50–60°. The work confirms that of Friedrich and Rajtora (cf. *C. A.* **19,** 743). E. A. FIEGER

Graphic method for the control of cane sugar factories. M. O. GIROL. *Bull. assoc. chem. sucr. dist.* **45,** 391–5(1928).—A graphic method is briefly described whereby one may tell at a glance the extn. of the mills and the amt. of imbibition water added. All the data necessary are: brix of various mill juices, brix of mixed juice and quantity of mixed juice. The graphs from day to day have relative significance and give handy and easily pictured information. The purity of last mill juice should be recorded as it serves as a means of knowing whether much sugar is being lost in the bagasse, and also of giving an insight as to how well the imbibition water is mixed with the cane juice. E. A. FIEGER

The analysis of normal cane juice. E. E. DOMINGUEZ. *Facts About Sugar* **23,** 206–8(1928).—Indirect methods and formulas are discussed. In the proposed method it is required that the wts. of cane, mixed juice and maceration H_2O be positively known. The chem. data required are analysis of mixed juice, residual juice and bagasse. Details of calcn. should be obtained from the original paper. J. F. BREWSTER

Notes on the p_H of cane juice. R. T. BALCH. *Sugar* **30,** 8–9(1928).—At a Porto Rican central in 1927, the av. p_H of all samples was found to be 5.06, ranging from 4.97 to 5.13 for fertilized plots and from 4.99 to 5.12 for control plots. One would expect the p_H of crusher juices to be practically const. in any one factory, and any abnormal lowering of the value to be an indication of cane deterioration after cutting. J. F. BREWSTER

Spain's cane-sugar industry. J. VAN HARREVELD. *Indische Mercuur* July 25, 1928; *Facts About Sugar* **23,** 882–3(1928).—H. gives the name, daily capacity (which varies between 50 and 250 metric tons), ownership and location of each factory. The method of paying for the cane, equipment of the factories, and forms of products are briefly described. M. J. PROFFITT

Progress in cane-sugar agriculture. H. P. AGEE. *Facts About Sugar* **23,** 946–7, 951(1928).—A general discussion of Hawaiian investigations on new cane varieties, new *fertilizers* and *fertilization practice,* new practices in irrigation, the relative merits of long and short cropping, and the planning and execution of exptl. work in the fields. M. J. PROFFITT

The value of measuring growth of cane. H. J. RODRIGUES. *Planter and Sugar Mfr.* **80,** 21–2(1928).—Following the Javan practice, height of growth of cane in Louisiana over varying time periods was measured and the procedure is recommended as enabling overseers to check growth conditions such as fitness, fertilizing and tillage of soil and weather conditions. J. F. BREWSTER

Deterioration of sugar content in P. O. J. canes. G. B. SARTORIS. *Facts About Sugar* **23,** 662–5(1928).—By experimenting with 4 P. O. J. varieties in Louisiana it was found that the cane withstands the av. winter conditions, and that it is better to allow it to stand until it can be cut rather than to windrow. In the warm weather of early harvest the time from cutting to grinding should not exceed 4 days. When the cane has been frosted there is no appreciable loss 10 days after cutting. Cane

burnt standing did not deteriorate rapidly during cool weather. No expts. were made with burnt cane in warm weather. J. F. BREWSTER

Experiments in the harvesting of burned cane. H. H. DODDS AND P. FOWLIE. *Planter and Sugar Mfr.* **81**, 184–5(1928); *Facts About Sugar* **23**, 594–5(1928).—Cane left standing after burning suffers no deterioration for 9 days but thereafter shows slow, gradual diminution in sucrose and purity. With hand-trashed cane deterioration sets in at a uniform rate from the time of harvest. The above are exptl. results obtained in Natal. J. F. BREWSTER

Revolving knives and shredders. FRANCIS MAXWELL. *Facts About Sugar* **23**, 90–1(1928).—Summarizing, M. states that (1) where cane is mechanically unloaded to the carrier, knives and shredders are used in supplementary combination. (2) Either 1 or 2 sets of knives may be used, but for levelling purposes only to prep. the cane for the crusher. (3) A shredder of modern type is essential to achieve economically the max. extn. by the milling plant. (4) When cane is loaded on the carrier in regular layers by hand, the advantages gained from levelling by knives are not balanced by the gain in capacity. J. F. BREWSTER

Revolving knives and shredders in the cane sugar mill. THEO. NICHELSEN. *Planter and Sugar Mfr.* **80**, 22–3(1928).—N. discusses the value of knives in prepg. cane for the mill and the effect of shredding upon extn. in the Philippines. J. F. B.

The cold water treatment. T. E. HOLLOWAY. *Facts About Sugar* **23**, 907(1928).—H. acknowledges the priority of Cleare in recommending this method of treating seed cane. M. J. PROFFITT

The dilution problem. E. M. COPP. *Facts About Sugar* **23**, 280–4(1928).—**Bagasse and maceration per cent cane.** *Ibid* 326–9.—These 2 articles bear upon sugar house control calcns. J. F. BREWSTER

A maceration efficiency factor. E. M. COPP. *Facts About Sugar* **23**, 350–1 (1928); cf. preceding abstracts.—The efficiency of admixt. of maceration water is discussed from the standpoint of replacement of residual juice in the fiber by water. The *maceration efficiency factor* = [(100 − fiber in bagasse)/(100 × fiber in bagasse)] × [1 − (diln. % cane)/maceration % cane)]. J. F. BREWSTER

The removal of gums from cane juices. MAURICE BIRD. *Facts About Sugar* **23**, 139(1928); *Planter and Sugar Mfr.* **80**, 143–4; cf. *C. A.* **22**, 2679.—Comparative data are given on treatment of juices by "superheat" (115°), followed by liming, by cold liming in the usual way, and by treatment with Na_2HPO_4 followed by liming in the usual manner. The gums were detd. by pptn. with alc. as usual. Apparently more gums are removed by the "superheat" combined with Na_2HPO_4 treatment, but some are already removed by heat alone. The "superheat" treatment on a large scale over a no. of years has given excellent results in raw sugar manuf. J. F. BREWSTER

The ratios of ash constituents in different cane varieties. C. E. COATES, E. A. FIEGER AND L. G. SALAZAR. *Planter and Sugar Mfr.* **80**, 421–2(1928)—Four varieties of Louisiana sugar canes were analyzed for moisture, ash, N and ash constituents. The results are tabulated. Tables are given showing content of K_2O and P_2O_5 as % ash and as % dry wt., also ratios of sugar to K_2O and to P_2O_5 in dry matter. J. F. BREWSTER

Moist storage of commercial sugar beets. JEAN A. PACK. *Facts About Sugar* **23**, 378–9(1928).—To reduce the sugar loss of com. beets to a practical min., the beets should retain their normal wt. throughout the storage period. Field piles, silos, rapid transportation, large piles, etc., are of value insofar as they help to maintain the normal moisture requirements. The fundamental importance of moist storage should be recognized. J. F. BREWSTER

The present state of the problem of beet drying. K. ŠANDERA. *Listy Cukrovar.* **47**, 1–6(1928).—A review. FRANK MARESH

Cost of drying beet cossettes. ANON. *Facts About Sugar* **23**, 830–1(1928).—An advanced abstract of a report to be published by the Inst. Eng. of Oxford Univ. The cost of producing a ton of sugar by the Oxford modification of the De Vecchis process in the Eynsham factory with a capacity of 25,000 tons annually (105 days drying cossettes and 224 days extg. the dried cossettes) has been found to be £7 18s 3.98d; in a self-contained factory of 100,000 tons capacity annually, it is computed that the cost per ton should be but £3 18s 3d, and for an organism of drying stations supplying a large factory the cost should be still less. Capital charges are not indicated as included. M. J. PROFFITT

Desiccation of sugar beet and the extraction of sugar. B. J. OWEN. *Rept. Ministry Agr.* **1927**, 84 pp.—A full report is given of an investigation into the De Vecchis process (*C. A.* **18**, 1761) carried out at Eynsham. The conditions necessary for drying

beet cossettes were examd., first in lab. expts. and then in 3 types of driers, *viz.*, (*a*) a cylindrical mass drier similar in principle to that of Brit. 235,273; (*b*) a moving-belt drier of the type used by De Vecchis, and (*c*) a tray drier with 3 hot-air compartments, one perforated tray with cossettes being placed over the 1st, another over the 2nd and 2 over the 3rd, these positions representing successive stages of drying. Among the factors studied were the practicable thickness of the cossette layer (8–12 in.), the reduction in bulk (about 50%) and in resistance to air during drying, and the varying sensitiveness of the sugar to high temps. at different stages of drying. It was completely established that the drying can be carried out on a large scale without inversion of sugar or caramelization. So long as the cossettes were moist the temp. of the applied air (38–127°) had no effect on the sugar, but loss of sugar occurred from the use of high temps. (above 113°) on cossettes having a moisture content below 20%. It was accordingly considered inadvisable to continue heating after the moisture was expelled, no benefit being found to result from the prolonged heating advocated by De Vecchis for the coagulation of proteins. The drying process could thus be completed in less than 1 hr. The tray drier was adopted for most of the work as being easy to manipulate and control. Cossettes containing 3–5% of moisture suffered no deterioration on storage; after long exposure to the air the moisture content rose to 11–13%, but not beyond, and in large piles only the outermost layers of cossettes (to a depth of about 6 in.) lost their original crispness. Extn. of the dried cossettes in a battery of small diffusion vessels, each provided with a calorisator for heating the juice passing from one vessel to the next, yielded juices of 45–50° Brix with purities of about 90%. These thick juices had excellent phys. characteristics, being light in color and clear, and not darkening perceptibly on exposure to air. The difficulty experienced in obtaining gravities above 50° Brix, together with microscopical evidence and osmotic expts., led to the conclusion that the cells of the beets are not ruptured by the drying process, and that the subsequent extn. of the sugar is an osmotic phenomenon as in the case of fresh beets. A continuous diffuser in the form of a vertical cylinder with a helical conveyor to raise the cossettes against the descending juice (cf. *C. A.* **21**, 2198) was also used successfully for the extn. of the sugar. Serious filtration difficulties were experienced with De Vecchis' method of purifying the juice with lime and superphosphate. Satisfactory working was attained, however, by a mech. removal of suspended impurities in a centrifugal clarifier, either before or after liming, the ppt. produced by superphosphate being then easily filterable. The color of the purified juice can, if necessary, be further improved by treatment with active carbons. Without the latter treatment, however, a strike of white sugar could be obtained from the juice reinforced by a proportion of second-product sugar. The amt. of effluent from flumes and beet washing is, of course, the same for the desiccation process as for the diffusion process, but that from the working of the cossettes is less for the former than the latter, and would in a normal desiccation factory be distributed over a long working period. An appendix dealing with beet-factory effluents describes a revolving double screen by which the coarse and finer suspended matters can be separately removed from the waste waters from flumes and washers, and some suggestions are made for the treatment of process affluent. B. C. A.

Natural alkalinity [of beet juices]. O. Spengler and C. Brendel. *Z. Ver. deut. Zucker-Ind.* **1927**, 801–16.—By the natural alky. of beet juice is understood the residual alky. after treatment with lime and pptn. of this by CO_2; it represents free potash and soda originally present as salts. The greater part of the alkali metals in fresh juice from sound beets is combined with acids which are precipitable by lime. In carbonatation, therefore, it is not necessary to leave any free lime to supply the requisite final alky., the liberated potash and soda sufficing for this. These are present as hydroxides at the end of the first carbonatation, and should be converted into carbonates, but not into bicarbonates, by the second. In old or damaged beets the alkali metals are combined with acids which are not precipitable by lime, and they remain as neutral salts after carbonatation, so that there is a deficiency of natural alky., and it becomes necessary to leave some free lime after carbonatation to obtain the necessary final alky. To avoid this, since lime alky. is particularly undesirable during evapn., a suitable amt. of Na_2CO_3 may be added to the juice, *e. g.*, before the final carbonatation. As a guide in ascertaining how much to add, the authors describe methods for detg. the "theoretical" and the "practical" residual alky. on filtered juice from the first carbonatation. The "theoretical" residual affinity is the excess of the total alky. (to phenolphthalein) over the lime content (detd. by soap soln.), both being expressed as CaO. Probably, however, the "practical" residual alky. will afford a closer estimate of the condition of the juice after the final carbonatation. It is found by neutralizing

to phenolphthalein with 0.2*N* HCl, then adding an equal vol. of 0.2*N* Na_2CO_3, heating in boiling water, filtering from $CaCO_3$, cooling, and detg. the residual alky. with 0.0357*N* HCl. Full working details and precautions are given. Factory experience alone can decide which of these methods is the more useful. B. C. A.

Removal of phosphoric acid from beet juice during liming and saturation. O. Spengler and A. Traegel. *Z. Ver. deut. Zucker-Ind.* **1928,** No. 859, 190-8.—In a certain beet sugar factory, the sight glasses of the evaporators were rapidly fogged, transparency being lost within a few hrs. after cleaning. This condition was very irregular and had not been observed in the past 20 years. Analysis showed that the hard deposit consisted of about 65% $Ca_3(PO_4)_2$, the remainder being $CaCO_3$. In only one factory were these high phosphate deposits found, that factory using H_3PO_4 in the battery to overcome other troubles. H_3PO_4 is always present in beet juice. *Conclusions:* (1) The sepn. of H_3PO_4 during clarification is greater with increased use of lime. While Pachlopnik (*C. A.* 20, 2592) obtained complete removal of phosphoric acid in sugar solns. by treatment with 3.3% CaO, the authors pptd. 98.4%, 96.1% and 94.8% of the phosphoric acid by the use of 3%, 2% and 1.5% CaO, resp. (2) During satn. a part of the H_3PO_4 remaining in soln. is carried down by the $CaCO_3$ ppt. (3) The degree of satn. influences the quantity of H_3PO_4 remaining in or going into soln. again. (4) Satn. to an alky. of 0.018 to 0.01% CaO is most favorable for the removal of the H_3PO_4. With juice treated with 2.5% CaO and satd. to an alky. of 0.018% CaO only 0.3% of the H_3PO_4 originally present in the diffusion juice remains in soln. (5) On further satn. or supersatn., H_3PO_4 is again dissolved. E. A. Fieger

Surface tension and adsorbents. J. Dědek and J. Nováček. *Sugar* **30,** 99-101, 149-51, 199-200, 247-8(1928).—Detns. of surface tension and viscosity measurements were made on all products of beet sugar factories from diffusion juices to finished sugars and molasses and the results are shown in tables and graphs. The influence of carbonation, sulfitation and treatment with decolorizing carbon are followed through the factory and the action of electrolytes, p_H, and impurities upon the surface tension of sugar liquors is discussed. J. F. Brewster

The disposal of effluents from sugar-beet factories. A. J. V. Underwood. *Ind. Chemist* **3,** 260-7(1927); *Pub. Health Repts.* **43,** 2354(1928).—The manuf. of beet sugar is limited to about 3 months of the yr. and a heavier charge is thus thrown on the cost of production for a given capital expenditure than is the case in industries which are employed throughout the year. This consideration assumes especial importance in view of the large quantities of H_2O used and waste produced in the manuf. of beet sugar. The location of beet-sugar factories in agricultural districts and on streams of comparative purity renders any contamination of the stream more noticeable and more significant than that which has already reached a high degree of pollution. During the early part of the period for which the sugar factory is working, the flow of many streams is low, and this may require greater storage facilities for the effluent or a higher degree of purity. The lower temps. at this time of the yr. also affect adversely the activity of bacteria and the efficiency of biological methods of purification. In extreme cases, where a stream is frozen over, further difficulties are introduced, since it has been shown that in such cases the dissolved O content of an unpolluted stream may fall to as low as 40% of satn. Four different wastes are produced by beet-sugar factories. Beet carrying and washing H_2O, amounting to about 2 m. g. d. per 1000 tons of beets treated daily, is the least objectionable, contg. some suspended mineral matter and ordinarily but 20 to 50 p. p. m. sugar, and having an O consuming value of about 340 p. p. m. This is treated successfully by plain sedimentation for 6 to 8 hrs. and by pptn. with lime. Diffuser battery and pulp press waters, together amounting to 300,000 g. p. d. per 1000 tons of beets, are more objectionable and more difficult to treat. Combined, these carry 0.6% of sugar and an equal amt. of other org. matter. Among methods used with some success in treating these are: addn. of lime, followed by carbonation, with or without the mixing in of beet carrying and washing H_2O; plain sedimentation and land irrigation; septic tanks with or without the use of lime; contact beds; trickling filters; fermentation with or without lime to neutralize the butyric acid formed; and activated sludge. Each process has definite limitations. Filter-press lime sludge is readily disposed of by application to land, preferably treated previously with quicklime. Steffens waste water, the production of which is limited to the United States, is quite objectionable, having an O-consuming power of 3000 p. p. m. and containing all the mineral salts of the beets which may be toxic to fish. C. R. Fellers

Sugaring out of molasses in the American beet-sugar industry. Emanuel Šlechta. *Chem. Obzor* **2,** 259-62; *Chem. Zentr.* **1927,** II, 2478.—Processes ordinarily used in America for the recovery of sugar from molasses are discussed, with special reference

to the plant of the Great Western Sugar Co. which uses the new baryta process.
C. C. Davis

A loader for sugar beets and loose materials. Ladislav Rychetský. *Listy Cukrovar.* **46,** 566–8(1928). A description and tables comparing costs of operating with hand labor and loader. Frank Maresh.

The composition of German molasses during the season of 1926–1927. Drews. *Z. Spiritusind.* **51,** 96(1928).—Analyses of molasses are given. C. N. Frey

Extraction of sucrose from carobs. Guiseppe Oddo. Univ. de Palerme. *Chimie et industrie* **20,** 207–15(1928); cf. *C. A.* **22,** 2285.—A discussion of the economic advantages of the production of sucrose from carobs, as compared with sugar cane and beets. All attempts to produce sucrose from carobs by diffusion or extn. with H_2O have failed; but it readily crystallizes from the EtOH or MeOH ext., and this process is proposed for its com. manuf. A. Papineau-Couture

The saccharification of wood waste. E. Hägglund. *Papierfabr.* **25,** Tech.-Wiss. Teil 52–60(1927).—An address covering the historical aspects of cellulose saccharification. A com. plant for the utilization of wood waste by the patented Goldschmidt process is described. J. L. Parsons

The ternary system: strontium oxide-sucrose-water. W. Reinders and A. Klinkenberg. Tech. Hochschule, Delft. *Z. Elektrochem.* **34,** 406–7(1928).—A criticism of the article by Grube and Nussbaum (cf. *C. A.* **22,** 1870). R. and K. take exception to G. and N.'s paper on 3 points: (1) The soly. of $Sr(OH)_2.8H_2O$ is raised by addn. of sugar instead of lowered as G. and N. assert. (2) According to G. and N.'s figures the compn. of the soln. in equil. at 100° with $Sr(OH)_2.8H_2O$ and sucrose is 21% SrO and 11% sugar. R. and K. find the triple point of the system $Sr(OH)_2$-disaccharide-soln. at 70° and with 0.1% sugar in soln. (3) G. and N. find the soly. of sugar greatly decreased by the addn. of small quantities of SrO. R. and K. find that addn. of SrO raises the soly. of sugar very slightly. A full account of the work is promised. R. E. Gibson

The utilization of bagasse in the production of alcohol. I. II. Henry Arnstein. *Planter and Sugar Mfr.* **81,** 121–4, 143–4(1928).—A review is given of the prepn. of fermentable sugars and alc. from cellulose material and similar expts. of A. on bagasse fiber. J. F. Brewster

Tests with a new mechanical bagasse stoker. I. Hes and H. J. Spoelstra. *Arch. Suikerind.* **36,** III; *Mededeel. Proefsta. Java-Suikerind.* 821–42(1928).—A new bagasse stoker, installed at the Gayam mill (Java), and in full operation, is described and illustrated. The results are satisfactory, little attention is required, and the combustion is improved. P. R. Pekelharing

Electrometric determination of the ash of sugar-factory products. O. Spengler and F. Tödt. *Z. Ver. deut. Zucker-Ind.* **1928,** 1–12.—Electrometric ash detns. on raw sugars are best made on solns. of 5° Brix, for although errors due to small variations in sugar concn. are least in solns. of about 30° Brix, the results obtained at this concn. are liable to deviate much more widely from the results by incineration than those obtained with 5% solns., the conds. of the individual salts present being affected to different extents by high concns. of sugar. In general, the influence of the cond. of the water used is depressed in the presence of the sugar and its salts. Zerban and Sattler (*C. A.* **21,** 2394) found that water of very low cond., 3×10^{-6}, exerted its full influence, but water of cond. 40×10^{-6} contributed only 27.4×10^{-6} to the cond. of 5% raw cane-sugar solns. The factor C representing the ratio between cond. and ash content (by incineration) was found by Zerban and Sattler to range from 1476 to 2022 for cane sugars of various origin in 5% solns. For sugars from the same district it was fairly const., being 1786 on the av. for Cuban, and 1560 for British West Indian sugars. For 50 raw beet sugars tested by Kayser (*C. A.* **21,** 1560) it ranged from 1680 to 1880. According to Lundén (*C. A.* **21,** 2569) it is lower for beet factory products than for refinery (*i. e.*, affined) beet products; and, in general, as the authors have confirmed, there is an inverse relation between C and the quality of beet products. A high value of C is assocd. with a high ratio of org. to inorg. salts, which indicates inferior quality. For raw cane sugars Zerban and Sattler found that if k is the sp. cond. of a filtered soln. contg. 10 g. of sample in 200 cc., and k_1 that for a similar soln. contg. also 5 cc. of 0.25 N HCl, the ash content is given by the formula: $0.0001757(9.13k + 1935 - k_1)$. The results show much more uniform agreement with incineration results than when a single electrometric factor is used. By this formula variations in the amt. of org. salts present are largely compensated, since they correspondingly lessen the value of k_1 by the replacement of part of the added mineral acid by feebly dissocd. org. acids.
B. C. A.

Sugar-ash bridge. Anon. *J. Sci. Instruments* **5**, No. 9, 296–7(1928).—Announcement of the new Leeds & Northrup a. c. wheatstone bridge for the detn. of the sol. ash of sugar or sugar products together with directions for its use. Current of com. frequencies is used. J. H. Perry

Adsorption in thick juice by layers of carbon. T. Dědek and B. Tumova. *Z. Zuckerind. cechoslov. Rep.* **52**, 65–75(1927).—Beet thick juice and melted raw beet sugar were filtered through layers of various thickness of washed and dried carboraffin, Norit and powd. bone char. Degree of adsorption of color, N, CaO and sulfate ash, and their reversibility as expressed by their occurrence in sweet water, were detd. from analysis of original and treated liquors, chars and the sweet waters. The retention power is highest for color: carboraffin, followed by Norit and bone char. For N: Norit, carboraffin, bone char. For CaO: bone char, carboraffin, Norit. For ash the data are inconclusive. The coloring matter of raw sugar is more easily adsorbed than that of thick juice, probably because of a change in dispersion due to addnl. boiling. As filtration progresses the gradual displacement of matter already adsorbed takes place. On account of the uneven permeability of the layer a study of the adsorption laws could not be undertaken. Slowing down the rate of flow during filtration becomes the greater the thicker is the layer of char. F. R. Bachler

The extraction of anhydrous molasses with organic solvents. R. Vyskočil. *Z. Zuckerind. cechoslov. Rep.* **52**, 77–88, 89–98(1927).—Desugarization of beet molasses with 11 different org. solvents, and rate of removal of nitrogenous matter and other nonsugars were studied with molasses that was dehydrated on strips of filter paper. Figures refer to % substance in original molasses. *AcOH* removed nearly all color, ash and N. Recovered: 41.6 of Clerget sugar of 86.5 true purity. *MeOH* removed 25.26 ash, 56.91 total N, 79.50 betaine N, 20.85 color. Recovered: 81.23 Clerget sugar of 74.08 true purity. *Alc.* removed 41.03 ash, 61.1 total N, 75.83 betaine N, 13.23 color. Recovered: 84.71 Clerget sugar of 72.18 true purity. *Am alc.* recovered, depending on time, temp. and moisture in molasses, 0.91–3.93 dry substance, little more than $^1/_2$ of which is betaine N, representing $^1/_4$ of total betaine N of original molasses. *Et_2O* removed 0.23 dry substance consisting principally of fat. *Acetone*, cold, removed 0.65, hot 1.43 dry substance with 0.24 fat. *Chloroform* removed 0.21 dry substance contg. 3.12 ash, 1–12 N, and the rest fats and soaps. *Benzene* removed 0.25% dry substance, principally fat. *Aniline* was practically inert. *Phenol*, anhydrous, removed from anhydrous molasses 69.75 ash, 88.67 total N, 95.92 betaine N, 27.46 color. Recovered: 44.65 Clerget sugar of 69.4 true purity. Phenol, satd. with H_2O, removed from wet molasses 82.85 ash, 93.45 total N, 98.08 betaine N, 70.35 color. Recovered: 22.98 Clerget sugar of 78.91 true purity. *Pyridine* removed 2.42 dry substance with only 0.36 total N and 0.21 betaine N. It is intended to apply phenol as a means for the isolation of betaine. Former expts. with anhydrous molasses on strips of filter paper were repeated with wet molasses and the most promising solvents and mixts. thereof. Figures refer to % substance in original molasses. 180 g. mol. + 500 cc. MeOH, $^1/_2$ hr. with stirring, went into soln. The insol. residue was 4.68% on dry substance with 25% of original color. 150 g. mol. + 500 cc. 96% EtOH, 1 hr. with stirring, extd. 20.28 dry substance, 15.04 Clerget sugar of 47.91 purity, 14.7 ash, 32.19 total N, 45.22 betaine N, 8.66 color. Residue: 84.96 Clerget sugar of 68.63 purity. 170 g. mol. + 360 cc. AmOH extd. 0.41 dry substance, 0.19 sugar, 0.28 ash, 2.79 total N, 2.28 betaine N. With increasing mol. wt. of alc. soly. of mol. constituents falls, but extn. of N rises. 168 g. mol. + 500 cc. acetone in 3 hrs., removed 1.16 total N. 500 g. mol. + 500 g. phenol after 1 week gave a lower layer contg. many large, dark sugar crystals and sirup contg. 61.21 Clerget sugar of 63.38 purity and an upper layer consisting of phenol ext. contg. 40.61 dry substance, 38.79 Clerget sugar of 63.39 purity, 49.88 ash, 60.12 total N, 67.35 betaine N, 31.20 color. Isolation of betaine with HCl and freezing failed. Sugar crystals freed from phenol with benzene had 93.02 direct polarization, 91.99 Clerget polarization, 1.67 ash, 0.20 total N. Benzene-AcOH mixt. yielded 65% nearly white sugar of 98.79 direct and 97.61 Clerget polarization, 0.25 ash, 0.03 total N. Phenol-AcOH mixt. gave 55% nearly white sugar of 98.43 polarization, 0.01 ash. One kg. mol. + 1.5 l. H_2O + 1.5 kg. phenol gave an ext. contg. 10.55 Clerget sugar of 32.31 purity, 13.15 ash, 72.6 total N, 97.68 betaine N and a residue contg. 89.45 Clerget sugar of 73.41 purity, which later yielded 18.46 raw sugar of 95.85 polarization and 1.14 ash. From the phenol ext. betaine was isolated, yielding 32.1%. F. R. Bachler

Activated carbons in sugar manufacture. Jaroslav Dědek. *Sugar* **30**, 51–2 (1928).—The employment of decolorizing carbons either in layers or in suspension is discussed. The long layer of bonechar usually employed is necessary because this

C is not of high initial decolorizing capacity. When working in suspension normally the C is used for each liquid only once so that the resulting adsorption equil. corresponds to a single use on the darker soln. The exhaustion of a C in layers may be brought about, however, by repeated use on new liquors. If, as is usual in practice, gradually darker solns. be decolorized, the final exhaustion of the C used in suspension or in layers is practically the same, *i. e.*, very nearly the theoretical max. A graph is given showing the exhaustion produced by solns. of different degrees of coloration. J. F. B.

Estimation of the value of activated carbons. JAROSLAV DĚDEK. *Sugar* 29, 255–6, 307–9(1927); *Intern. Sugar J.* 29, 446–7(1928).—Adsorption is considered from the theoretical standpoint. Invisible adsorption, that which cannot be estd. by the colorimeter, is considered often greater and more important than decolorization. The adsorption equil. must take place between the concn. of the solute on the surface of the adsorbent and the concn. left in soln. which equil. can be represented by the adsorption isotherm. In a graph given, degrees Stammer, left in soln., are plotted as abscissas, and the quantities retained by the C, in so-called Fusca degrees, as ordinates. The isotherm is found by decolorizing a soln. with increasing quantities of C and it enables one to solve questions and elucidate laws of adsorption, such as, for instance, that a C on contact with a dil. soln. cannot retain as much coloring matter as it does from a concd. one. J. F. BREWSTER

A method for determining the decolorizing power and an analysis of bone charcoal. R. PROCHÁZKA. *Listy Cukrovar.* 47, 14–5(1928).—Into a tin digestion flask are placed 100 g. of the clarifying agent and 400 g. of a soln. of known color value and sp. gr. The mixt. is immersed in a 90° water bath for 15 min. with frequent stirring; it is filtered warm with a small quantity of kieselguhr. The sp. gr. and color value are detd. as before. The method prevents caramelization and is used in regeneration studies. Routine tests for CaS and $CaSO_4$ are insignificant. Org. matter is extd. in warm NaOH; the soln. should remain clear. For P_2O_5, 5 g. bone charcoal are ignited in a Pt crucible in an elec. furnace. The residue is dissolved in a H_2SO_4 and HNO_3 mixt. NH_4 citrate soln. is added, and the mixt. is kept cool. The ppt. is washed free of Cl, dried, ignited and weighed as P_2O_5. The first ignition insures a pure ppt. FRANK MARESH

The examination of starch and its derivatives. F. L. P. KRIZKOVSKY. *Melliand Textilber.* 9, 594–6, 766–8(1928).—A compilation of methods for the phys. and chem. examn. of starches, dextrins, etc. E. R. CLARK

Studies on plant colloids. XX. Behavior of starch sols in the dark field. M. SAMEC. *Biochem. Z.* 195, 40–71(1928).—As the starch sol ages the Brownian movement of the ultramicrons ceases first, and is followed by vibration and finally complete rest. The particles aggregate and after a certain interval there are no more free ultramicrons. Two types of aggregation can be observed: spheroidal and string-like, the former occurring in sols with a blue I_2 reaction and the latter with the red reaction. The ultrafiltrate contains a very much smaller number of visible particles which are likewise much smaller than in the original sol. The differences between wheat and potato starches are only quant. Even Lintner's dextrin and starch peptized by means of ultra-violet rays can still be observed ultramicroscopically, showing the presence of typical ultramicroscopical forms. Boiling causes a reduction in the number of visible particles. Their movement is lost but the typical aggregation forms remain. Min. traces of P_2O_5 appear always to exert a stabilizing action on the starch. **XXI. The distribution of phosphorus and nitrogen within the starch grain.** *Ibid* 72–8(1928).—The sepn. of the concentric layers of the starch grain shows that the most outside portions are richest in N and P. The amylocelluloses of wheat and of corn starch grains are particularly rich in both these elements and contain besides SiO_2. The amylocellulose from potato can be prepd. N-free. The removal of SiO_2 from the starch grain does not alter the yield of amylocellulose. S. MORGULIS

The manufacture of corn starch, the utilization of the residue and the recovery of corn oil. O. K. A. KRIZKOVSKY. *Chem.-Ztg.* 52, 526–8(1928).—A description including the flow diagram. A. L. HENNE

The yield of potato starch works. B. ELEMA. Coop. Aardappelmeel Verkoopbureau, Veendam. *Chem. Weekblad* 25, 498(1928).—The best modern yield figure of potato starch is up to 11.7 kg. per hectoliter (61 kg. potatoes of sp. gr. 1.087 with 16.2% starch). The theoretical yield is 12.35 kg. B. J. C. VAN DER HOEVEN

Treating sewage and other waste products [from sugar factories] (Brit. pat. 284,267) 14. Recovery of N and acetone from molasses, etc. (Fr. pat. 635,915) 16. Apparatus for dissolving sugar, etc. (Fr. pat. 635,285) 1. Countercurrent filtration system for sugar (U. S. pat. 1,686,092) 13.

Drying sliced sugar beets, etc. B. J. OWEN. Brit. 285,115, Nov. 5, 1926. Various details of temps., air pressures and current velocities, etc., are specified.

Filtering sugar juices supplied as jets to a rapidly vibrating inclined screen. FRANK L. ALLEN. U. S. 1,685,621, Sept. 25. This treatment prevents obstruction of the screen by bagacillo.

Apparatus for drying sugar crystals. PAUL TUGAULT. Fr. 635,429, June 2, 1927. The sugar falls against a series of baffles and meets an ascending current of warm air. The sugar dust is extd. from the air by passing it through a centrifuge against the sides of which a fine spray of water is directed.

Grape sugar and dextrin. A. A. SCHMIDT (SHMIDT). Russ. 4545, Sept. 15, 1924. Solns. of fruit skins or pulp in concd. H_2SO_4 obtained by known methods are dialyzed before the final hydrolysis at high temps. to obtain highly concd. solns. of dextrin at a low concn. of the acid.

Recovering sucrose from mixtures containing reducing sugars. HENRY W. DAHLBERG. U. S. 1,686,440, Oct. 2. Materials such as mixed molasses and concd. "sweet water" of sugar refinery operation are regulated so that the ratio of sucrose to reducing sugar will be at least 2.8:1 and the sucrose is pptd. by treating the mixt. with $Ba(OH)_2$ or other alk. earth hydroxide to form a saccharate; the saccharate is then sepd. into an alk. earth metal compd. and sugar sirup by use of CO_2.

Sugar recovery from muds. ROBERT C. CAMPBELL (to United Filters Corp.). U. S. 1,685,118, Sept. 25. Muds sepd. from sugar juices are continuously filtered and the cloudy portion of the filtrate is continuously returned to a previous point in the process; any remaining portion of the filtrate is continuously collected and the filter cake is continuously washed and the wash water collected. An app. is described, the filter surface of which is completely cleaned at each cycle of the filter operation.

Sugar from wood, peat and moss. A. E. MOZER. Russ. 3714, Sept. 14, 1924. The materials are treated with dil. acids below 120° with a continuous agitation of the mass, and the insol. material is sepd. from the sugar soln. obtained, which is used again to decrease the amount of acid and fuel used and to obtain a higher concn. of the sugar soln.

Horizontal rotary drum mixing apparatus suitable for use in sugar manufacture. SCHNEIDER ET CIE and AKCIOVA SPOLECNOST DRIVE SKODOVY Z'AVODY V PLZNI. Brit. 284,954, Sept. 8, 1927. The drum is provided with a water jacket having baffled compartments. Various structural details are specified.

Purifying sugar solutions. KARL KOMERS and KARL CUKER. Fr. 635,624, June 8, 1927. See Brit. 283,564 (*C. A.* **22**, 4269).

Betaine hydrochloride. DONALD K. TRESSLER (to Larrowe Construction Co.). U. S. 1,685,758, Sept. 25. Concd. residual liquors of beet molasses are treated with an inorg. acid such as H_2SO_4, H_3PO_4 or HCl and with a sol. chloride such as $CaCl_2$ to obtain betaine-HCl which is sepd. from KCl and NaCl by use of MeOH.

ALLEN ROGERS

Unhairing with mold enzymes; preliminary investigations and industrial application. G. Abt. *Chimie et industrie* Special No., 716–21 (April, 1928).—See *C. A.* **22,** 1056. A. Papineau-Couture

Contribution to the study of tanniferous barks of Madagascar. F. Heim de Balsac and A. Deforge. Station Biol. d'Auteuil-Boulogne. *Chimie et industrie* Special No., 728–31 (April, 1928).—See *C. A.* **22,** 1055. A. Papineau-Couture

Hide powder provision. Tatarskii. *Collegium* **1928,** 463–4. Hide powder comparing favorably with English powder was prepd. as follows: Hides were limed and delimed as usual, bated with Oropon and then treated for about 4 days with NaOH. After washing, they were brought to the isoelec. point (p_H 5) with acid, washed again, dried with alc. and ground in a cooled mill. I. D. C.

Some problems of fat liquoring. Wilhelm Schindler. *Collegium* **1928,** 241–74. The factors influencing stability of emulsions are reviewed. The viscosity of some sulfonated oil emulsions was measured with Ostwald-Auerbachs viscometer (*C. A.* **21,** 3506). "Structural" viscosity was observed below 45° in alkaline (p_H 9) but not in acid (p_H 6) solns. Several sulfonated oils were fractionated according to the following scheme: 5 g. of oil was shaken first with 25 cc. of 96% EtOH, next with 15 cc. EtOH and 5 cc. *N* alcoholic KOH, then with EtOH until the EtOH was colorless. The residue (**c**) was usually a thick, bright yellow to orange-brown oil. The EtOH ext., **a** and **b,** (its vol. should be about 100 cc.) was shaken with 10 cc. H_2O, 5 cc. glacial acetic acid and 25 cc. petroleum ether, then twice with petroleum ether alone. The petroleum ether ext. was washed with 70% EtOH. The EtOH residue (**b**) was a dark brown, sirup-like product which contained the sulfonated oil. The petroleum ether ext. (**a**) was sepd. into 2 portions (a_1 and a_2) by shaking with 10 cc. *N* alcoholic KOH and 10 cc. of 70% EtOH. The petroleum ether residue (a_1) consisted of neutral fats, the alc. residue (a_2) of free fatty acids and oxy fatty acids. **b** contains the emulsifier. a_1 and **c** are neutral and so are not emulsifiers but are valuable lubricants because of their high viscosity. a_2 should be as small as possible. Pieces of chrome leather were fat liquored with soap, sulfonated oil or emulsions of these with mineral oil. The velocity of fat absorption and the quantity of fat absorbed depended on the kind of emulsifier, the drop or particle size, the temp. and the diln. of the liquor. The velocity was increased by mineral oil or fat, or by a change in p_H causing an increase in drop size. It was greatest at the beginning of the absorption. Soap solns. or soap and mineral oil emulsions were absorbed more slowly and less completely than emulsions based on sulfonated oils. More fat was absorbed from clear sulfonated oil solns. than from soap solns. I. D. Clarke

The physico-chemical nature of tannin and nontannin. P. Yakimov. *Collegium* **1928,** 426.—Temp. and degree of division of the material influence the soly. of tannin greatly but that of nontannin very little. Boiling tannin exts. caused little or no loss of tannin (except 40% loss with badan) while extn. with boiling H_2O gave results 30% to 40% lower with a corresponding increase in nontannin. The pectins produced by hydrolysis of other plant substances may combine with and ppt. tannin. Freezing increases the concn. and purity of tannin exts. Tannin and nontannin can be sepd. by dialysis because the latter is cryst. and the tannin colloidal. Dialysis at a low temp. (4°) is best because there is then almost no loss of tannin. The cell walls of the material can act as membranes. The degree of division is then a factor since grinding destroys some of the cell wall membranes. With the above principles exts. richer in tannin have been prepd. I. D. Clarke

The colorimetric determination of hydrogen-ion concentrations (p_H values) in the tannery. L. Köhler. *Collegium* **1928,** 449–53.—A colorimetric spot method for detg. the p_H of colored solns. is described. Color charts and a porcelain plate are used. The color should be observed in a thin layer of the soln.; at the edge of highly colored solns. the indicator tint is easily observed. To have as high a concn. of indicator as possible one drop of indicator is placed on the plate and then the soln. to be measured is added drop by drop until the tint no longer changes. I. D. Clarke

The Darmstadter apparatus for tannin analysis. E. Stiasny. *Collegium* **1928,** 383–8; cf. *C. A.* **22,** 2076.—A vessel somewhat similar to that of Jamet (*C. A.* **19,** 417) is described. It consists of a glass cylinder, 55 × 150 mm., with a glass filter plate sealed in one end. Metal caps fitted with soft rubber washers are screwed onto each end. It is used for shaking hide powder with the chroming or tannin ext. soln., then the soln. is removed by setting the filter end into a suction filter funnel and applying

suction. H_2O in the hide powder is adjusted by weighing the entire vessel (wt. empty about 180 g.). I. D. CLARKE

The new procedure for tannin determinations. JOH. PAESSLER. *Collegium* **1928,** 352–61.—Comparison was made of filter candles and filter papers S & S no. 590 and no. 605 for detg. sol. solids. Paper no. 605, extra hard, gave lower results (0 to 4.5%) than the candles. Paper no. 590 gave about the same or slightly lower results than the candle but with some exts. perfectly clear filtrates could not be obtained. Also filtration with paper requires much more time than with candles. Tannin exts. were prepd. by the old and the new (International) methods, then analyzed. Since the results were nearly the same the old method is preferable for it requires much less time. A vessel for washing the hide powder and detannizing the ext. is described. It consists of a cylindrical glass vessel with a conical bottom, and closed with a rubber stopper. A tube with a small Berkefeld filter at the end is inserted in the vessel to remove by suction either wash water or nontannin soln. I. D. CLARKE

Chrome tanning. VIII. Salts of chrome with formic acid and their tanning action. E. STIASNY AND G. WALTHER. *Collegium* **1928,** 389–425; cf. *C. A.* **20,** 3314.—Hexaquochromeformate, $[Cr(H_2O)_6](HCOO)_3$, I was prepd. by Werner's method. It is a gray-violet cryst. salt, slightly sol. in H_2O, which on standing changes to violet, then to green. This change is caused by hydrolysis to monohydroxopentachromeformate, $[Cr(OH)(H_2O)_5](HCOO)_2$, and formic acid; the dihydroxo salt does not form. On further aging the green soln. again becomes violet because the formate radical enters the Cr complex. In dil. soln. a complex is formed of 3 Cr to 3–3.5 formate radicals; in concd. soln. there is slowly formed the green hexaformatodihydroxychromeformate, $[Cr_3(OH)_2(HCOO)_6]HCOO.5H_2O$, II, which does not contain formato groups but formato bridges and so is more stable to alkali than the violet form. Addn. of alkali to concd. solns. of I does not lead to formation of II but to anodic violet complexes. II is not as stable, especially in dil. solns., as would be expected from its spontaneous formation from I or from hexaformatosodium chromate, III. On heating solns. of I or II the greater part of the formic acid is split off; there results nondialyzing complexes, which are not affected by HCl or NaOH and which contain many "ol" bridges. By the action of NaCOOH on $Cr(NO_3)_3$ either I, II or III forms depending on the concn. and relative proportions. If NaCOOH is in excess III, $[Cr(HCOO)_6]Na_3.4H_2O$, is formed. III is readily sol. in H_2O, anodic, and forms dark violet rhombohedrons. The 4 mols. of H_2O are given off over $CaCl_2$ or H_2SO_4. The anhyd. salt is blue-green; this color change is caused by H_2O not in the complex. Since III is a neutral salt the acid from which it is formed is strong. A 0.1 *N* soln. of III changes in 20–30 days to II. More than 6 formato groups per 3 Cr atoms do not form complexes stable to H_2O. III is stabilized by NaOH but not by HCl. A certain acidity is necessary for the change III to II. Freshly prepd. basic solns. of I or III tan well. Cr absorption is much greater than with the acetate. Hide powder took up 10% Cr from a 0.1 N, 50% basic soln. of I. II has almost no tanning action. On aging or heating the tanning action is greatly decreased because "ol" bridges form; all secondary valences of the OH groups are linked to Cr atoms and so cannot react with hide. I. D. CLARKE

Synthetic tannins. LOUIS MEUNIER AND CHARLES GASTELLU. Ecole française de tannerie. *Chimie et industrie* Special No., 699–705(April, 1928).—See *C. A.* **22,** 1054. A. P.-C.

The oil tanning of skins. P. CHAMBARD AND L. MICHALLET. *Chimie et industrie* Special No., 706–15(April, 1928).—See *C. A.* **22,** 1055. A. PAPINEAU-COUTURE

Tanning products obtained as by-products in the manufacture of wood cellulose. RENÉ ESCOURROU. *Chimie et industrie* Special No., 623–33(April, 1928); cf. *C. A.* **22,** 4002.—A review. A. PAPINEAU-COUTURE

The measuring of the colors of tanning extracts. M. A. DE LA BRUÈRE. *Cuir tech.* **17,** 342–5(1928).—The personal equation in the measuring of the color of a tanning material may be eliminated by using a photoelec. cell with galvanometer together with color filters to provide monochromatic light from some strong source of illumination. J. G. NIEDERCORN

The production of tanning extracts in Russia. P. J. PAULOWITC. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* **5,** 169–70; *Chem. Zentr.* **1927,** II, 999.—In Russia, bark from pines is the most important material for obtaining tanning exts. The bark contains about 11% tannin and 7.7% non-tannins. The exts., which are very rich in sugar, have a d. of 18–22° Bé. and contain 19–25% tannin and 59–68% H_2O. Besides, willow bark with about 10% tannin is to be considered as a tannin-producing material. G. SCHWOCH

Tanning value of "Takaout" galls of Tamarix articulata. F. AND M. HEIM DE

Balsac and A. Deforge. *Cuir tech:* **17,** 347–9(1928).—A small tree, *Tamarix articulata* Wahl, native to Northern Africa, when bitten by a mite, *Eriophyes Tlaiae* Trab, forms upon its floriferous twigs galls contg. 41–56% tannin of the pyrogallol type. A tree can produce annually 20–25 kg. of galls. J. G. Niederkorn

Investigation of the galls of Pistacia Atlantica Desf. from Libya. Giuseppe A. Bravo. *Boll. ufficiale staz. sper. Ind. pellimat. concianti* **5,** 204–11; *Chem. Zentr.* **1927,** II, 1356–7.—A description of a domestic plant contg. a semi-solid oil, with a pleasant peanut-like flavor, m. 5–10°, d. 0.918. The leaves are attacked by gall wasps and produce galls in abundance. The wasps are: *Pemphigus cornicularius* Pass. (I), *P. Riccoboni* Stef. (II), and *P. utricularius* Pass. (III). Analysis of the galls showed:

	I	II	III a.	III b.
Tannins	24.04	29.21	37.76	40.32
Insol. non-tannins	20.33	25.74	15.28	12.72

Water	10.63	10.59	11.66	11.66
Ash	4.90	4.10	3.87	3.87

J. S. Reichert

The action of dilute tannin solutions on gelatin. A. Küntzel. *Collegium* **1928,** 460–3.—In dil. tannin solns., 0.05 to 2 millimols. per l., gelatin swells and the soln. becomes turbid. Swelling and turbidity are at a max. at the same tannin concn. As the concn. increases above this max., first the soln. becomes clear and the gelatin turbid and then the turbidity is absent. It is suggested that two substances, gelatin and gelatose, having different isoelec. points, are present. The gelatose is pptd. at tannin concns. at which gelatin still swells. After the gelatin begins to swell, gelatose cannot diffuse out and ppt. and so cause turbidity. The better grades of gelatin contain less gelatose and the swelling max. is at lower tannin concns. This may prove to be a *test for the purity of gelatin.* Other acid substances, such as picric, phosphotungstic or phosphomolybdic acids, show this same phenomenon with gelatin. I. D. Clarke

Casumo, a refined divi-divi. Johannes Paessler. *Ledertech. Rundschau* **20,** 105–6(1928).—Casumo is a refined divi-divi contg. about 60% tannin. I. D. C.

Gambier. Th. Körner. *Ledertech. Rundschau* **20,** 81–4, 98–101, 123–6, 141–3, 154–7, 166–72, 180–4(1928).—A review and discussion of the history of gambier, its cultivation, methods of extn. and its uses for dyeing, chewing with betel nuts, in pharmacy, etc. I. D. Clarke

Action of acids on vegetable-tanned leather. D. Woodroffe. *J. Intern. Soc. Leather Trades Chem.* **12,** 385–9(1928); cf. *C. A.* **21,** 3484.—Strips of vegetable-tanned goat skin were immersed in 10 times their wt. of 10% solns. of HOAc, lactic acid, oxalic acid, and H_2SO_4 for 2 months, dried, and tensile strengths were detd. Leather in 10% oxalic acid was practically destroyed. Leather in 10% H_2SO_4 was very much weakened as compared to leather in acetic and lactic acids. Leathers in 5% solns. of the same acids for 3 weeks decreased in tensile strength as follows: In acetic acid, 9%; lactic, 16%; H_2SO_4, 21%; oxalic, 59%. Loss in tensile strength is in the order of increasing H-ion concn. of the solns., except for oxalic acid. Short immersion of leather in warm 10% oxalic acid or H_2SO_4 had no measurable effect on the tensile strength, measured as soon as the leather was dried. Effect of acid on aging was tested by immersing pieces of 5 different vegetable leathers in 1 *N* solns. of oxalic acid, NH_4Cl, and H_2SO_4, and in 1% H_2SO_4, for 30 min., drying, and storing for 6 months. Control pieces were soaked in H_2O. Tensile strength of each piece was measured crosswise and lengthwise of the piece. Av. decrease in tensile strength for all leathers, as compared to controls, was: in *N* NH_4Cl, 14%; in 1% H_2SO_4, 25%; in *N* oxalic acid, 29%; in *N* H_2SO_4, 66%. Individual measurements showed very large deviations from these averages. Conclusion: "The ordinary, moderate use of oxalic or sulfuric acid is not detrimental."
H. B. Merrill

Hydrolysis of leather. G. Arbuzov. *Cuir tech.* **17,** 106–12, et seq. (1928); cf. *C. A.* **22,** 4271.—Material extd. from vegetable-tanned leathers by boiling in water showed in all cases a decrease in the ratio tannin/hide substance as the time of hydrolysis increased, until a const. value was reached at the end of 4 hrs. The equil. value for the ratio tannin/hide substance for oak- and oak-quebracho-tanned sole leather was 0.8, and for quebracho-tanned sole leather 0.65: for an upper leather tanned with willow bark ext. it was 0.48, and for willow-quebracho-tanned upper leather, 0.51. Conclusion: These equilibria indicate definite chem. compds. between hide substance and tannin, and these compds. vary with the nature of the tanning material and the method

of tannage. Vegetable-tanned hide powder showed increasing values for the ratio tannin/hide substance at equil. for exts. in the following order: wattle, sulfited quebracho, valonia, chestnut, myrobalans. Hide powder swelled with H_2SO_4 prior to tanning showed higher values. Hide powder tanned with $CrCl_3$ of various basicities and concns. came to equil. very quickly. From the data obtained by analysis of the material extd. the conclusion is drawn that the stoichiometrical laws apply to compds. of $CrCl_3$ with hide substance, but that several compds. are formed contg., resp., $^3/_2$, 1, and 3 equivs. of collagen per atom of Cr; leather is considered a mixt. of these 3.

J. G. NIEDERCORN

The investigation of aqueous leather extracts prepared by Proctor's method. ERICH BÜTTGENBACH. *Collegium* 1928, 444–9.—The H electrode should not be used with aq. leather exts. because the Pt electrode is poisoned. The quinhydrone and the indicator methods give reliable and agreeing values. The purity of the quinhydrone is of greatest importance in measurements on poorly buffered solns. In making measurements with the quinhydrone electrode, the metal electrode should be entirely surrounded by quinhydrone. Leather exts. are moderately buffered systems of weak acids having dissociation constants that are not far apart. The buffer curves show that phenolphthalein is the proper indicator for titrating dil. vegetable tannin solns. The rule that chlorides increase H-ion concn. holds for vegetable tannin solns. From the direction of the buffer curves the presence or absence of dangerous quantities of strong acids in the leather exts. can be detd. with certainty. The agent used to remove the fat from the leather (petroleum ether, cyclohexone, CCl_4, CS_2) has no influence on the p_H of the H_2O ext.

I. D. C.

Observations on the methods of stuffing [leather]. H. PRIEN. *Collegium* 1928, 295–8.—A brief, general discussion of oils, methods of preventing discoloration by the oil, etc.

I. D. C.

The use of the lecithin reaction for the qualitative detection of egg yolk in leather. NIKOLAUS JAMBOR. *Collegium* 1928, 459–60.—Egg yolk in leather can be detected by the following test for phosphate: Wash the leather with 1% NH_4OH soln. to remove finishing materials; cellulose pigment finishes must be removed with amyl acetate or other collodion solvent. Then ext. 10 g. of the leather with ether in a Soxhlet app., evap. the ether and add hot H_2O and 3 cc. of 10% NaOH to the residue. Boil for a few min., cool, acidify with AcOH, boil again for a few min. and filter. Acidify with HNO_3, add $(NH_4)_6Mo_7O_{24}$ soln. and warm gently. A yellow ppt. forms if lecithin (egg yolk) is present.

I. D. C.

The permeability of hide and leather. II. The permeability gases. MAX BERGMANN AND STEPHAN LUDEWIG. *Collegium* 1928, 343–51; cf. *C. A.* 22, 1249.—Duplicate measurements of permeability did not differ by more than 1%. An increase in moisture in leather decreases its permeability but humidity control is not absolutely necessary. The loss of air through the edges of the leather may be as much as 12% but this is prevented by placing a rubber ring around the leather in the clamp. Poiseuille's law was found to hold, *i. e.*, the volume of gas passing through the leather per minute, divided by the pressure is const. (K). There was no difference whether the gas was passed through from the flesh side to the grain or *vice versa*. Flesh splits were much more permeable than grain splits. The permeability of several leather pieces placed together can be calculated from that of each piece by the formula $(1/K) = (1/K_1) + (1/K_2) + (1/K_3)$........, where K_1, K_2, K_3 etc., are the consts. for each piece.

I. D. CLARKE

The permeability to water of sole leather. H. VAN DER WAERDEN. *Collegium* 1928, 453–8; cf. following abstract.—The app. described previously was used to det. the time required for H_2O to penetrate typical sole leathers. The time varied from 0.2 min. to about 7 hrs. W. concludes that a normal value for good leather cannot be assigned and that this test is of little value in detg. the quality of sole leather. Surface dressings or finishes can give the leather a greater resistance to H_2O temporarily but not permanently. The dressing should be removed from the grain and flesh sides before making measurements. The permeability is increased considerably by wetting.

I. D. CLARKE

The electrical determination of the permeability to water of sole leather. J. N. GEERSEN. *Collegium* 1928, 337–43.—The development is described of an elaborate app. for detg. the time required for H_2O to penetrate leather. The leather is held in a special clamp under a const. head of water. There is a p. d. of 40 v. across the leather. When H_2O penetrates the leather and closes the circuit a relay closes a second circuit which rings an alarm clock; then both circuits are automatically broken and the clock is stopped.

I. D. CLARKE

The action of sodium sulfide in the manufacture of sole leather. CASABURI. *Cuir tech.* **17**, 316–21, et seq.(1928); cf. *C. A.* **21**, 4089.—Theories of the action of sulfides in depilation are briefly reviewed. Solns. of 2 varieties of com. Na_2S of the same sp. gr. did not contain identical amts. of NaOH and NaSH, and in a series of tests differed slightly in their action upon portions of a Bahia hide. Tests were made upon sections of Bahia hide with solns. of Na_2S, Na_2S + NaCl, Na_2S + NH_4Cl, and Na_2S + $CaCl_2$. It is maintained that soaking may safely be omitted, and the skin brought directly into Na_2S solns. The quantity of hydroxyl alkali taken up by the skin is always the same in solns. of com. Na_2S, although the concn. may vary somewhat; the SH^- taken up varies with its concn. in the soln., about half of it being taken up. The addn. of NH_4Cl or $CaCl_2$ to the sulfide soln. is not strongly recommended, although it is preferable to the use of lime alone. Best results are obtained when NaCl is added to the Na_2S soln., giving a max. swelling and yield of leather when used in moderate concns. (Na_2S — $1^1/_2$° Bé., NaCl, 5.4 g. per l.). The yield of leather prepd. with Na_2S was greater than that from skin treated with lime only. J. G. NIEDERCORN

The manufacture of glove leather. M. E. AMSTERDAMSKY. *Cuir tech.* **17**, 278–81(1928).—A description. J. G. NIEDERCORN

An aid in dyeing: the mordant RS. V. CASABURI. *Cuir tech.* **17**, 297–304(1928).—See *C. A.* **22**, 3783. J. G. NIEDERCORN

Correctly dyed upholstery leather. FRANZ FAMMLER. *Ledertech. Rundschau* **20**, 110–1(1928).—To prevent dye from rubbing off of finished leather the leather should be warmed before dyeing and the dye soln. should be dil. I. D. C.

The dyeing of velvet or suede leathers. J. W. LAMB. *Dyer, Calico Printer* **60**, 94–5, 141(1928).—A method based on the use of ammonium acetate combined with the color is recommended for assisting penetration of the dyestuff. Some typical recipes for obtaining different colors and black are given. RUBY K. WORNER

Industrial waste work of the sanitary district of Chicago [tannery waste] (MOHLMAN) **14**. Analysis of fats (GILLET, *et al.*) **27**. The fluorescence of wood pulps and vegetable tanning extracts (GERNGROSS, *et al.*) **23**. Textile fibers from skins of sharks, etc. (tanning) (Brit. pat 284,297) **25**. Wetting out and dyeing or other treatments of leather (U. S. pat. 1,686,836) **25**. Leather substitute (Russ. pat 4159) **30**. Extracts from glands of sharks, etc. [for treating skins before tanning] (Brit. pat. 284,668) **17**.

Unhairing and preparing skins. CHARLES J. M. M. LE PETIT. Fr. 32,554, June 12, 1925. Addn. to 609,316. Enzymes produced by the cultivation in a suitable medium of *Aspergillus oryzae* are used for unhairing skins. Cf. *C. A.* **21**, 1371.

Depilatory. R. BOTSON. Brit. 285,152, Nov. 11, 1926. See Can. 275,518 (*C. A.* **22**, 1249).

Depilating and softening hides. SOC. PROGIL. Brit. 284,719, Feb. 4, 1927. Enzymic liquids which may be prepd. by the use of bacteria such as *B. subtilis*, *B. mesentericus* or *B. liquefaciens* (developed in peptonized gelatin or meat ext. and centrifuged) are used in depilating and softening skins prior to tanning. In treating goat skins, NH_4Cl also is used, and with sheep skins Na_2CO_3, in treatments effected at a temp. of about 37°.

Tanning leather. A. A. FEDOTOV. Russ. 4556, Sept. 15, 1924. $(NH_4)_2SO_4$ and a mixt. of alkali and alk. earth salts with sulfonated aliphatic or aromatic compds. are used for softening sole leather which also act as reducing agents when the leather is later treated with a chromate soln. after it was treated with N or without this treatment.

Tanning leather. JOHANN G. KÄSTNER. Fr. 635,227, May 30, 1927. A decoction of stones from different kinds of carobs is added to the tanning substances.

Tanning and auxiliary treatment of fish skins. A. EHRENREICH. Brit. 284,197, Jan. 24, 1927. Before or after tanning, dermal armor is removed from the skin of sharks or the like by use of H_3PO_4 or HF, with or without addn. to the bath of salts such as NaCl, alkali metal or other salts of H_3PO_4 or HF or salts such as those Cu, Ni, Pb or Al which act as catalytic accelerators as does also an elec. current of low voltage. Jets of compressed air may be used for circulating the liquid. Cf. *C. A.* **22**, 2855, 3801.

Emulsifying agent from fish roe. A. EHRENREICH. Brit. 284,707, Feb. 4, 1927. Roe of sharks or similar fish roe is reduced to a paste and mixed with a preservative or dried *in vacuo* at 40–50° to obtain a product suitable for use as an emulsifying agent in the *manuf. of greases for use in the leather industry*, etc.

Leather substitute. N. I. TIKHOMIROV. Russ. 3586, Sept. 15, 1924. Xanthate of the epidermis is formed from vegetable fibers on the surface of the tissue by treat-

ment with a soln. of KOH under pressure and later with CS_2 vapor; the xanthate is then decomposed as usual.

Glue. STOCKHOLMS BENMJOLSFABRIKS AKTIEBOLAG. Brit. 284,704, Feb. 4, 1927. A glue soln. is allowed to fall in drops which strike separately on a moving surface such as a belt or revolving cylinder (which may be treated with powd. materials such as talc, chalk, H_3BO_3, pulverized glue or starch) and are cooled to form stiffened drops or granules.

Glue. A. EHRENREICH. Brit. 284,593, Jan. 31, 1927. Skins, pectoral and other fins, cuttings or waste from fish such as plagiostomi are washed to remove solid impurities, "dissolved" at a temp. of not over 80° to produce a viscous fluid, which is skimmed to remove further impurities, evapd. *in vacuo* until it contains about 70% of water, agitated to produce a frothy mass and further dried *in vacuo* to produce flake glue. Powder glue may also be made by carrying the agitation further before drying or by crushing the flake product. Compressed air may be used for the agitation and an app. is described. Cf. *C. A.* 22, 883.

30—RUBBER AND ALLIED SUBSTANCES

Priestley, the English godfather of rubber. A. DUBOSC. *Rev. gén. caoutchouc* 5, No. 44, 7–8(1928).—Historical sketch. C. C. DAVIS

"Mineral rubber." An historical point. A. D. LUTTRINGER. *Caoutchouc & gutta-percha* 25, 14157(1928).—Old references to "mineral rubber" are cited to show that the term has been in use for many years. C. C. DAVIS

Mechanical tests of rubber and probabilities. R. FRIC. *Chimie et industrie* Special No., 541–6(April, 1928).—A mathematical discussion based on the results obtained in tensile tests of 732 test samples as nearly the same as they could be made. A. PAPINEAU-COUTURE

Methods for controlling changes in rubbers. J. VILLEY AND P. VERNOTTE. *Chimie et industrie* Special No., 534–6(April, 1928); cf. *C. A.* 19, 1208.—A discussion of the conditions which should be fulfilled by methods for following and estg. quantitatively the changes in rubber on aging. Two of the important requirements insisted upon are that the test sample should not be destroyed so that the change in the rubber may be followed right through on the same sample, and that the results should be capable of numerical expression. Two methods are suggested as suitable, a torsion test, and a dielec. test (*C. A.* 18, 2617). A. PAPINEAU-COUTURE

The development of rubber reclaiming since the War and its importance in the economics of rubber. PAUL ALEXANDER. *Gummi-Ztg.* 42, 2796–8(1928).—Historical. C. C. DAVIS

Present researches in the rubber industry. ANDRÉ BLOC. *Science & industrie* 12, No. 170, 37–41; No. 174, 47–9.—An illustrated review and description, dealing with new methods and improvements in the *prepn. of raw rubber*, the *electrolysis of rubber*, the *use of concd. latex, synthetic rubbers, org. accelerators, antioxidants* and the *manuf. of reclaimed rubber*. C. C. DAVIS

Investigations on the structure of rubber. PAUL BARY AND ERNST A. HAUSER. *Rubber Age* (N. Y.) 23, 685–8(1928).—English version of the article in *C. A.* 22, 4005. C. C. DAVIS

The effect of heat on raw rubber in the presence and absence of air. J. D. FRY AND B. D. PORRITT. *Trans. Inst. Rubber Industry* 3, 203–16(1927).—Mech. working, heat and atm. O are all responsible for the phys. changes accompanying milling. Of these mech. work and heat are already considered to be responsible for the plasticizing effect, and the influence of O has not been realized. The present paper shows the important *part played by O* and the different effects produced in its presence and absence. The effect on the soln. viscosity was first detd. by heating rubber in air at different temps. from 100° to 150°, under which conditions it was found that the higher the temp. the lower was the subsequent soln. viscosity. Rubber milled to different extents was then heated in air at different temps. from 106° to 180° for different periods (30 min. to 4 hrs.), after which the soln. viscosities of the products were detd. By comparing the *effect on the soln. viscosity of the time of milling and the time of heating*, it was found that around 100° heating had relatively little effect, but above this temp. the effect of heat became greater and at 150° the curve of viscosity against time of heating closely approximated the curve of viscosity against time of milling. The chief effect produced by milling can therefore be duplicated by heating rubber at 150° for a few hrs. The

curves were of an exponential character and suggested a *chem. reaction*, for which reason the expts. were repeated under identical conditions with different proportions of air and *in vacuo*, H, N and steam. *In vacuo*, H, N or steam there was little change in viscosity even after heating 4 hrs. at 150°, whereas in air the viscosity diminished with increase in the proportion of air. Thus with 1 g. of rubber in 9 cc. of C_6H_6, the viscosity was 469 with no O, decreased to 393 with 0.000046 g. of O, to 317 with 0.000103 g., to 160 with 0.000491 g., to 99 with 0.000989 g. and to 57.6 with an unlimited air supply. The results show that both O and heat are necessary to obtain the ordinary effect produced by milling, and that if the only change desired is reduction of the soln. viscosity, the results accomplished by milling may be reproduced by heating in the presence of O. The mechanism of this action of O and heat remains undetd. A general discussion follows the paper. C. C. Davis

The hardness testing of vulcanized rubber. T. R. Dawson. *Trans. Inst. Rubber Industry* **3**, 217–33(1927).—A crit. survey of various methods of measuring the hardness of rubber, with a description of the principles and technic of the *durometer, plastometer* and *scleroscope* types of app., with references to the literature on the subject. In tests of different rubber mixts. at different temps. (60–80°F.) with a Shore scleroscope, the rebound increased in direct proportion to the increase in temp., and decreased with increase in the time of cures. The magnitude of this increase with temp. varied greatly with the compn. of the mixt. The variation with time of cure was of minor importance; the scleroscope measures primarily the resilience and is useless for detg. the state of cure. In general with increasing proportion of filler or pigment, the resilience decreased progressively, in direct contrast to metals where the harder the metal the greater the scleroscope rebound. *Application* for the first time *of the Herbert pendulum to rubber* showed that the time of swing decreased with increase in the proportion of fillers or pigments, *i. e.*, with increase in hardness, again in contrast to the behavior of metals. A graphical *comparison of plastometer and scleroscope tests* showed an essentially linear relation between the 2 series of values, while the proportional changes depended upon the filler or pigment. In conjunction with previous work, the expts. indicate that the fundamental factors governing dynamic indentation tests also play the chief role in static identation tests. C. C. Davis

Investigation of the structure of stretched rubber. Lothar Hock and Walther Barth. *Z. physik. Chem.* **134**, 271–8(1928).—X-ray photographs of stretched synthetic Me rubber at −60° show interference bands with sharp edges and weak center indicative of a tendency toward line formation in nearly the same positions as the lines of stretched natural rubber. G. L. Clark

Present knowledge of the constitution of the rubber molecule. S. C. J. Olivier. *Chimie et industrie* Special No., 537–40(April, 1928).—A brief critical review of the various theories proposed as to the chem. constitution of the rubber mol. A. P.-C.

The orderly micellar structure of rubber. H. Mark and G. v. Susich. I. G. Farbenindustrie A. G. *Kolloid-Z.* **46**, 11–21(1928).—When pieces or films of natural rubber are stretched greatly an orientation within the member takes place not only in the direction of stretch but in the directions at right angles to it. X-ray analysis of such a crystd. prepn. assigns the stretched rubber to the rhombic crystal system. The identity period of the elementary units is a = 12.3, b = 8.3, c = 8.1 A. U. The no. of isoprene residues in the elementary unit is 8. The crystal class is probably V or V_h. Possible crystal structures are discussed and a space distribution of the C atoms is proposed which brings into agreement the orientation of the primary valence chains in the direction of stretch, the somewhat altered atom spacing for the C=C and C=C linkages, and the observed intensities of the most important interference bands. Several chem. reactions are described, by means of which it was sought to convert stretched rubber into derivs. retaining the structure, much as is the case in a number of topochem. reactions of cellulose. The rubber derivs. gave the x-ray pattern for amorphous material. F. L. Browne

The two coagulations of latices. René Audubert and G. Lejeune. *Rev. gén. colloïdes* **5**, 713–22(1927).—Only fresh *Hevea* latex was used by de Vries when he proved that under certain conditions it can be coagulated twice in succession with an intermediate dispersed state. This suggested similar expts. with *Hevea* and *Landolphia* latices preserved with NH_3, and with p_H values much greater than those of de V. Excess NH_3 was first removed by evapn. *in vacuo*, giving a product with p_H of 9–10. In all cases the concns. of the acid solns. added were so adjusted that regardless of the quantity of acid, the vol. added made the new vol. twice the original vol. Redispersion and recoagulation are most distinct with *Landolphia* and AcOH. When the latex has a high rubber content, *viz.*, above 25%, coagulation is normal and increas-

ing proportions of acid merely accelerate the single and final coagulation. When the latex contains 15–25% rubber, addn. of acid (1) first causes complete coagulation (clear serum), (2) then redispersion into the form of agglutinated globules, which pass through a max. condition, and (3) finally complete coagulation a second time. In latex contg. less than 15% rubber, the redispersion is still more pronounced and complete so that the mixt. becomes completely liquid again; nevertheless a second coagulation takes place with still more acid. Throughout the redispersion, the elec. charge on the granules remains negative, so that the redispersion cannot be explained by an electro-capillary inversion of the globules, the concn. of acid at the time corresponding to the isoelec. point of rubber. When casein or gelatin is first added to the latex, coagulation is still abnormal, though different insofar as the same charges occur at lower p_H values. With casein or gelatin, the first agglutinated aggregates have a negative charge, whereas the flocculates of the second coagulation have a positive charge. The p_H corresponding to this inversion of charge is not near the isoelec. point of the protein (4.7) but is more strongly acid, *viz.*, 2–3. This suggests that the casein or gelatin envelops the rubber globule so that the inversion of the charge of the micelles comprising this protective film governs the inversion of the charge of the globule + film. The difference between the p_H of inversion and that of the isoelec. point of the casein or gelatin indicates that the charge of the rubber plays a part, but that the natural protein does not. The natural protein is sep. from the rubber globule (peptized) both in the original latex and during the period of redispersion, and can be removed by dialysis. Assuming that the isoelec. point of the natural protein is in the alk. region, a negatively charged latex globule adsorbs the protein micelles, the resultant, rubber-protein remaining negative. A small increase in H ions diminishes this charge, with adsorption of H ions. With further addn. of H ions the negative charge is so much reduced that agglutination and coagulation follow. With the addn. of still more H ions, the negative charge is so greatly diminished that the protein micelles are liberated and peptized and the coagulated rubber reverts to a state of agglutination. Finally with more H ions, the protein is coagulated and its network structure entraps the agglutinated globules, causing the second coagulation. C. C. DAVIS

Dispersoidological investigations of latex. P. P. VON WEIMARN. *Bull. Chem. Soc. Japan* **3**, 157–68(1928).—Latex preserved with NH_3, concd. latex (80% rubber) and vulcanized latex were used in the expts. In NH_3-preserved latex, particles of every shape described by previous investigators were found, the no. of ultramicroscopic particles being considerably greater than the no. of microscopic ones. A comparison of photomicrographs of *Hevea* latex and the latex of *Ficus elastica* and of gelatinous spherulites of cellulose (cf. *C. A.* **22**, 873, 4028) indicated that in some latexes emulsion-suspensions of gelatinous isospherulites are present, probably in the aggregate-fluid-cryst. state. The film surrounding the viscous internal fluid of latex particles is, contrary to Freundlich and Hauser, probably composed of a mixt. of rubber and protein particles. In conjunction with the works of previous investigators, it is concluded that latex is a polydisperse system of isoaggregate particles (isospherulites), the general consistency of which is fluid and gelatinous. The individual solid particles composing the isoaggregate particles are for the greater part invisible under the ultramicroscope. The components of the serum (the dispersion medium in which the isoaggregate particles are suspended), *viz.*, proteins, water, resins, etc., are present not only in the surface film but also inside the isoaggregates. The non-rubber components play corresponding roles in the changes in consistency and structure which the isoaggregates undergo during drying and other coagulation processes. The high elasticity of rubber depends upon the presence in the viscous liquid or gelatinous medium of solid structural elements which possess the ability to become spirally curled after release from tension. The *gelatinization of latex by extremely concd. aq. solns. of dispergators of proteins, e. g.*, LiI, LiSCN, $Ca(SCN)_2$, NaI, $Ca(NO_3)_2$, $CaCl_2$, polyphenols, pyrogallol, resorcinol, thiourea, guanidine thiocyanate, AcOH and KOH solns. and by *aggregators of proteins, e. g.*, Na citrate, KNa tartrate and K_2SO_4, was also studied. At suitable temps. and concns., dispergators cause almost immediate and complete gelatinization, with formation of a coherent jelly. This can for instance be brought about by agitating at room temp. an equal vol. of satd. aq. LiI or LiSCN with latex. The structure of these jellies is such that they have greater strength longitudinally than transversely, and the higher the temp. of formation the stronger they are. These coherent jellies show syneresis. Aggregators of proteins do not coagulate rubber in latex, at room temp., even after long standing, but by pouring latex into boiling concd. solns. and continuing the boiling, flaky coagula are obtained. By coagulation of latex through addn. of concd. solns. of silk, casein, chitin or keratin in aq. solns. of dispergators,

coagula of mixed compn. are obtained, *viz.*, *rubber-silk*, *rubber-casein*, *rubber-cellulose*, *rubber-chitin* and *rubber-keratin*. The properties of these mixts. are under investigation. When vulcanized latex is gelatinized by the addn. of aq. solns. of dispergators, the jellies are weaker than those formed from raw latex, but by compression the tensile strength is increased. C. C. DAVIS

Purification and fractionation of rubber. VII. RUDOLF PUMMERER, ALBRECHT ANDRIESSEN AND WOLFGANG GÜNDEL. Univ. Erlangen. *Ber.* **60B**, 1583–91(1928); cf. *C. A.* **22**, 886.—*I. Alkali purification of latex concentrate.*—As shown in the earlier papers fresh latex and that preserved with NH_3 behave differently towards alkali. Expts. with the latex concentrate "Revertex" have further shown that the latex preserved with NH_3 has been altered in still another way. The statement of P. and Pahl that their "total rubber," obtained from NH_3-preserved latex with alkali, is protein- and N-free, needs correction. Even after most thorough and prolonged treatment with alkali at 50°, it still contains 0.15–0.4% N. On combustion with a reduced Cu spiral the C and H values add up to about 0.4% less than 100%, and as a substance with 0.4% of protein N should show a deficit of about 1% (because of the O present), the N remaining in this NH_3-preserved latex after purification with alkali must be amine N, evidently produced by the action of the NH_3 on the latex during the more or less protracted period of preservation. A gel rubber with 0.4% N refluxed 1 day in C_6H_6 with dil. NaOH yielded no amino acids (ninhydrin reaction) to the aq. alkali, nor did the rubber itself give the ninhydrin test when boiled with the reagent. On the other hand, ordinary "Revertex" yields a "total rubber" with only 0.04–0.1% N which is increased to 0.17% in the "gel rubber" remaining after the "total rubber" is extd. with Et_2O. A prepn. similar in properties to the repptd. gel rubber and still contg. 0.15% N can also be obtained by allowing the gel skeleton from crepe to swell in C_6H_6 and pptg. the clear C_6H_6 soln. after some weeks. "Sol rubbers" from crepe also often have a similar N content. *II. Fractional ether extn. of different latex and raw rubber prepns.*—Various rubber prepns. were extd. continuously in an app. which is described. (1) The extn. curve (with Me_2CO) for a purified "total rubber," prepd. from preserved latex with NaOH according to P. and Pahl, showed a distinct inflection after about 40 hrs. when 65–70% of the total rubber had dissolved, and after that there is very little further soln. (finally only 0.2–0.3% in 24 hrs.); the residue and these last slowly-dissolving traces are apparently gel rubber, and as the soly. of the residue from the 10th to the 30th day remains practically const., the gel rubber, insofar as it dissolves, must be quite homogeneous. (2) The extn. curve for NH_3-preserved latex, such as used for the alkali purification for (1) but merely freed of H_2O-sol. substances by dialysis, then coagulated and extd. with Me_2CO, rises much more slowly than that for (1) and in 850 hrs. the quantity extd. is still far less than in (1) after 50 hrs. There is an inflection, but not so marked, in this curve also. (3) The curve for Para crepe is remarkably similar to the preceding curves. After 52% has been extd., very little more goes in soln. Such an Me_2CO-extd. crepe, freed of Me_2CO in a high vacuum, is not immediately suitable for fractional extn. with Et_2O as it swells up and breaks up into minute flocks which are carried over by the solvent, but after it has stood 3 months under CO_2 Et_2O exts. from it the sol rubber more rapidly and in larger quantity than originally (55% in 45 hrs., the stationary stage being reached in 150 hrs.); after 700 hrs. only 16.8% residue (gel skeleton) remains. The same Me_2CO-extd. crepe, allowed to stand 1.5 yrs., gave a greater quantity (28.1%) of gel skeleton. The sol rubber thus obtained contained 88.18% C and 11.94% H, the gel skeleton 81.35% C, 11.06% H, 2.06% and N, 1.02% ash. The latter was allowed to stand 6 weeks under C_6H_6, and the clear C_6H_6 liquid then evapd. *in vacuo*, yielding a gel rubber with 88.23% C, 11.88% H and 0.15% N. To det. whether or not the increase in sol rubber after extn. with Me_2CO was due to the heating rather than the action of the Me_2CO, 1 sample of *raw* crepe was heated 6 days at 60° under CO_2, and another allowed to stand 6 days in Me_2CO, and the 2 samples, together with a 3rd of untreated crepe, were allowed to stand 6 days under Et_2O with occasional shaking. The 1st yielded 82.3, the 2nd 56.7, the 3rd only 40% sol rubber. The increased sol rubber yield is therefore chiefly a thermal effect. After standing a yr. under CO_2 the gel skeleton yielded to Et_2O 4.6% more rubber than calcd. from its extn. curve at the time of its prepn.; after heating 30 days at 60–5° it contained 27.5% sol rubber. (4) With the continuous extn. method the sol rubber in smoked sheet dissolves rapidly in Et_2O; the curve shows a quite marked inflection at 70% extn. after 60–70 hrs.; final value after 700 hrs., 86%; the gel skeleton contains 77.89% C, 10.90% H, 3.26% N, 1.91% ash. *III. Relations between sol and gel rubber.*—These depend on the previous history of the prepn. and can well be explained on the basis of an equil. attainable from both sides, but, as already

pointed out (*C. A.* **22,** 4005) not all sol fractions are involved uniformly in the assumed "equil." **VIII. Preparation and molecular size of isorubber nitrone.** RUDOLF PUMMERER AND WOLFGANG GÜNDEL. *Ibid* 1591–6.—P. and G. have been studying Bruni and Geiger's isorubber nitrone (I) (*C. A.* **21,** 4092) to see whether it might be used to distinguish between sol and gel rubber and to det. the mol. wt. of the rubber mol. Only PhNO was used. As a whole B. and G.'s observations were confirmed, but with PhNO it is very difficult to prevent a slight absorption of O, especially when, according to B. and G.'s general method, the components are warmed 15 min. in C_6H_6 on the H_2O bath. I, both in soln. and in solid form, is far more sensitive than rubber to O. It is best to work in the cold and in as concd. a soln. as possible in C_6H_6 under CO_2 or N_2. The originally very viscous soln. becomes mobile in 20–30 min., while the whole reaction requires 1–2 days, depending on the temp., for its completion. In C_6H_6 and $PhNO_2$ the I produces depressions of the f. p. corresponding to a mol. wt. of 1200–1400 (calcd. for a substance formed from a rubber mol. with 8 isoprene groups condensed with 8 mols. PhNO with loss of 16 H atoms, 1384). As in the menthol detns. on rubber, the measurement must be taken only when constancy is reached (1–2 hrs.); after this, the value does not change in 14 hrs. The conclusions previously reached (from the menthol detns.) as to the size of the rubber mol. are thus confirmed. C. A. R.

Plasticity determinations in crude rubber. VI. Changes in plasticity on keeping the rubber. O. DE VRIES. Proefstation voor Rubber, Nederlandsch-Indie. *Arch. Rubbercultuur* **12,** 411–9(1928) (Summarized in English 420–2); cf. *C. A.* **22,** 3316.—Various samples of smoked sheet and of pale crepe which had been kept for long periods were tested to det. changes in their plasticity, viscosity and vulcanizing properties. The results showed considerable variations, some rubbers changing much faster than others. Rubber 12 yrs. old was still in fairly good condition. C. C. DAVIS

A new plasticizing agent for rubber. PATSCHKE. *Caoutchouc & gutta-percha* **25,** 14156–7(1928).—*Caoutchol* is a brown-black oil, with an odor resembling pine tar, and practically non-volatile below 200°. It is a true softener according to the terminology of Burbridge (cf. *C. A* **21,** 1030). It has antioxidant properties, is a mild accelerator, and is useful in reclaiming. C. C. DAVIS

Stress-strain curves for plastic sulfur and raw rubber at various temperatures. JOHN D. STRONG. *J. Phys. Chem.* **32,** 1225–30(1928).—Detns. of the stress-strain curves of raw rubber and of plastic S at various temps., in which the data were recorded automatically and were practically independent of plastic flow, showed that there is a marked similarity between the curves of these 2 substances, the same characteristic influection point being evident in each case. The *prepn. of plastic S* was carried out by pouring the S into aq. NaCl below 0°, under which conditions it was of a clear yellow color and retained its elastic properties for many hrs. With a means of stabilizing this elasticity, plastic S should be a satisfactory and cheap *substitute for rubber.* C. C. DAVIS

Sulfur and selenium. WEBSTER NORRIS. *India Rubber World* **78,** No. 4, 60–2 (1928).—A description, from the historical point of view, showing the results obtainable with the use of Se in conjunction with S. C. C. DAVIS

Elastic behavior of india rubber. G. B. DEODHAR AND D. S. KOTHARI. *Indian J. Physics* **2,** 305–18(1928); cf. *C. A.* **17,** 1917.—A dynamical method is described for detg. the variation of the modulus of rigidity of rubber with stress. Tests of 3 samples showed that the rigidity increases linearly with stress up to the breaking point A qual. study of the effects of heat shows that a stretched band, when heated to about 100°, contracts, but if the heating is stopped the band extends until its length exceeds that before heating, and this extension is permanent. It is possible that, just after heating, the rigidity falls considerably, but after some time it regains almost its initial value at that load. The logarithmic decrement, unlike that of a metal, decreases with the load. The behavior of metals is similar, the difference being one of magnitude only. In variation of "torsional stiffness" with load, the behavior of rubber seems to resemble that of annealed wire. B. C. A.

New developments with dispersed rubber. H. A. WINKELMANN. Philadelphia Rubber Works Co. *India Rubber World* **78,** 53–5(1928).—A description of the more recent developments (cf. Tuttle, *C. A.* **17,** 2204; **18,** 1065; **19,** 1207, 1792; Pratt, *C. A.* **18,** 2086; **19,** 420; **20,** 678; **21,** 291, 1568, 3767). Aq. dispersions are finding an increasing no. of uses outside of the rubber industry, notable among which are in the textile and paper industries. Thus in the *textile industry,* aq. dispersions can be used in the manuf. of automobile topping, rugs, mats, upholstery, raincoats, bags and webbing. In the *paper industry,* pulp may be impregnated with dispersed rubber, besides which it is used in the manuf. of bags and wall board. Other newly developed

uses, some in an exptl. stage, are described. The technic of the prepn. of aq. dispersions has been improved, including the use of a variety of *dispersing agents* to suit best the particular problem, such as fatty acids, soaps, glues, saponins, sea moss, albumins and clays. The types of rubber, or rubber mixts. which it is possible to disperse are practically unlimited, and uniform consistency, concn. and quality are readily secured.
C. C. Davis

Dispersion of pigments in rubber. I. Microscopical studies of agglomeration and flocculation. Ernest A. Grenquist. Fisk Rubber Co. *Ind. Eng. Chem.* **20**, 1073–8(1928).—The tendency during milling of particles to pack and form secondary units is defined as "*agglomeration*," and dense formations of completely dispersed particles originating during vulcanization as "*flocculation*." "*Aggregation*" refers to cases where agglomeration and flocculation cannot be distinguished. A review of the literature (63 references to which are given) deals with the various factors which govern the dispersion of pigments in rubber, especially agglomeration and flocculation. Expts. are then described in which various pigments, including S, C black, ZnO, stearic acid, di-*o*-tolylguanidine in various combinations, were mixed in rubber and their state of dispersion, agglomeration and flocculation were detd. microscopically. In many cases the behavior was similar to dispersed particles in other systems. Agglomeration occurs around larger foreign nuclei. During vulcanization or even during heating of a rubber-C black mixt., flocculation of previously dispersed particles occurs, the causes and effects of which seem to vary with the components and the conditions.
C. C. Davis

Organic rubber colors. W. J. S. Naunton. *Trans. Inst. Rubber Industry* **4**, 68–84(1928).—A crit. review and discussion of present developments in the use of org. colors in rubber, with certain new data. Tests of the aging effects of some typical org. colors compared with red Fe oxide and ultramarine showed that, in general, org. colors do not have a deleterious effect on natural aging, but may hasten deterioration when the rubber mixts. are heated in air at 70°, unless protected by an antioxidant. The problems encountered in the use of org. colors in latex to be vulcanized or electrolyzed and in dry rubber mixts. are then discussed. Colors can conveniently be divided into those (1) sol. in rubber; (2) slightly sol. in rubber, and (3) insol. in rubber, the latter class including org. pigments and lakes. Sol. colors must not be used in proportions above the soly. limit; otherwise they crystallize out (bloom). At ordinary temp. this limit is about 0.3% in pale crepe. Some substances (*e. g.*, Fe oxide) promote this crystn. and blooming; others inhibit it. Incorporation of colors in rubber may be facilitated and made more nearly uniform by converting the colors to their stearates by preliminary fusion with stearic acid. Colors slightly sol. in rubber have certain advantages which make them the most satisfactory class. In making transparent rubber, Zn and Cd stearates are the best activators, Cd stearate being preferable in most cases. Various troubles are also encountered in the manuf. of various colored ebonites, which may be minimized by the proper combination of S, accelerator, choice of color and conditions of curing. A general discussion follows the paper. Also in *Rubber Age (London)* **9**, 254–61(1928). C. C. Davis

Carbon blacks and their use in rubber. III. Aging effects. L. B. Cox and C. R. Park. Delano Land Co., Los Angeles. *Ind. Eng. Chem.* **20**, 1088–91(1928).—In continuation of the earlier expts. (cf. Goodwin and Park, *C. A.* **22**, 3802) the influence of the various blacks on the aging of rubber mixts. contg. the blacks was studied. Changes in the tensile strength and resistance to abrasion and increases in wt. were used as criteria of the aging. The aging varied with the different blacks, the best aging being obtained with Thermatomic, followed by Goodwin, Charlton, Micronex and Super Spectra in the order named. With respect to the influence of accelerators on the aging, the beneficial influence increased in the order: diphenylguanidine, hexamethylenetetramine, ethylideneaniline, mercaptobenzothiazole. Stearic acid showed no influence on the aging properties of the vulcanizates. C. C. Davis

Critical discussion of results of tests of carbon black mixings with reference to hysteresis losses and the relation of these tests to the resistance to deterioration. Lothar Hock. *Kautschuk* **1928**, 89–90.—Tests, based on an earlier publication by H. (cf. *Kautschuk* Sept. 1925), are described, in which the influence of "Durex" C blacks in an accelerated rubber mixt. was detd. C. C. Davis

Critical discussion of tests of carbon black mixings. Werner Esch. *Kautschuk* **1928**, 115–6.—Comments on a paper by Hock (cf. preceding abstr.) C. C. Davis

Recording roll heat of calenders. C. E. Maynard. Fisk Rubber Co. *India Rubber World* **78**, 62(1928).—A new *automatic app.* is described and illustrated.
C. C. Davis

Reënforcement of rubber by fillers. JOHN T. BLAKE. Simplex Wire & Cable Co., Cambridge, Mass. *Ind. Eng. Chem.* **20**, 1084-8(1928).—A new *theory of the reënforcement of rubber by pigments* is advanced, in connection with which a reënforcing filler is considered to be one which forms a bond with the rubber which is stronger than the matrix itself. The ΔA function of Wiegand (cf. *C. A.* **19**, 3386) is a practical means of expressing the reënforcing effect of a filler, but the range of vol. over which the bonding of the filler is greater than the strength of the rubber matrix gives a better understanding of the condition of the filler in the rubber. A "*mol. tensile*" *curve* serves to illustrate and substantiate this point of view. The *mechanism of the dispersion of fillers or pigments* is then studied theoretically, the work of Langmuir and Harkins being adapted to show that the fatty acids and esters are responsible for the wetting and dispersion of the particles. Calcns. of the quantity of these dispersing agents and of the heats of wetting conform to the exptl. values. In this way the *role of fatty acids and other polar compds.* is put on a sound theoretical basis. Rubber mixts. may be improved by delaying the break in the mol. tensile curve by increasing the range over which dispersion is complete. C. C. DAVIS

Balata gum. A. D. LUTTRINGER. *Caoutchouc & gutta-percha* **25**, 14,111-5, 14,154-6(1928); cf. *C. A.* **22**, 4005.—A general treatise on the characteristics and uses. C. C. DAVIS

The aging of rubber. Its preservation. F. JACOBS. *Caoutchouc & gutta-percha* **25**, 14,110-1(1928); cf. *C. A.* **22**, 1057, 4004.—Some of the most recent aging tests, such as the Marzetti O test (cf. *C. A.* **17**, 2975), the aging wheel of the Office des Inventions (cf. *C. A.* **21**, 1899) and the Hanau analytical lamp (cf. Krahl, *C. A.* **21**, 2816), are described. C. C. DAVIS

Changes in composition of rubber on aging. M. SAGAJLO. *Przemysl Chem.* **12**, 184-90(1928).—Analyses of several rubber mixts. showed that on aging not only the acetone-sol. content but also the $CHCl_3$-sol. content and substances saponifiable in alc. KOH increase in the rubber. A. C. ZACHLIN

Laboratory devices for studying the aging and vulcanization of rubber. R. FRIC. *Chimie et industrie* Special No., 547-8(April, 1928).—A detailed description of a pressure oven for carrying out artificial aging tests in air or O_2 under pressure, as suggested by Bierer and Davis. Heating is obtained by induced currents. A. P.-C.

American vulcanization accelerators. RUDOLF DITMAR. *Chem.-Ztg.* **52**, 730 (1928).—The characteristics of the Am. accelerators termed in the trade *A*-11, *A*-16, *A*-19, *A*-20, *A*-50 and *Z*-88 are described briefly, including their fluorescent colors in ultra-violet light. C. C. DAVIS

A scheme for accelerator classification. R. P. DINSMORE AND W. W. VOGT. Goodyear Tire & Rubber Co. *Rubber Age* (N. Y.) **23**, 554-7(1928).—See *C. A.* **22**, 4273. C. C. DAVIS

The microscopy of the vulcanization of rubber. ERNST A. HAUSER AND M. HÜNEMÖRDER. *Caoutchouc & gutta-percha* **25**, 14146-9(1928). (Accompanying illustrations on sep. sheet.)—An *app.* is described, with which it is possible to observe continuously the changes which rubber mixts. undergo when heated. In 1 modification of the app., tiny samples are heated directly in steam, in another modification they are heated under compression indirectly by steam, in each case steam under known pressure being passed through or around the chamber contg. the sample, the latter being under observation through a microscope. By this means it was possible to observe the *behavior of S during vulcanization.* At a pressure of 3 atms., the S fused, the total mass became semi-fluid and the droplets of S dissolved in the rubber without any intermediate phase (cf. Dannenberg, *C. A.* **21**, 835, 3764). The mass then remained optically empty, but soon after the heating was stopped, droplets of S appeared in continuously increasing no. These droplets then migrated to form chains. The longer the heating the less was this tendency for S to sep. and form chains. With accelerators present, fusion of S began sooner, general softening of the mass was less, and instead of droplets forming chains, the S sepd. directly on the surface in rhombic form. The same general phenomena took place with ZnO, though softening and subsequent sepn. of S were less pronounced. Colloidal ZnO behaved somewhat similarly to S, dissolving during vulcanization and sepg. again later. The app. is applicable to the study of the *behavior of compounding ingredients in general.* A review of earlier attempts to observe change during vulcanization is included. C. C. DAVIS

Watch-case vulcanizers. JOSEPH ROSSMAN. *India Rubber World* **78**, No. 4, 67-9 (1928); cf. *C. A.* **22**, 4273.—A description, from the historical point of view, of the development of this equipment. C. C. DAVIS

Measurement of the tread movement of pneumatic tires and a discussion of the

probable relation to tread wear. W. L. HOLT AND C. M. COOK. *Bur. Standards J. Res.* **1**, 19–28(1928).—*Lab. abrasion tests* to simulate road wear should use a non-linear abrasive movement since most of the tread surface is abraded by curved motion.

C. C. DAVIS

Studies on the reason for a rubber-like condition of matter (VON VEIMARN) **2.** Rubber-bonded abrasive articles (U. S. pat. 1,687,410) **19.** Protective paint from rubber (GRAY) **26.**

Latex composition. WILLIS ALEXANDER GIBBONS (to The Dominion Rubber Co., Ltd.). Can. 282,491, Aug. 14, 1928. Natural latex is concd. to a compn. contg. over 50% solids and preserved with ammonia, H_3PO_4 is added to neutralize the alkali, without coagulating the rubber content of the latex, the water is evapd., and all the solids contained in the latex are recovered. Cf. *C. A.* **22,** 3805.

Treating rubber latex. SOCIETÀ ITALIANA PIRELLI and U. PESTALOZZA. Brit. 284,608, Jan. 31, 1927. Latex is treated at a low temp. by adding small quantities of substances such as solns. or suspensions of salts of bi- or ter-valent metals, and is then heated to effect coagulation or thickening; *e. g.*, 0.15% of a slightly sol. Ca salt and 0.1% of ZnO suspended in "ammoniacal water," may be added to ammonia-preserved latex contg. 50% of rubber. At temps. of 20° or lower no coagulation occurs but on heating to 95–97° rapid coagulation is effected. Fillers, vulcanizing agents, etc., may be added and the process may be applied to the manuf. of molded articles, extruded tubes, etc.

Jelutong product. SHELDON S. YATES (to Chicle Development Co.). U. S. 1,685,797, Oct. 2. Jelutong latex is coagulated and the coagulant is melted and water is expelled to reduce the water content below 5%; the melted mass is then poured into molds and permitted to cool and is suitable for transportation and storage. Cf. *C. A.* **22,** 1705.

Electrodeposition of rubber, etc. DUNLOP RUBBER CO., LTD., P. KLEIN and A. HEALEY. Brit. 284,736, Aug. 4, 1926. The toughness of deposits of rubber, gutta percha and the like produced from dispersions is increased by incorporating with the aq. dispersions peptizing agents such as protective colloids, *e. g.*, soft soap, in excess of the quantities normally employed for protective purposes. Soft soap 6–12 g. may be used with each l. of latex contg. 30% rubber.

Rubber emulsions. J. M. A. TOUCHON. Brit. 284,244, Jan. 25, 1927. Rubber emulsions which may be used as substitutes for natural latex are prepd. by passing a thick rubber soln. together with water contg. an emulsifying agent through a high-speed emulsifying app. and removing the rubber solvent from the emulsified product by low-temp. distn. Numerous details are given.

Rubber compositions. E. YOSHIOKA. Brit. 284,912, May 19, 1927. A "buoyant rubber" for oil hose contains factis up to 3%, S 5%, an alk. soap insol. in mineral oils and melting at the vulcanizing temp. 1, diphenylguanidine 1% and rubber over 80%.

Regeneration of rubber. WALDEMAR SCHEITLAUER. Can. 283,709, Oct. 2, 1928. Ground waste rubber is regenerated by mixing with a NaOH soln. which has been in contact with cellulosic substances as used and discharged as a waste product in the production of viscose, and treating the mixt. in autoclaves in the usual way.

Spongy rubber. R. J. NOAR. Brit. 284,938, July 19, 1927. In manuf. of sponge-rubber articles, a vulcanized skin is formed on the surface of a mass of dough before gas is generated in the mass and the whole mass is then hot vulcanized. To effect the superficial vulcanization and skin formation a cold process may be used or there may be employed a "super-accelerator" such as piperidine piperidyl dithiocarbamate or tetramethyl-thiuram disulfide at a temp. below that at which gas is generated. Various details are given.

Surface layer of sponge rubber on rubber goods. SATARO MORIMOTO. U. S. 1,685,954, Oct. 2. A soln. of unvulcanized rubber mixed with materials such as $(NH_4)_2CO_3$, S and fillers which convert ordinary rubber into spongy rubber is applied to the surface of unvulcanized rubber goods and the assembly is then cured by a hot process.

Products of rubber with metallic salts. H. A. BRUSON (to Goodyear Tire & Rubber Co.). Brit. 285,071, Feb. 11, 1927; Can. 283,757, Oct. 2, 1928. Rubber is treated with metallic salts such as $SbCl_5$, $SnCl_4$, $TiCl_4$, $FeCl_3$, or BCl_3, to form addn. products which contain a plurality of hydrocarbon mols. linked together and from which the metal salt may be split off to obtain a product thought to be a polymer of rubber. Both the addn. product and the polymer absorb O from the air.

Rubber-surfaced roads, floors, etc. J. J. HORNE and C. F. HENDRICK. Brit. 285,203, Dec. 18, 1926. Structural features.

Ornamenting rubber articles. DUNLOP RUBBER CO., LTD., AND G. W. TROBRIDGE. Brit. 285,113, Oct. 14, 1926. Bathing caps or other rubber articles formed by electrophoretic deposition are treated in a press with heated embossed, engraved or stamped plates during or prior to vulcanization.

Apparatus for making rubberized cord sheet material. JOHN W. CLARK. U. S. 1,686,436, Oct. 2.

Tightening means for re-rubbering or molding pneumatic tires. MICHEL LAMOUROUX. Fr. 635,944, June 14, 1927.

Sulfurized oil compositions. A. DE WAELE. Brit. 284,415, Nov. 3, 1926. Vulcanized oil compns. are made by treating with S chloride, S thiocyanate, dithiocyanogen (or similar vulcanizing agent reacting energetically with glycerides of hydroxy unsatd. fatty acids) an ester of an unsatd. higher fatty acid in which one of the H atoms of the fatty acid residue is substituted by an electronegative atom or group which is less electronegative than the OH group, *e. g.*, Cl or the acetyl, formyl or carbonate group, *e. g.*, acetylated castor oil or acetylated oxidized or blown oils. Fillers and other substances may also be added.

Vulcanizing rubber. LORIN B. SEBRELL (to The Goodyear Tire and Rubber Co.). Can. 282,883, Aug. 28, 1928. A mixt. of rubber, a vulcanizing agent and a zinc salt of 1-mercapto-3,5-dimethylbenzothiazole is heated. Cf. *C. A.* **22,** 3806.

Vulcanized rubber. VULTEX, LTD. Ger. 462,858, June 28, 1928. Addn. to Ger. 391,635. Previously concd. latex of over 55% concn., preferably 60-70%, is vulcanized with the usual fillers, accelerators, etc.

Hot vulcanization of rubber. B. V. BUIZOV. Russ. 3831, Oct. 31, 1927. Alkali salts of trithiocarbonic acid are added to a mixt. of rubber, S and the customary ingredients in a rubber mass. The mixt. is then vulcanized as usual.

Hot vulcanization of a rubber mixture. B. V. BUIZOV. Russ. 3832, Oct. 31, 1927. Complex NH_3 salts of Ni, Cr, Cu and Co are added to a mixt. of rubber, ZnO, coloring compds. and fillers. This mixt. is vulcanized hot as usual.

Treating waste vulcanized rubber. DUNLOP RUBBER CO., LTD., D. F. TWISS and F. THOMAS. Brit. 284,829, Dec. 20, 1926. Comminuted scrap is admixed with S and with an "anti-ager" such as quinol, aminophenol aldol α-naphthylamine or other condensation product of the aldehydes and aromatic amines (suitably 1% each of the S and "anti-ager") and then subjected to heat and pressure (suitably in a "daylight press" for 30 min. at 150°).

Apparatus for molding and vulcanizing small rubber articles. DUNLOP RUBBER CO., LTD., H. WILLSHAW AND T. NORCROSS. Brit. 285,103, Oct. 7, 1926.

Molding and vulcanizing tires. J. R. GAMMETER (to B. F. Goodrich Co.). Brit. 285,359, Feb. 14, 1927. A plastic mixt. which may be formed of clay 100, water 40-50, and waterglass 1-2 parts is used for distending tires before vulcanization. An app. and various mech. details are described.

Apparatus for vulcanization of rubber. THE LIVERPOOL RUBBER COMPANY. Fr. 636,067, June 16, 1927.

Leather substitute. GOVERNMENT RUBBER TRUST "REZINOTREST." Russ. 4159, Sept. 15, 1924. Known accelerators of vulcanization, such as aliphatic hydroaromatic or heterocyclic amines or their salts or derivs. of dithiocarbamic acid, are added to a finely divided mixt. of rubber and leather, sulfur and oxides of the metals Ca, Mg, Zn, Pb, etc. This mixture is heated for the purpose of vulcanization at not over 110°.

CHEMICAL ABSTRACTS

Vol. 22. **December 10, 1928** **No. 23**

I. AUTHOR INDEX

("P" before a page number indicates "Patent")

NOTE.—In the transliteration of names originally written in Russian, the system followed so far as possible is that of *Nature* **41**, 396–7(1890), in which *v* is used instead of the *w* or *ff* of other spellings, *sh* instead of *sch*, *ch* instead of *tsch*, *i* instead of *j* or *y*, etc. Thus Pavlov, not Pawlow; Chugaev, not Tschugaeff. To make quite sure, users of the index should in such a case look under both spellings.

SUBJECT INDEX

KEY

In using this index the following should be borne in mind:

1. **Subjects,** not words, have been indexed.

2. **Abstracts,** not merely their titles, have been considered in indexing.

3. The small **superior numeral** which accompanies each page number designates the fraction of the page in ninths in which the subject being indexed is first considered. The printed matter only, exclusive of page headings, has been thus subdivided.

4. "P" before a page number indicates that the abstract is of a **patent.**

5. The **alphabeting of index headings** has been done on the basis of that part which comes before the comma in such headings as *Copper, metallurgy of* and *Phenol, p-nitro-*. *E. g.*, these headings come before the headings *Copper compounds* and *Phenol condensation products*, respectively.

6. **Organic compounds** are indexed on the basis of "parent compounds," or more accurately, "index compounds" (see Introduction), the names of substituent radicals following in alphabetical order. The system of naming organic compounds which has been used is outlined in the Introduction below. Esters and salts of organic acids are, in general, indexed under the names of the acids; notes in the index under the appropriate headings explain the few exceptions.

7. An **asterisk** (*) following the name of an organic compound entered in the index signifies that the name, or numbering, or both are the author's own and may not conform to the system of nomenclature used in this index. This sign is used where it has seemed inadvisable, owing to incomplete information, to attempt to make the name conform to the system, or where the author's name, differing widely from the one given to the compound by the indexer, is given as an extra entry.

8. A **dagger** (†), which follows the names of a few compounds, signifies that the entry is an extra one, the name being only slightly less favored than the one chosen for the other entry. The preferred name can be determined by reference to the Formula Index.

The desirability of making the index readily usable without the need of reference to an elaborate introduction has been held constantly in mind. Although an introduction seems desirable and should be helpful, nevertheless the index is dependent neither on the Key nor on the Introduction. Numerous cross references are given throughout the index, and notes appear in connection with certain headings. An examination of the Introduction, which follows, should be especially helpful to those interested in looking up organic compounds.

INTRODUCTION

General policy. The indexing of subjects, as opposed to word-indexing, has been emphasized. This avoids omissions, scattering and unnecessary entries; with the abundant cross-references used it means that one should be able to find all of the references on any subject with certainty and with a minimum of effort. The words used as subject headings or in modifying phrases are not necessarily to be found in the abstracts but an expression of the idea suggested will be found within or beginning in the ninth of the page designated by the small superior numeral following the page number. Chemical compounds have been named and entered systematically; the system used is outlined below. All new compounds and all elements, compounds and other substances for which new data are given have been indexed, with the single exception of new compounds for which no names or structures have been given. Such compounds are entered only in the Formula Index. The Subject Index is in no other respect altered because of the Formula Index.

Modifying phrases. In writing such phrases for the entries under any heading the words have been arranged so that the idea considered to be the most important is expressed at the beginning whenever feasible and this procedure, as well as the selection of the words for this purpose, has been governed by numerous formulated general principles and specific rules. *E. g.*, "detection of" has been used consistently whenever correct at the beginning of the modifications in indexing subjects treated from a qualitative analytical point of view, instead of permitting a scattering under such additional phrases as "test for," "reaction for," etc., regardless of what words may have been used in the text. In the case of appropriate headings the selection of first words for modifications has been made on the basis of a definite system of classification. Under a few large headings two or more entries have been made on indexing a subject in a single abstract in case two or more ideas could be used equally well to start the modifying phrase. In alphabeting modifying phrases prepositions at the beginning have been ignored.

References to fractions of the page. One can readily estimate ninths of a page with considerable accuracy by placing the fore or middle finger one-third of the distance from the top of the printed matter on the page and the thumb one-third of the distance from the bottom, a procedure very easily carried out.

Inorganic compounds. Simple inorganic compounds are entered under the usual names. In indexing compounds of iron, gold, copper and tin such headings as *Iron sulfates*, under which the "ous" and "ic" salts are entered, have been used rather than headings beginning with "ferric(ous)," "auric(ous)," "cupric(ous)," or "stannic(ous)." Acid salts, such as NaH_2PO_4, are entered under such headings as "*Sodium phosphates*." With the exception of a few common compounds, such as carbon dioxide and carbon monoxide, compounds of a given element with another or with a definite radical, which differ only in valence relations, are grouped. *E. g.*, the various oxides of nitrogen are grouped under the heading "*Nitrogen oxides*" and classified there Complex inorganic compounds which cannot be given definite names satisfactory for indexing are usually indexed under the heading which represents the class of compounds concerned and under a heading beginning with the name of the significant element. *E. g.*, dichlorotetraamminecobaltic chloride would be indexed under "*Ammino compounds*" and under "*Cobalt compounds*." The Formula Index, which follows the Subject Index, should be particularly helpful in locating complex compounds.

Organic compounds. The system used for naming and indexing organic compounds is the same as that in use starting with the 1916 volume. An explanation of it by Austin M. Patterson and Carleton E. Curran, who are its originators, has appeared in another

journal of the Society.[1] The system is based on existing usage and follows this as far as is practicable, so that a great many familiar names are unaffected. Only the general principles will be given here, but in the index itself will be found abundant cross references and also notes under *Alcohols, Ketones,* etc., indicating how compounds of these classes are named.

1. The "chief function" of a compound is expressed *in the main part of the name* wherever possible, and not as a substituent, thus: Pyrrolecarboxylic acid, not carboxypyrrole; ethyl alcohol or ethanol, not hydroxyethane; pentanone, not ketopentane.

2. In compounds of mixed function, the chief function is determined from the following order of precedence:[2] *"onium" compounds, acid* (carboxylic first), *acid halide, amide, imide, aldehyde, nitrile, ketone, alcohol, phenol, mercaptan, amine, imine, ether, sulfide* (and *sulfoxide* and *sulfone*). Thus, hydroxybenzonitrile, not cyanophenol; aminophenol, not hydroxyaniline.

3. A multiple chief function is expressed where feasible as -diol, -dicarboxylic acid, etc., rather than as hydroxy—ol, carboxy—acid, etc. But amino and imino groups attached to cyclic bases are treated as substituents; as, aminopyridine.

4. The index compound should be as large, and the substituents as small, as is practicable in conformity with the above rules; as, ethylbenzene, not phenylethane. But such names as diphenylethane and triphenylcarbinol are exceptions. When the chief function is in a side chain attached to a complex nucleus, "additive" names are preferred in order to harmonize 1 and 4; thus, naphthaleneacetic acid, not naphthylacetic acid (with the result that the compound is indexed with other naphthalene derivatives instead of under acetic acid; see 5).

5. The main part of the name with its functional ending, if any, is placed *first* in the index, the names of substituents following; thus, chloroacetic acid would appear in the index as *Acetic acid, chloro-* and dihydroxyanthraquinone as *Anthraquinone, dihydroxy-*. The part thus placed first is called the "index compound"; it may or may not be the "parent compound" (in the second example the parent compound is anthracene).

6. Names in which two functions are expressed in the index compound, as propanolone, cyclopentanonecarboxylic acid, are avoided, except that a few very common ones, such as phenolsulfonic acid, are used (indicated by cross-references).

7. The names of the substituent radicals in the name of a compound are arranged *in alphabetical order;* as, *b*enzyl*e*thyl*m*ethyl*p*henylammonium chloride. The number of radicals of each kind does not affect the order (*e. g., benzyl* precedes *ethyl* no matter how many of each are present); but the compound name of a substituted radical is treated as a unit with its own alphabetic position; thus *dimethylamino,* Me_2N-, follows *benzyl* but precedes *ethyl.* When the complete name has been formed, it is alphabeted as any other word.

8. Parentheses, brackets and even braces are used where necessary to mark off complex radical names.

9. Familiar methods of numbering are employed (Greek letters for acids, alcohols, etc., and for side chains; arabic numerals for Geneva names and rings). The numbering of complex nuclei is shown in the index under the parent compounds; it is practically identical with that of Richter's "Lexikon" so far as that work goes. For the more recently discovered forms the "Proposed International Rules for Numbering Organic Ring Systems"[3] have been adopted as a standard.

10. When two or more numberings are equally indicated that one is chosen which

[1] Patterson and Curran, *J. Am. Chem. Soc.*, **39**, 1623–38(1917).

[2] This order is an attempt to express, not the relative chemical importance of functions, but general usage in selecting one of them for the ending of the name.

[3] Patterson, *J. Am. Chem. Soc.*, **47**, 543–61(1925).

gives the smallest number or numbers for the *chief function, then for double bonds* if these must be regarded, *then for triple bonds, then for point of attachment* (doubled molecules), *then for substituents.*

11. Unnecessary numbers are avoided: thus, in Δ^3-1-cyclohexanol the 1 is not needed because by the rules in paragraph 10 the OH group is assumed to be in position 1.

12. Numbers in parentheses are used to indicate the position of entering hydrogen necessary to the existence of the compound; thus, 4(3)-quinolone is equivalent to 3, 4-dihydro-4-ketoquinoline.

13. Doubled molecules or radicals are indicated by names commencing with *bi-* (as, *o,o'*-biphenol, biphenyl, $\Delta^{4,4'}$-bipiperidine). *Bis-* is used for like molecules united by a bivalent radical and for double complex expressions; as, methylenebisphenol, bis(dimethylamino)-.

In using the *cross references*, the *general* nature of many of them should be kept in mind; thus, the reference "*Benzene, ethoxy-*. See *Phenetole*" is applicable not only to this compound itself but to derivatives, which are indexed under it rather than under *Benzene*.

ORGANIC RADICALS

An extensive list of preferred names for organic radicals was given in the 1927 Index in a place corresponding to this and also in the Introduction of the Second Decennial Subject Index. With few exceptions they are the ones in common use. Attention is here called merely to the preferred names for some radicals having more than one name in the literature and to some radical names recently adopted.

BY NAMES

acenaphthenyl $C_{12}H_9$—
acetyl CH_3CO—
acridyl $C_{13}H_8N$—
acrylyl $CH_2{\cdot}CHCO$—
amyl C_5H_{11}—
anisal *p*-$MeOC_6H_4CH$:
arsono $(HO)_2OAs$—
arsyl H_2As—
arsylene HAs:
asaryl 2,4,5-$(CH_3O)_3C_6H_2$—
benzal C_6H_5CH:
benzenyl $C_6H_5C\vdots$
benzilyl $Ph_2C(OH)CO$—
benzofuryl C_8H_5O—
benzohydryl Ph_2CH—
boryl O.B—
1,4-butylene—$(CH_2)_4$—
camphanyl (*from camphane*) $C_{10}H_{17}$—
camphoroyl (*from camphoric acid*) $C_8H_{14}(CO)_2$·
camphoryl (*from camphor*) $C_{10}H_{15}O$—
camphorylidene (*from camphor*) $C_{10}H_{14}O$:
carbamido H_2NCONH—
carbamyl H_2NCO—
carbethoxy EtOOC—
carbomethoxy MeOOC—
carbonyl OC=
carbyl —C—
cetyl $Me(CH_2)_{15}$—
cinnamal PhCH:CHCH·
citral (*from citraldehyde*) $C_9H_{15}CH$:
cresotyl (*from cresotic acids*) $(OH)(CH_3)C_6H_3CO$-2,3—, etc.).
cresyl $(OH)MeC_6H_3$—
cumal *p*-$Me_2CHC_6H_4CH$:
epoxy —O—
ethinyl $HC\vdots C$—
ethinylene —$C\vdots C$—
ethylene —CH_2CH_2—
fenchyl (*from fenchyl alcohol*) $C_{10}H_{17}$—
fluorylidene (*from fluorene*) $C_{13}H_8$:
formyl OHC—
fural C_4H_3OCH.
furyl C_4H_3O—
furylidene (*2 isomers*) $\overline{\underset{4}{CH}\ \underset{5}{CH}\ \underset{1}{O}.\underset{2}{CH_2}\ \underset{3}{C}}$·
guanido $H_2N.C(.NH).NH$—
guanyl $H_2N.C(.NH)$—
hippuryl $PhCONHCH_2CO$—
indylidene (*from indole*) C_8H_7N.
isonitro HOON:
isonitroso HON:
isopropenyl $MeC(.CH_2)$—
keto O.
mercapto HS—
mesityl (*from mesitylene*) 3,5-$(CH_3)_2C_6H_3CH_2$—
methionyl —$SO_2CH_2SO_2$—
naphthal $C_{10}H_7CH$:
naphthylidene $C_{10}H_8$.
oxy —O—
perthio (*replacing O only*) S:S:
pheracyl $PhCOCH_2$—
phenacylidene PhCOCH:
phenanthrylene (*from phenanthrene*) $C_{14}H_8$:
phenylenedisazo —$N{:}NC_6H_4N{:}N$—
phthalidene (*from phthalide*) $\overline{C_6H_4CO.OC}$=
phthalidyl (*from phthalide*) $\overline{C_6H_4CO.O.CH}$—
piperonyl 3,4-$(CH_2O_2)C_6H_3.CH_2$—
pivalyl (*from pivalic acid*) $(CH_3)_3CCO$—
propenyl MeCH:CH—
propenylidene $CH_3CH{:}C$:

RING INDEX

The following index of *ring complexes* is arranged as shown by the bold-face figures: Class I, with single figures indicating simple rings of 3, 5, etc., members; Class II, two figures denoting double rings of 3 and 4, 3 and 5, etc., members; then the triple and still more complex rings. Under each combination of figures the kind and number of atoms in the ring or rings are expressed in formulas. These formulas are arranged so that their initial rings are in the same order as in the Formula Index (see Key at the beginning of it). If the initial rings are alike the second rings of the formula are considered, and so on. By this means the reader will be able to learn the name used in the index for the simplest parent compound containing any particular ring or combination of rings and by turning to this name in the index he will find the compounds listed and, perhaps, cross references to names of derivatives. Rings which are united but which have no atoms in common (*e. g.*, biphenyl) and "spiro" compounds[1] which are characterized by two rings having but one atom in common are not regarded as ring complexes nor included in this index

To illustrate: **6,6,6,** C_4N_2-C_6-C_6 Benzophthalazine
Phenazine

This designates (1) a ring system of three components, each of six members; (2) the first is heterocyclic, containing four carbon atoms and two nitrogen atoms and the other two are carbocyclic rings of six atoms each; (3) parent compounds of this configuration will be found in the index under the two names given. If derivatives are indexed a structural formula will be found with the proper numbering and also appropriate cross references to derivatives having other common names, if any such are in the index.

It should be noted that the classification is made with reference to the number of smallest rings which, placed together, will constitute the plane formula. Thus hexamethylene tetramine is treated as a 6,6,6 complex although a fourth six-membered ring (composed of atoms from the three six-membered rings) is also present.

III. FORMULA INDEX

KEY.

In using this index the following should be borne in mind:

1. The Formula Index is **supplementary** to the Subject Index; in no sense does it replace any part of the latter except that most of the organic compounds that were not named in the original papers are entered in the former only.

2. **Inorganic as well as organic compounds** have been entered.

3. **Entries under their own formulas** are made for all strictly inorganic and strictly organic compounds and for the true organic derivatives of organic compounds, both addition compounds and true reaction derivatives (this includes esters, hydrazones, methohalides, oximes, picrates, semicarbazones, etc.). Inorganic salts of organic acids and inorganic addition compounds of organic compounds (hydrohalides, chloroplatinates, perchlorates, sulfates, etc.) are not given separate entries but are indicated in modifying phrases under the formulas of the compounds from which they are derived (under the acid in the case of a salt). Salts of formic, acetic and oxalic acids are exceptions; these are entered as such.

4. The **arrangement of symbols in formulas** is alphabetical except that in carbon compounds C always comes first, followed immediately by H if hydrogen is also present.

5. The **arrangement of formulas** is also alphabetical except that the number of atoms of any specific kind influences the order of compounds. *E. g.*, all formulas with 1 C come before those with C_2, thus: CCl_2O, CCl_4, $CHCl_3$, CHN, CHNO, CH_2Br_2, CH_2O, CH_3Cl, CO, C_2Ca, $C_2H_4O_2$.

6. The **arrangement of entries under any heading** is strictly alphabetical according to the preferred names of the isomers.

7. **Entries consist of** (*a*) the formula (in bold-face type), (*b*) the name as it has been entered in the Subject Index (in light-face Roman type; *it should be noted particularly that the part of the entry in this type is the exact equivalent of the formula given*), (*c*) occasionally a modifying phrase or word such as "Ca salt" or "hydrochloride" (in italics, different type being used to set off that part of a compound being indexed which is not represented in the formula used; see ¶ 3 above), (*d*) the page reference and (*e*) the fraction of the page in ninths (indicated by a small superior numeral) in which the compound will be found.

8. **Cross-references** are to the Subject Index.

9. **Water of hydration** is not made a part of the formulas indexed but is usually given in light-face type following the formulas.

10. **Polymers** having different names and recognized as different substances, *e. g.*, acetaldehyde and paraldehyde, are all entered under their accepted formulas. But definite compounds for which different polymeric formulas are in use are entered under the simplest formula only with cross-references under the polymeric formulas.

11. **A straight line,** thus—, used under some headings to avoid repetition of names, always stands for the name of the "index compound," *i. e.*, that part of the preceding name (inverted) which comes before the comma.

12. "P" before a page number indicates that the abstract is of a **patent.**

13. The **names beryllium** (Be), **columbium** (Cb) **and hafnium** (Hf) are given preference over glucinum (Gl), niobium (Nb) and celtium (Ct), respectively, for these elements.

The Key to a formula index is necessarily lengthy. It would not be correct to conclude from this that this index is difficult to use. Experience is to the contrary.

INTRODUCTION.

General purpose and policy. The location of chemical compounds in an index by names is at times uncertain because names vary and in the case of complex compounds may be difficult to ascertain. New compounds are constantly being prepared, which, if named at all, may receive more than one name which is justified from one point of view or another and the possibilities of incorrect names are great. Since the kinds and number of component atoms of a chemical compound are unvarying characteristics the supplementary Formula Index to *Chemical Abstracts* is published for the purpose of eliminating this element of uncertainty in the Subject Index. Except that many unnamed compounds are no longer entered under the heading "Compound," the Subject Index is in no way altered on account of the Formula Index. In the Subject Index related compounds are *grouped* rather effectively and to good use by the present system of indexing on the basis of "parent compounds" or more accurately "index compounds"; in the Formula Index the certain location of *individual* compounds is the primary consideration. The Subject Index is more convenient to use in some respects and it frequently contains more information in the form of modifying phrases. The repetition of modifying phrases in the Formula Index beyond necessary brief phrases to indicate derivatives has been avoided as unnecessary for the accomplishment of the real purpose of this index, as stated above, and as inconsistent with necessary economy. Isomerism is not indicated in the Formula Index in cases in which the names differ only in position numbers or letters but it always is in the Subject Index when known. Ready reference to the Subject Index for the purpose of locating information regarding related compounds is made possible by the use in the Formula Index of names following the formulas written exactly as they appear in the former index.

All new compounds and all compounds for which new data are given have been entered. Most of the compounds have been entered under their own formulas. Some departure from a policy of making separate formula entries for derivatives of all kinds is reasonable and accords with custom. The only departures in this index (see ¶3 of the

Key) have been in classes of compounds the nature of which would be more than likely apparent to the investigator. The interest in a salt of a complex organic acid, for example, is likely to be mainly in the acid and it is considered more valuable to have the record of it under the formula of the acid for the use of searchers looking up that acid.

In the case of unnamed organic compounds, where possible, the class, as acid, source and melting or boiling point have been given.

Cross-references to the Subject Index have been used for all simple inorganic compounds, for all minerals of definite composition and for the organic compounds more commonly met with, in general whenever it seemed likely that users of *Chemial Abstracts* would predominatingly refer to the Subject Index.

The system. The system, as described in the Key, is, with slight modifications, that worked out by Dr. Edwin A. Hill[1] and used by the Classification Division of the U. S. Patent Office. This system is preferred to the system of Richter's Lexikon because of its greater simplicity and its applicability with equal fitness to inorganic as well as to organic compounds.

$C_{18}H_{24}N_4O_7$ Pyridine, 1,2,3,6-tetrahydro-4-iso-propenyl 2,2,6,6-tetramethyl-, picrate, 1592[1].

$C_{18}H_{24}N_4O_8$ Cyclohexanone, 2 - (1 - piperidyl-methyl)-, picrate, 591[7].

$C_{18}H_{24}O$ Acetophenone, *α*-(2-*p*-menthylidene)-, 1576[1].
Carvomenthol, 2-phenylethinyl-, 1575[8].
5-Naphthacenol, 1,2,3,4,6,6a,7,8,9,10,10a,11-dodecahydro-, 1587[2].

$C_{18}H_{24}O_3$ Ammoresinol, 2437[9].
Carvomenthone, 3-(hydroxymethyl)-, ben-zoate, 2935[9].

$C_{18}H_{24}O_4$ Phthalic acid, monomenthyl ester, 3156[6].

$C_{18}H_{24}O_{11}$ Primeveroside of salicylic acid, 2360[6].

$C_{18}H_{25}BrO_5$ Propionic acid, *β*-(5-bromo-2,4-di-methoxybenzoyl)-*α*,*α*-diethoxy-, Et ester, 2154[9].

$C_{18}H_{25}NO$ *p*-Phenetidine, *N*-2-camphanylidene-, and salts, 408[6].

$C_{18}H_{25}NO_3$ Δ^1-3-Pentenone, 1-(3,4-dimethoxy-phenyl)-5-(1-piperidyl)-, -*HCl*, 963[9].

$C_{18}H_{25}NO_4$ Nipecotic acid, 1-(*γ*-hydroxypropyl)-, Et ester, benzoate, -*HCl*, 31[6].

$C_{18}H_{25}N_3O_2$ Borneol, *α*'-benzoyl-, semicarba-zone, 67[9].

$C_{18}H_{26}Br_2CoN_6O_4$ + 2H_2O, 1291[1].

$C_{18}H_{26}CaN_2O_8$ See *Ipral.*

$C_{18}H_{26}Cl_2N_4O_6$ Crotonic acid, *N*, *N'*-ethylene bis[*β*-amino-*α*-chloroacetyl-, di-Et ester, 221[2].

$C_{18}H_{26}CoN_{11}O_{11}$, 551[2].

$C_{18}H_{26}N_2$ Benzo[1,2-*γ*:4,5-*γ*']dipyrrole, 2,4,6,8 tetrahydro - 1,2,4,4,5,7,8,8 - octa-methyl-, 2561[9].
